Yet with all this, our agricultural industry is said to be languishing or overdone, and the spring of 1870 finds our farmers almost exhausted of funds, and our financiers seeking various and diverse remedies to increase the volume of currency—to "make money easy." But their efforts in that direction will be in vain. *The lack of diversified farming* and the want of a disposition among our own people to enter thereupon, is what's the matter—and nothing else. Diversified farming encourages industry and application on the farm; it leads to intelligent action in the selection of crops and in their application to the soil, as well as their proper rotation; it economizes the farmer's labors and expenditures; keeps money in the State that under our present system goes out by thousands and millions to support farmers in other parts of the country; it tends to subdivision of our lands into smaller sections, whereby they are more thoroughly tilled; it fills up the State with an industrious population; furnishes a home interchange of products, encourages manufactures, and thereby greatly enlarges the market for its own surplus.

The growing of any one crop, to the exclusion of others, is always to be deprecated. It stakes success on a single enterprise; it is an exhaustive system of agriculture; it affords no opportunities for the general average which, under the diversified system, makes profit and loss a uniform success; it crowds the work of the entire year into a few months, thereby necessitating bad economy in labor; it compels the farmer of small capital to annually hypothecate his crop at ruinous discounts; it is a short-sighted, ruinous policy for the great mass of producers in every possible aspect in which we may view it; in short, it is the very antipodes, in its results, of diversified farming.

There is scarcely an intelligent farmer in the State that will not subscribe to these propositions, and we frequently meet with those who curse their folly for having pursued this course in the past, and who express the wish that they had diversified their crops and labor. Yet, as a general thing, these very persons still continue to go on in the same old routine, their lands growing worse and worse, their crops growing less and less—in fact, with ruin staring them in the face! Why they do so it is difficult to say; whether it is impulse or listlessness, or a feeling of discouragement at the magnitude of the task involved in the change, or all combined, we leave for others to judge. In many places, no doubt, a general system of irrigation is essential to the desired change; yet much might be done independently, with or without drainage, and it will be only by such independent action, carried out to an extent sufficient to prove its practicability and economy, that we can hope for any general improvement in this direction.

Animal Fat—Its Significance.

The fat of man or animals is an oily matter, of itself unendowed with life or sensibility. It is contained in cells much as honey is in the comb. The walls of these cells possess sensitiveness, and are so organized as to have the power of adding to or taking from the amount of oily matter, or fat, which they may at any time contain.

The use of fat is to fill up crevices, as it were, in the body, and facilitate the movement of parts one upon another. It also serves as a sort of internal nutriment, wherewith the animal system may be sustained, whenever it may be in a position where it cannot obtain its usual supply of food, or when the digestive organs fail to act promptly. It is, in fact, a sort of *balance wheel*, which serves to average the nutritive supply to the system, whenever, from any cause, that supply is made irregular.

Whenever, from any cause, there is an undue accumulation of fat in the system, it clogs and impedes; instead of facilitating the motions of the parts of the body, it becomes a burthen. An over-fat horse is unfit for speed or easy labor, from the fact that his limbs are clogged—he has a useless burthen to carry. A fat animal suffers more from loss of blood than one in good working condition. A fat man will sooner faint from the abstraction of blood than a lean man.

Plumpness from fatness is not always a sign of strength and health. Horse-dealers well understand this. It is often the case that such persons, by a careful manipulation of food and exercise, *will so fill up with fat the crevices* in a broken-down animal, as to conceal most or all its outward imperfections. Fat thus becomes the horse-dealers' putty; for by it, like the coach or cabinet-maker, he makes the article which he has for sale appear more perfect than it really is. The eye of the experienced horseman, however, is generally able to detect the cheat. Such a person, quietly feeling the ribs and along the crest, determines at once, by the eye and hand, that which one, with less experience, can discover only on actual trial.

An ox takes on fat more readily than a horse, and when forced in that direction, the fat of the bovine is less likely to assume an unhealthy form, or accumulate, in excess, in undesirable localities. In young horses, fat is mostly deposited externally—upon the superficial muscles; but horses seven or eight years old and upwards are more disposed to accumulate fat inwardly—as about the kidneys and bowels. A horse sometimes shows very little fatness outwardly when he is "loaded with fat" inwardly.

Fatty matter deposited among the muscles of an animal—between their fibers—renders the flesh flabby, and is not an indication of strength. Such fatness, however, is desirable in beef intended for the table. The ox, as we have already said, takes on fat in that manner readily, the horse with difficulty. This appears to be a wise distinction of Nature between the two animals; and may not this fact add another and important inference to the teachings of Holy Writ, that the horse was never intended as food for man?

A good horse is less made up of fatty substance than a good ox. Both, however, should have large bones and joints and muscles; for in these alone are found their strength and physical powers. Large bones are more essential, however, to the horse than to the ox, for the reason that without them there will be a lack of speed. All our best racers have been large-boned horses. We will endeavor, next week, to show where fat and flesh come from.

The Willamette river is stated to be higher now than at any time during the winter or in any year, at this season, as far as known.

What I Know of Farming—No. 10.

The Possibilities of Irrigation.

I have given an account of my poor, little experiment in irrigation, because it is one which almost every farmer can imitate and improve upon, however narrow his domain and slender his fortune. I presume there are half a million homesteads in the United States which have natural facilities for irrigation at least equal to mine; many of them far greater. Along either slope of the Alleghenies, throughout a district at least a thousand miles long by three hundred wide, nearly every farm might be at least partially irrigated by means of a dam, costing from twenty-five to one hundred dollars; so might at least half the farms in New England and our own State. On the prairies the plans must be different, and the expense probably greater, but the results obtained would bounteously reward the outlay. I shall not see the day, but there are those now living who *will* see it, when artesian wells will be dug at points where many acres may be flowed from a gentle swell in the midst of a vast plain, or at the head of a fertile valley, expressly, or at least mainly, that its waters may be led across that plain, adown that valley, in irrigating streams and ditches, until they have been wholly drunk up by the soil. I have seen single wells in California that might be made to irrigate sufficiently hundreds of acres, by the aid of a reservoir into which their waters could be discharged when the soil did not require them, and there retained until the thirsty earth demanded them.

An old and successful farmer in my neighborhood affirms that water is the cheapest and best fertilizer ever applied to the soil. If this were understood to mean that no other is needed or can be profitably applied, it would be erroneous. Still, I think it is clearly true that the annual product of most farms can be increased, and the danger of failure averted, more cheaply by the skillful application of water than by that of any other fertilizer whatever, plaster (gypsum) possibly excepted.

I took a run through Virginia last summer, not far from the 1st of August. That State was then suffering intensely from drouth, as she continued to do for some weeks thereafter. I am quite sure that I saw on her thirsty plains and hillsides not less than three hundred thousand acres planted with Indian corn, whereof the average product could not exceed ten bushels per acre, while most of it would fall far below that yield, and there were thousands of acres that would not produce one sound ear! Everyone deplored the failure, correctly attributing it to the prevailing drouth. And yet I passed hundreds, if not thousands of places, where a very moderate outlay would have sufficed to dam a stream or brooklet issuing from between two spurs of the Blue Ridge, or the Alleghenies, so that a refreshing current of the copious and fertilizing floods of winter and spring, warmed by the fervid suns of June and July, could have been led over broad fields lying below, so as to vanquish drouth and insure generous harvests. Nay, I feel confident that I could in many places have constructed rude works in a week, after that drouth began to be felt, that would have saved and made the corn on at least a portion of the planted acres through which the now shrunken brooks danced and laughed idly down to the larger streams in the wider and equally thirsty valleys. Of course, I know that this would have been imperfect irrigation—a mere stop-gap—that the cold spring-water of a parched summer cannot fertilize as the hill-wash of winter and spring, if thriftily garnered and warmed through and through for sultry weeks, would do; yet I believe that very many farmers might, even then, have secured partial crops by such irrigation as was still possible, had they, even at the eleventh hour, done their best to retrieve the errors of the past.

For the present, I would only counsel every farmer to give his land a careful scrutiny with a view to irrigation in the future. No one is obliged to do any faster than his means will justify; and yet it may be well to have a clear comprehension of all that may ultimately be done to profit, even though much of it must remain long unattempted. In many cases, a stream may be dammed for the power which it will afford for two or three months of each year, if it shall appear that this use is quite consistent with its employment in irrigation, when the former alone would not justify the requisite outlay. It is by thus making one expense subserve two quite independent, but not inconsistent purposes, that success is attained in other pursuits; so it may be in farming.

As yet, each farmer must study his own resources with intent to make the most of them. If a manageable stream crosses or issues from his land, he must measure its fall thereon, study the lay of the land, and determine whether he can or cannot, at a tolerable cost, make that stream available in the irrigation of at least a portion of his growing crops when they shall need water and the skies decline to supply it. On many, I think on most, farms situated among hills, or upon the slopes of mountains, something may be done in this way—done at once, and with immediate profit. But this is rudimentary, partial, fragmentary, when compared with the irrigation which yet shall be. I am confident that there are points on the Carson, the Humboldt, the Weber, the South Platte, the Cache de-Pouder, and many less noted streams, which thread the central plateau of our continent where an expenditure of $10,000 to $50,000 may be judiciously made in a dam, locks and canals, for the purposes of irrigation and milling combined, with a moral certainty of realizing fifty per cent. annually on the outlay, with a steady increase in the value of the property. If my eye did not deceive me, there is one point on the Carson, where a dam that need not cost $50,000 would irrigate one hundred square miles of rich plain, which, when I saw it, eleven years ago, grew aught but the worthless shrubs of the desert, simply because nothing else could endure the intense, abiding drouth of each Nevada summer. Such palpable invitations to thrift cannot remain forever unimproved.

In regions like this, where summer rains are the rule rather than the exception, the need of irrigation is not so palpable, since we do or may secure decent average crops in its absence. Yet there is no farm in our country that would not yield considerably more grain and more grass, more fruit and more vegetables, if its owner had water at command which he could apply at pleasure and to any extent he should deem requisite. Most men, thus empowered, would at first irrigate too often and too copiously; but experience would soon temper their zeal, and teach them

> "The precious art of Not too much;"

and they would thenceforth be careful to give their soil drink, yet not drown it.

Whoever lives beyond the close of this century, and shall then traverse our prairie States, will see them whitened at intervals by the broad sails of windmills, erected over wells, whence every gale or breeze will be employed in pumping water into ponds or reservoirs, so located that water may be drawn therefrom at will and diffused in gentle streamlets over the surrounding fields to invigorate and impel their growing crops. And, when all has been done that this paper faintly foreshadows, our people will have fairly indicated, not by any means exhausted, the beneficent possibilities of irrigation.—*Horace Greeley.*

Japanese Chesnut Trees.

Mr. Keudo's treatise upon silk, tea and other Japanese products, elsewhere more particularly noticed, gives the following interesting facts with regard to the Japanese chesnut: "They have in Japan four or five different kinds of chesnut trees, bearing nuts of a good, and some of a most delicious flavor. Some of these trees grow to a height of forty feet, and have a diameter of three feet, while others are of a dwarf species, very bushy, but not reaching a height of more than three or four feet. The species is an evergreen, the nuts, which are, also, of a diminutive size, though of very superior excellence, ripening upon the tree all the year round. The larger trees have wide spreading branches, which they send out about ten feet above the ground. The wood of the Japanese chesnut is hard, different from the European and American tree, and is used for building and mechanical purposes. The nuts are enclosed in thickly spinated burs; those grown upon the larger trees being from an inch and a quarter to an inch and a half in diameter, resembling the French chesnuts, though somewhat larger and of scarcely so fine a quality.

All these varieties of the chesnut tree grow well in California, as shown by actual trial, it being thought that they will bear in two years from the planting of the young trees, and in three where grown from the seed. When once rooted they are a hardy tree, and unless destroyed by accident, will flourish in almost any kind of soil, and bear fruit for centuries; wherefore, they could not fail to yield large profits in California, where chesnuts now sell at rates varying from fifty to seventy-five cents per pound, many of them being old and unsound at that.

St. Louis Wheat Trade Classification.

The following classification of wheat is in use at the Merchants' Exchange, St. Louis: "Choice" must be bright, sound, plump, dry and well cleaned, pure *white* winter, to weigh at least sixty-two pounds to the measured bushel. No. 1 white must be sound, dry, well-cleaned, pure white winter wheat, that will weigh at least sixty pounds to the measured bushel. No. 2 white must be round, dry, white winter wheat, reasonably well cleaned, weighing not less than fifty-nine pounds. No. 1 red must be sound, well cleaned, dry red or red and white mixed winter wheat, free from rye, and weighing at least sixty pounds. No. 2 red must be sound, dry, reasonably well cleaned, red or red and white mixed, weighing not less than fifty-nine pounds. No. 3 red must be as No. 2, free from must, and weigh at least fifty-seven pounds. "Choice" red must be bright, sound, plump, dry and well-cleaned red or red and white mixed winter wheat, weighing at least sixty-two pounds per measured bushel. "Rejected" will include all damp, rough, either very smutty or unground wheat of any weight, and all light, trashy, or dirty thin wheat falling below No. 3 wheat.

All quotations made according to the above classification will be considered bulk wheat in elevator.

Farmers generally suffer much unnecessary loss from badly-cleaned wheat, inasmuch as a very small quantity of poor wheat degrades even a larger quantity of good wheat to the lower grade. Farmers should clean their wheat thoroughly, and thereby secure the highest market rates, and save the refuse for the hog pen or stable. It is poor economy to feed very dirty, and especially *smutty* refuse, to the chickens; better give it to the hogs.

New Agricultural Products.—Specimens of Chinese bamboo and Japanese plums, grown from imported roots, have been exhibited in Los Angeles, and are attracting much attention. Our next Institute exhibition in this city will doubtless contain a large list of new agricultural products for California.

Coffee.—About 713,000,000 pounds of coffee are annually produced in the world, of which Brazil furnishes 400,000,000, or over one-half, and the United States consumes nearly one-third.

Graded Stock.—Twenty-two head of English graded milch cows were shipped last week from Marysville to Mr. Summer,s a dairyman at Reno.

"In all places where the hot dry breath of constant drouth prevails through the summer, grapes are small but very sweet. Where a surplus of moisture and cool winds prevail, they are sour and mildew. I am constrained to think that the sunny hills, through the eastern part of Alameda county, are admirably adapted to the culture of the grape."

We find in the Scientific Press of our city, this most wonderful discovery relative to the culture of the grape. Its very lucid (?) description of the causes of the sweetness and acidity found in wine, should entitle the author to a professorship in our Agricultural College!—*California Farmer.*

Our contemporary writes at random. There is nothing said, or even hinted at, in the paragraph quoted from this paper, or in any portion of the article from which it is taken, about "the causes of the sweetness and acidity found in wine," nor is there any reference whatever made to *wine* in the article in question. Hence, the "very lucid (?) description," to which reference is made by the *Farmer*, must have existed only in the brain of the editor of that paper.

The paragraph quoted from the Scientific Press is strictly correct, both in fact and theory, and contains important truths, which ought to be familiar to every grape-grower, as our contemporary will see and recognize, if he will carefully re-peruse the article in question.

* * *

Returned.—We print in another column the concluding letter of a series written for the Press by Mr. Paul. In these Mr. P. has, in a clear, unprejudiced manner, spoken of things as he saw them; and it must be interesting, as well as instructive, to our Colorado friends to see how a Californian is impressed with their Territory. In these letters there has been neither indiscriminate blame nor unqualified praise, but plain language, such as cannot but benefit any locality. Mr. Paul returned to this city last week and has published a pamphlet, which states the claims, the philosophy and the practical workings of his process, and contains strong certificates as to its value.

The Remedy.

In our last issue we endeavored to explain the cause of the great neglect of the agricultural and manufacturing interests of the State, and gave some reasons why emigrants failed to reach this coast in numbers commensurate with the natural advantages which it presents. To-day we propose to consider the remedy.

The only proper and available road out of the unfortunate condition in which we find the great industrial interests of this State involved, is for our people to come down to legitimate business themselves—to that in which sure gain awaits every man of energy, economy and perseverance. Our mechanics and laboring men should save their earnings until they can command an amount sufficient to go into the valleys and mountains, and secure a reasonable amount of land, and have sufficient left to stock the same and wait for the return of crops, or product of stock. Our mechanics and manufacturers should husband their resources, keep out of speculations, in which nine out of ten lose, and coöperate together in the establishment of manufacturing, mechanical and other industrial operations. Our bankers should cease to encourage speculations, confine themselves to a regular banking business, and extend facilities to such legitimate operations as have real merit, and a tendency to develop values and encourage industry. Banks should also be established for the special purpose of aiding the farming and mechanical industries of the State. Our Trades Unions should cease their present useless and mischievous war against employers, and devote their energies to the establishment of coöperative industry, as the true and only legitimate remedy for labor against the impositions of capital. Their efforts should be directed to the creation and building up, instead of to the discouragement and breaking down of values.

When these changes take place in our business and monetary interests, then, and not till then, can we become a really prosperous people. Then, and not till then, can we, with propriety, send out agents to crowd emigration to this coast.

It would be a shame and a reproach to our people to undertake any special encouragement of emigration to this State at the present time, except of such as can bring with them sufficient means to make business for themselves, or take them back again in case of need. Contrary to the opinion generally promulgated by the press of this State, we say, unhesitatingly, that California is no place, at this time, for a poor man to come to. The time has gone by when a man can go into the mines and make wages with his pick and pan or rocker. Now and then a prospector makes a "strike" in the mines; but such instances are rare exceptions.

It requires money to go into the valleys or mountains and occupy land, even if such land is free. The emigrant and his family must live while his vineyard is growing, or his crops maturing; and then he must have a market for his produce. He must have capital wherewith to buy cows for his dairy or sheep and goats for his stock ranges. If he comes here poor he must find others in the business in which he wishes to engage, where he can obtain employment until he can earn the necessary money to start in the business himself.

Moreover, we want a diversified system of farming, such as will give steady employment, the year round, instead of compelling the laborer to remain idle half the year or more, during which time the surplus earnings of the busy months are entirely absorbed.

We also want small manufactories, out of which larger ones may grow. The individual who makes anything, however trifling, which society requires, benefits himself and profits the community. If he is enterprising and industrious, his business will grow. When there is a lack of individual capital let several individuals unite—coöperate; they will thereby make business for themselves and others, and we shall have more workers and fewer idlers. We are importing articles to the value of many millions, annually, which ought and might be produced here, thereby giving full employment to those already in the State, and creating a demand for labor from abroad, which would be heard farther and wider than would the call of the most industrious and clamorous "society for the encouragement of immigration" which could be devised. Such manufacture would also provide diversified labor and create a largely increased market for the product of our farms. The permanent industries of a community are always coöperative in their action, mutually building up each other and the State.

The leading merchants of this city have become rich and too careless of trade. They are too often indisposed to extend such accommodations to interior traders as can be obtained in the Atlantic States. Such action drives trade from this coast, and tends to break down and discourage small trades and mechanics at home. Our middle-men demand exorbitant profits, and are too much inclined to favor trade in imported products rather than in home-made. Our manufacturers of soap, candles, shoes, clothing, agricultural implements, glassware, etc., etc., are suffering from such a suicidal policy. Our merchants don't seem to recognize the elsewhere-accepted fact, that large business and small profits is better than small business and large profits; nor that while the former stimulates productive industry the latter hinders it.

To expect well-to-do emigrants to come hither in any considerable numbers is an absurdity. Men in comfortable circumstances are generally inclined to let well enough alone, and stay at home among their friends and kindred. Poor emigrants will not, and should not, come here, in large numbers, until we change our modes of doing business, and furnish a greater amount of diversified industry.

There is reason, however, to hope that a better day is dawning for California. The extension of local railroads; the more rapid and cheaper communication with the Eastern States and the Orient is bringing us down from our stilted position, and doing away with the old mania for large and sudden gains. The influence of the gradual incoming of steady workers; of traders with economical and more correct ideas of mercantile practice; of men of moderate means and industrious habits coming to initiate and carry on the smaller manufacturing enterprises we so much need here, is already beginning to be felt in our midst. These men are coming with habits and calculations more consistent with a permanent state of society, and with the actual needs of the State. Our own people are also becoming aware of the cause of our lack of prosperity, and are recognizing the true remedy therefor. Let us hope that the anomalous state of things which has so long existed on the Pacific coast, is now giving way to a new condition, under the influence of which California will soon take that rank in the family of States to which her unparalleled resources, climate and position on the map so fully entitles her.

* * *

The Geological Survey.—Mr. Goodyear has been sent by Professor Whitney to examine the coal beds at Mount Diablo. A party will probably start off in a week for one of the mining camps. The dearth of money in the General Fund is a serious drawback to the prosecution of the work.

Harvard University has eleven hundred and seven students, forty-nine professors and forty-two other teachers.

A Full List of Patents Issued to Pacific Coast Inventors.

[From Official Reports to DEWEY & CO., U. S. and Foreign Patent Agents, and Publishers of the Scientific Press.]

For the Week Ending April 5th.

Sulky-Plow.—John H. Cole, Vacaville, Cal.

Lifting-Jack.—Leon Paul Garcin, San Francisco, Cal., assignor to himself and John D. Hooker, same place.

Lasting-Machine.—Karl Grassau, Virginia City, Nevada.

Pencil-Holder.—Annie J. Hall, San Francisco.

Reflector for Streets.—Abraham Keefer Grim and Austin D. Moore, San Francisco.

Self-Tightening Buckle.—Matthias Marvin, Salem, Oregon.

Extension Bed.—Frederick Menzer, San Francisco.

Apparatus for Disintegrating Ores.—Almarin B. Paul, San Francisco.

Gang-Plow.—James W. Sursa, San Leandro, Cal.

Note.—Copies of U. S. and Foreign Patents furnished by Dewey & Co., in the shortest time possible (by telegraph or otherwise), at the lowest rates. All patent business for Pacific coast inventors transacted with greater security and in much less time than by any other agency.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co's Scientific Press American and Foreign Patent Agency, the following are worthy of mention:

Extension Bed.—F. Menzer, S. F., Cal. The object of this invention is to construct an improved extension bed with drawers, which is more especially useful as a bed for growing children, and where space is limited. It consists in making the bed with two sets of side rails, one set being attached to the head-board, and the other to the foot-board. The slats or supporters for the mattress are placed lengthwise and hinged together at a point, which enables a portion to stand perpendicularly against the head-board, when the bed is closed up. The mattress is also jointed, and when the bed is closed up may serve as a bolster, or may stand entirely out of the way like the bottom. Drawers are arranged at both head and foot of the bed so as to close beneath it and out of sight. The whole is a very neat and convenient article of furniture.

Metallic Wagon Standard,—J. Henry, Suisuu, Cal.—This standard is cut out of sheet or plate metal, and is bent at the sides so as to form three sides of a parallelogram, for the sake of strength. Braces extend from the top to the bolster, either being out from the same piece of metal as the standard, or being cut separate and riveted or welded to the sides. By means of side-plates and bolts the standard is attached to the bolster. The whole forms a very simple, light, strong and cheap contrivance, which is capable of standing great strains without injury.

Beverage.—L. F. Lastreto, S. F., Cal. The nature of this invention is to provide an improved beverage to be known as "Choca" which shall be a substitute for coffee, chocolate and beverages of that class, and which, while containing all the properties of either, as a stimulant, shall have an additional tonic effect, which renders it valuable for invalids and enables those to use it who cannot drink the others.

* * *

Mr. Vincent's lectures on Cromwell, and the times of Queen Elizabeth, this week, were rare treats. The lecturer's manner is very happy, his language fluent and well chosen, and his subject matter excellent. His lectures were well attended, and his audience were kept in close attention throughout. We are happy to have such as Mr. V. visit our city. They get the people into the habit of going where they can get good instruction. Would that we might rival Boston in the way of attending lectures.

* * *

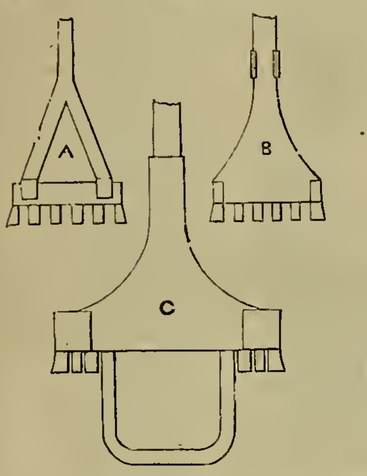
We lately had the pleasure of seeing a beautiful design of the building for the California Silk Manufacturing Co. at the office of A. H. Jordan, architect, No. 430 Montgomery street. The building is to be 50 by 230 feet.

Boring Large Shafts.

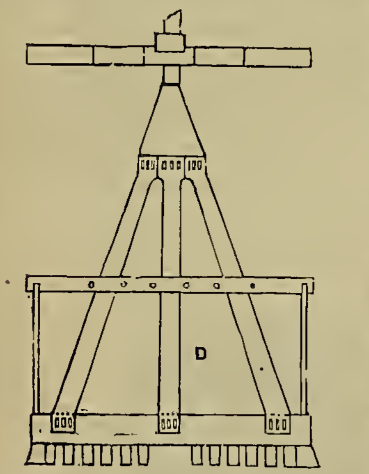
In the report on mining of the U. S. Commissioners to the Paris Exposition, the description of the boring tools and apparatus exhibited is very interesting, and indicates a new era in the art of boring. Formerly, pits sunk by such means were of small size, diameters of artesian wells not exceeding 12 inches. But French engineers have so improved on the methods, that, for instance, there is a well at Passy, near Paris, with a diameter of over 3¼ feet at the top, and 2¼ feet at the bottom, and it is known to be possible to sink shafts over 13 feet in diameter through strata of great hardness.

Shafts Sunk at L'Hopital.

As an example of what has been done, we quote from the description of the two shafts sunk by Mr. Kind and Chaudron, at L'Hopital, department of the Moselle, in the basin of Saarbruck. The coal occurs under strata composed of the sandstone of the Vosges, and the new red sandstone. These are at first very silicious and full of fissures, than becomes argillaceous, and near the coal are impermeable to water. In the new methods, called *a niveau plein*, the water is *not pumped out* of the shaft during the operation, thus saving much trouble and expense.



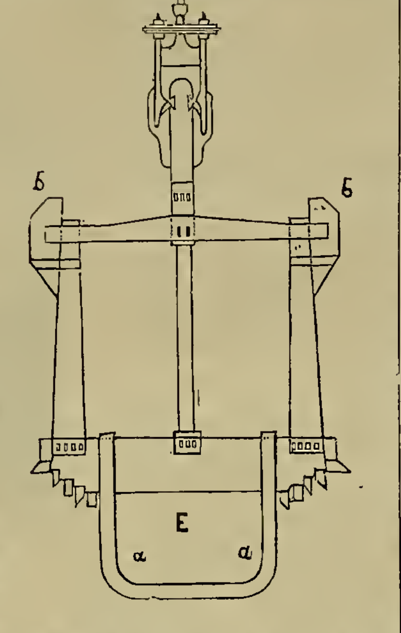
Of the two pits, one had diameters of 8.4 and 6 feet, and the other 13½ and 11 feet at the top and bottom respectively. Three engines were used, one for hoisting and lowering the boring tools, and lowering the tubbing or lining of the shaft, one for working the borer, and one for running a pump for hot and cold water, being indispensable for supplying the boiler as the others worked irregularly.



Boring the Pits.

Shaft No. 1.—A preparatory pit was sunk to a depth of 70 feet, and lined with masonry, on which rested the derrick, etc. The sinking was then accomplished by first driving a central pit of 4½ feet, and then enlarging this to 7½ feet, the *debris* of the enlargement falling into this first pit. For boring, the trepan, A, was first used. It weighed 4,587 pounds, and had teeth of cast steel or of iron faced with steel. The distance between the outer edge of the outer teeth was 4½ feet, and the fall 9.8 feet. Its daily progress through the upper sandstone was first 2.9, than 1.7, and then 0.9 feet, but at a depth of 443 feet, in strongly aggregated silicious red sandstone, this was only 0.36 feet, and three ruptures of the stem led to the substitution of the form, B, weighing 8,488 pounds, which progressed daily 1.3 feet, showing that heavy trepans are best for hard strata.

For enlarging the pit, a trepan similar to A, and weighing 8,756 pounds, was used. On account of the frequent breaking of the teeth it was lifted only 8 inches. Its daily progress was from 3.6 feet to 0.6 feet at the last, when its weight was found insufficient on reaching hard sandstone, and the form, C, was finally used. This weighed 17,600 pounds, was 8 1-5 feet in diameter, and made a daily progress of one foot.



The diameter of the pit was, at the surface, 8 4 feet; 440 feet down, 8 feet; 518 feet down, 7.4 feet. Then the little pit continued 23 feet further, and a circular curbing was fixed to receive the base of the tubbing. The work of sinking the shaft lasted 28½ months. The central pit required 346 days of actual work, and the enlargement, 320½ days. The mean daily progress of the small pit was 1.3 feet, of the enlargement about 1.4 feet.

Shaft No. 2.—The preliminary shaft was 69 feet deep, and lined with masonry. The central shaft was made by means of the trepan, A, to a depth of 485½ feet, at a daily average varying from 2.9 to 0.75 feet. This was then enlarged to 13½ feet by a larger two-bladed trepan (which, however, proved too light) to a depth of 397 feet. This first period lasted 448½ days, the small trepan being stopped only one day, and the larger, 22½ days.

Then the central shaft, 4½ feet in diameter, was carried down to a depth of 560 feet in 42 additional days with B; enlarged to 8.2 feet to a depth of 538 feet in 90 days with D; and still further enlarged to 13.4 feet in diameter to a depth of 512 feet in 173 days with E, which was, however, rather too weak for hard rock. The tubbing reached 521½ feet from the surface, and the work lasted 29½ months.

The rods used were 59 feet long, and 2.8 square inches in section. The jars are similar, at least, to those which have been described in previous works.

The stoppages and breakages of the weak parts of these trepans led Mr. Kind to build the form E. Here *a* is the guide which enters the central pit, and, with the guides, *b b*, keeps the enlarging tool vertical.

[CONCLUDED NEXT WEEK.]

A NEW POWDER, manufactured by the California Powder company, will be noticed more fully next week.

Our Home Industries.

Asphaltum Water, Drain and Gas Pipes.

Among the natural resources of California must be included its asphaltum deposits, which are quite numerous. This article has been used for several purposes, as roofing, pavements, etc., and as our State grows, and manufactures increase, its use will undoubtedly be extended, and the proprietors of the lands holding this article will find it ever in greater demand. One of the uses to which it has been put of late is in the manufacture of water pipes, and there is already a place in this city where these are made. Mr. J. L. Murphy has been at work some two or three years perfecting his processes, and is now able to produce a superior article, which is at once strong, durable and cheap. Asphaltum has been used for the various kinds of pipes for some time in Europe, and its advantages have been shown to be such that it is coming continually into more extended use.

Preparing the Asphaltum.

The raw article is taken from the neighborhood of Gilroy. As, however, in its natural state, it contains considerable earthy matter, it is necessary to first free it from this. The clarification is effected by heating it in kettles until the liquid mass is thin enough to allow the sediment to fall. When this has settled, the purer part is dipped out and permitted to cool and harden. As in the process some of the lighter oils are driven off, and the mass then would form too hard a substance, a little coal tar is added to soften it. The asphaltum is then shipped to San Francisco in blocks, which are broken up into small pieces and melted in large tanks set over a fire-place.

Forming the Pipes.

The liquid asphaltum is then put into a semi-cylindrical trough, where it is kept hot by a fire below. In this trough revolve two rollers, which are placed side by side, so as to be half submerged in the liquid. Above there is a roller or mandrel of the size of the interior diameter of the pipe to be made. This mandrel is previously covered with paper. In front of the trough are spools on which the burlaps used is rolled. It is proposed to have this cloth made in strips of a thickness equal to the length of the pipe (twelve feet). One end of the burlaps is passed through the asphaltum, around the under side of the rollers, and placed on the mandrel, where it adheres, as it is now saturated with asphaltum. Then the mandrel is dropped so that it rests on the rollers, and then all are revolved until the pipe has been formed of the required thickness. As the mandrel rests on the rollers, the pipe is made uniform. When it is of the proper size the cloth is cut, and the pipes thus formed of saturated burlaps is removed from the asphaltum by raising the mandrel and allowing it to cool. It is then revolved again in the hot liquid a few times, raised, removed from the mandrel—a process rendered easy by the paper first placed around this—and then rolled by hand on a table in coke-powder. It is then rolled on the table-top (without coke-dust) to get a proper surface, and the ends are cut so as to have a length of just twelve feet.

Glazing and Jointing.

The inside of the pipes is now glazed, to preserve a smooth surface, that there may be as little friction as possible for the water flowing through. This is effected by closing one end of the pipe with paper—which article is taken principally on account of its cheapness—a few dipperfuls of melted asphaltum poured into the other end, and the pipe rolled to and fro to cover the whole inside with a layer of the liquid. The excess of asphaltum is poured off, and, in this simple way a good glazed interior is obtained.

The pipes are jointed when laid in position. The ends of two lengths being brought together, a strip of burlaps, saturated in melted asphaltum, is wrapped around the joints. Then one-half of a cement collar, specially invented by Mr. Murphy, and which is moulded in two parts, is placed under the joint, and the spaces filled with melted asphaltum. The other half of the collar is then put on, and thus we get a solid joint, as strong as, if not stronger, than the rest of the pipe, as proved by hydraulic tests. So simple is the operation that one man can joint ten to twelve hundred feet of 4-inch pipe in ten hours.

Strength of Pipe, Etc.

All required sizes of pipe are made at this establishment. They are much stronger than one might think from merely seeing them, and Mr. Murphy asserts that he can easily make, for example, a 10-inch pipe which will stand a pressure of 500 pounds to the square inch. Repeated hydraulic tests have proved the strength of the pipe and of the coupling used. Water pipes of this manufacture were laid throughout Petaluma last June, and a mile of it has just been sent to Colusa for the water works there.

The great advantages claimed for this pipe are the small weight and consequent ease of handling and laying it, the insured purity of the water, its durability and its small expense. It costs, inclusive of couplings, a sum per inch equal to the product (in cents) of ten into the diameter of the pipe. Thus 2-inch pipe costs twenty cents per inch, 4-inch pipe forty cents, and so on; which is very cheap compared with iron. The manufactory, we should state, is situated on King street; and Mr. Murphy intends adding the manufacture of gas pipes in a short time.

SILK AND TEA CULTURE and other Asiatic Industries adapted to the Soil and Climate of California. By T. A. Kendo. San Francisco: A. Roman & Co., Publishers.

The above is the title of a very neat little volume of seventy-four pages, wherein the subject of silk-growing is quite carefully considered in relation to its introduction into California and its practice in Japan; the character of the soil and location required for the mulberry tree; the preparation and planting of the seed; feeding the worms; gathering the cocoons, and all other matters essential to the establishment of such business.

The culture of tea is also discussed at considerable length, and the adaptability of such culture to California conditions of soil and climate is considered; the conclusion being that this State is well adapted to such industry. Brief mention is also made of the vegetable wax and lacquer tree of Japan; of the Japanese chestnut and of the persimmon tree and fruit. The volume contains much information, briefly and clearly expressed, upon subjects in regard to which much attention is just now being attracted, and about which just the information here given is desired. Price, one dollar.

FIRE IN THE AMADOR MINE.—Last Monday smoke was discovered at the 844-foot level in the north shaft of the celebrated Amador mine. Efforts made to extinguish it with water carried down from the surface proved ineffectual, and the men were called up from their work. Then all the shafts were covered and water poured down in large amounts. The smoke finally decreased and had nearly ceased at six o'clock in the evening. The mine was kept closed tightly all night. The fire is now believed to be extinguished and the shaft was being explored at last accounts.

NEW STEAM COFFEE MILLS.—Descalzo, Lastreto & Co. have recently established a new steam mill, at 526 Washington street, for the preparation of chocolate and coffee, in all the various ways in which those articles are put up for table use. They are also the sole manufacturers in California, of the world-renowned "Cafe des Gourmets," by the Corcelet process.

MARAVILLA COCOA.—*For Breakfast.*—The *Globe* says: "Various importers and manufacturers have attempted to attain a reputation for their prepared Cocoas, but we doubt whether any thorough success has been achieved until Messrs. Taylor Brothers discovered the extraordinary qualities of 'Maravilla' Cocoa. Adapting their perfect system of preparation to this finest of all species of the Theobroma they have produced an article which supersedes every other Cocoa in the market. Entire solubility, a delicate aroma, and a rare concentration of the purest elements of nutrition, distinguish the Maravilla Cocoa above all others. For homœpaths and invalids we could not recommend a more agreeable or valuable beverage." Sold in packets only by all Grocers, of whom also may be had Taylor Brothers Original Homœopathic Cocoa and Soluble Chocolate. Steam Mills—Brick Lane, London. 5v20-1y

The Celebrated Studebaker Wagon,

Manufactured by STUDEBAKER BROS. MANUFACTURING CO., South Bend, Indiana. WAGON DEALERS, there are nine reasons why you should buy the above Wagon:

FIRST.—They are made of the best selected INDIANA TIMBER, thoroughly seasoned under cover. SECOND—They are made by experienced mechanics. THIRD—The lightest running and most durable Wagon in the market. FOURTH—Their Thimble Skeins never break, while all others do. FIFTH—Most uniform and best proportioned Wagon in the market; any part of one will fit another, while other makes will not. SIXTH—The only Wagon in which the SLOPE SHOULDER SPOKE is used; hence they have the best Wheel, which is actually the foundation of the Wagon, and should be carefully examined by persons buying. SEVENTH—They are sold only by responsible parties, and every Wagon is warranted to give entire satisfaction. EIGHTH—Because Teamsters will tell you they are the best Wagons, for all purposes, on the road. NINTH—Last, but not least, Studebaker Brothers are practical men, attend to their business personalty, and do not entrust it entirely to foremen, as is generally the case in large factories; hence the superiority of their work over all others.

LEA & PERRINS'

CELEBRATED

Worcestershire Sauce.

CAUTION AGAINST FRAUD.

Declared by Connoisseurs to be the only good SAUCE. The success of this most delicious and unrivalled Condiment having caused certain dealers to apply the name "Worcestershire Sauce" to their own inferior compounds, the public is hereby informed that the only way to secure the genuine is to ASK FOR LEA & PERRINS' SAUCE, and see that their names are upon the wrapper, labels, stopper and bottle.

Some of the foreign markets having been supplied with a spurious Worcestershire Sauce, upon the wrapper and labels of which the names of Lea and Perrins have been forged, L. and P. give notice that they have furnished their correspondents with power of attorney to take instant proceedings against manufacturers and vendors of such, or any other imitations by which their right may be infringed.

Ask for LEA & PERRINS' Sauce and see name on wrapper, label, bottle and stopper.

Wholesale and for export by the Proprietors, Worcester; Crosse and Blackwell, London, &c., &c., and by Grocers and Oilmen universally. Agents, CROSS & CO., San Francisco. 1v20-1yeow

DR. ABORN,

Oculist, Aurist,

AND

CATARRH, THROAT

AND

Lung Physician.

No. 22 KEARNY STREET,

SAN FRANCISCO, CAL.

Testimonials from Well-known Citizens of California as evidence of his success.

Card from Charles N. Fox, Esq., of the firm of Campbell, Fox & Campbell, Attorneys, 528 California Street.

I have for many months suffered from Catarrh, accompanied with unpleasant sensations and sounds in the ears. Recently I found my hearing impaired, and at once applied to Dr. Aborn, No. 22 Kearny street, San Francisco. He improved my hearing almost instantaneously, and now, after being under his care six days only, I feel as if entirely cured, and my hearing is restored. CHARLES N. FOX.
San Francisco (Cal.), Jan, 10, 1870.

Card from S. O. Houghton, Esq., Attorney at Law.

I have been afflicted with severe nasal Catarrh for two years, which a few months since extended to my throat, producing a distressing cough, and seriously impairing my health generally. I have been under treatment by Dr. Aborn, at 22 Kearny street, San Francisco, for about three weeks, and have been already greatly relieved—my cough has almost disappeared and my health greatly improved. By one application, Dr. Aborn relieved me of a very severe neuralgic pain, and with four applications it was entirely cured. S. O. HOUGHTON.
San Jose (Cal,), Nov. 22, 1869.

From Hon. Jas. A. Johnson, M. C., California.

TO WHOM IT MAY CONCERN.—Having been a sufferer with Catarrh and a severe bronchial affection for more than seven years, and having found great relief by submitting myself to Dr. Aborn's treatment for a few days only, I take pleasure in saying Dr. Aborn, with his new and improved instruments for local applications to the lungs, air passages, eyes and ears, should encourage all who are affected in those parts to cherish a lively hope that they may find quick and permanent relief. Very truly, JAMES A. JOHNSON, M. C., California.

A Wonderful Cure.

Having been afflicted for over twenty years with a disease in the left nostril, which has been called by different names—cancer, scrofula and ozena—different physicians have tried their skill in attempting its cure, but without success. It has rendered me incapable of labor for the last two years. Since the beginning of June last I have been in the Sacramento hospital reduced to a mere skeleton. On the 23d of November I left the hospital, and since the 26th have been under the treatment of Dr. Aborn in this city, and the disease is already nearly cured, and my strength and general health very much improved, and I have full confidence of a perfect cure. Already I have gained many pounds in weight, and look and feel like another person. The success of Dr. Aborn's treatment in my case should be sufficient to encourage all who have chronic diseases to make another trial for that good prize—health.

WILLIAM BEARDSLEE.
Pacific House, San Francisco, Dec. 13, 1869.

Another Remarkable Cure.

For the benefit of the afflicted and as an act of justice to the skill of Dr. Aborn, I make the following statement: For about two years I was seriously afflicted with a bronchial affection. I had a distressing cough, difficulty of breathing, expectoration, night sweats, and was losing flesh very rapidly. I was treated by five physicians without any benefit, but continued to grow worse, and was finally advised by them to leave the city, as in their opinions I could not be cured in this climate; but my business relations were such as to preclude a change of climate, although my health was declining so fast that I could not have lived long without relief. Two months ago, when Dr. Aborn arrived, I read his publications and the testimonials of his remarkable cures, which led me to believe that there must be merit in his treatment. So I placed myself under his care, and it is with great pleasure that I am able to say that he has cured me of those distressing and dangerous bronchial affections; also, the night sweats, cough, etc. I was unable to attend to business since April last, until after being under Dr. Aborn's treatment for one week. My improvement was so rapid that in one week's time I was able to resume my business, and I have continued to gain ever since so rapidly that even my friends are surprised at the remarkable results of his treatment.

VINCENT MONATTI,
Corner of Dupont and Green streets.
San Francisco, Dec. 25, 1869 7v20-3m

GIANT CEMENT.
GIANT CEMENT.

A most extraordinary and universally needed article for mending Furniture, Crockery, Glassware, Marble, Meerschaum Pipes, Ornaments, etc.; also splicing Leather Belting and patching Boots and Shoes. This Cement possesses extraordinary merit, and is in every way a first-class article. Every can is its own testimonial. eport of Samuel S. Fisher, Commissioner of Patents.—1869.

[CONTINUED FROM PAGE 244.]

Annual Report.

Since the year 1843, a report has been bliched annually, containing an alphatical index of inventors, an index of the bject of invention, a list of expired patte, and the claims of the patents granted ring the year. In the year 1853, and nce, small engraved copies of a portion the drawings have been added to explain e claims; and of late years, it has been stomary to add a very brief abstract of e specifications, comprised, usually, in t more than four or five lines. The rert was a pamphlet of a few pages in 43; in 1867 it had swelled to four large lumes. The expense of producing it is w over two hundred thousand dollars r annum. It is true that this amount s not been paid out of the patent fund; e report has been published as a docuent by Congress. Nevertheless, as a porn of the expense of preparing it is borne the office, it is proper to refer to it here. I doubt if a sufficient advantage accrues the country from the publication of s report, to justify the expense. Its lk is such that it cannot be published til from eighteen months to two years er the expiration of the year in which e patents are issued. The claims are in st instances unintelligible, without the ecifications, even with the aid of the abacts and engravings; while the engravgs themselves are not and cannot be cop of all the drawings, or figures accomnying the patent. A large number of ents have more than one figure, somees twenty. In the printed reports, e or at most two, are given, for want of ace to do better. Such mere sketches of patents and drawings, in many cases, do re harm than good. They mislead the blic, instead of instructing it. It is true t it is desirable for some persons to ow, from time to time, what patents are nted; but the number of such persons limited, and the knowledge, to be valble to them, must be furnished simultausly with the issue of the patents. This ormation has, until a year ago, been pplies by certain mechanical journals. ey published weekly lists of claims, un the issue increased to such an extent as make it impossible for them to continue practice. The office then attempted to pply this want. A weekly list of claims has n published, and furnished to subscrip, since January, 1869; at the rate of five lars per annum. To this has since been led a pamphlet containing the Commisner's decision, which is issued at intere of from one to two months. This r these claims are being stereotyped, so t, at the close of the year, they may, h proper indexes, constitute the annual ort, without the abstracts or drawings. Congress should desire to strike off cop of these for gratuitous contribution, it ld be done at small expense, scarcely eeding one dollar per volume, whereas present reports cost twelve dollars and alf per set. It is submitted, however, t if these lists of claims are of value to y one, they are worth the small price ich the office now asks for them.

n addition to these weekly lists, I prose, as a substitute for the annual report now published, that a sufficient number copies of each entire specification and wings be printed in full, and that one l set be deposited in the capital of each te, and in each large city. This would nish nearly all the information to be ained by a visit to the Patent Office, and uld save inventors many journeys to ashington. It would enable counsel a distance to examine references, and to tain information, now practically inacsible, without a personal visit, or the ployment of the resident counsel. To Pacific coast, the west, south, and far rtheast, such collections would be inuable. Each annual set would be comsed in about fifty-two volumes. A suffint number of them for the purpose ted, and for office use, could be furnished, an annual cost not exceeding one bund thousand dollars, or about one half of e cost of the present annual report. To ke such a collection complete, the back awings and specifications of patents aldy issued should be published also. r this purpose, the balance already nding to the credit of the patent fund is bably sufficient.

Statutes of Limitations

The courts have decided that no statute ists limiting the time within which acns may be brought for the infringement letters patent. The action on the case the several States is variously limited to one, three, five, and six years. I submit that a limitation of five years, after the expiration of the patent, would be a proper provision.

Some provision is also needed limiting the time during which applications shall be permitted to lie in the Patent Office, after action, before the next step by way of appeal or amendment is taken. Much injury to the business of the country is likely to result from the construction lately given to the law by the Judge of the Supreme Court of this district, by inflicting patents upon the nation for inventions which have long been in public use. This is, in effect, to create a monopoly, instead of affording an encouragement to inventors.

There are hundreds of these cases in the office, many of which are being bought up on speculation, and vigorously pressed for issue. One of these, lately filed, was withdrawn in 1851, and has now been re-filed, after a lapse of nineteen years, when the substance of the invention which it seeks to monopolize has gone into use in nearly every form in which a well known agricultural implement is now manufactured.

[TO BE CONTINUED.]

Musical Education.—The San Francisco Musical Institute is doing a good work in a very quiet, unpretending manner. Already there are over a hundred pupils, and the orchestra and chorus classes are held weekly, affording students admirable advantages which can not be obtained in any other way. This opportunity of practicing in orchestral and chamber music, cannot be too highly appreciated, and is the perfection of instruction. Pupils have, moreover, opportunities of hearing the performances of skillful musicians, and thus seeing the particular points in which they excel. The whole system of the Institute is one which has been proved to be excellent, and is founded on those of the best schools of Europe and the East.

The first bar of California tin has been presented to the Society of Pioneers. It is eight inches long, four inches wide, and two inches thick; contains, by assay, 97.09 per cent. metallic tin, with some tungsten and traces of antimony, arsenic, sulphur and iron. On one side, there is engraved the following inscription: "First bar of tin ever produced in the United States from native ore; taken from the San Jacinto Tin Mine, San Bernardino county, California. Presented to the Society of California Pioneers, by O. P. Sutton, April, 1870.

City Foundry.—Messrs. Clerc & Co. have been quite busy all winter. They are now engaged on machinery for the La Grande and Occidental laundries and the laundry of the Grand Hotel; also, on machinery for the Franco-Italian Chocolate Factory. They are making also large punching machines for boiler work, jigsaws, castings for agricultural machinery, a new style of coffee-roaster, small three to five horse-power steam engines, and several other items.

Sportsmen desiring a superior gun or fishing tackle or any such apparatus would do well to examine the fine stock of Messrs. Barton & Rutter, 609 Clay street. This firm is, moreover, the sole agency for Alexander's pocket cutlery, which has attained such celebrity on this coast and elsewhere. As the house imports directly from the manufacturies and keeps none but the best goods, they are able to furnish an excellent, and at the same time comparatively cheap article.

Testing Ores.—Messrs. Morris & White, No. 30 Fremont street, have lately enlarged their works and have built a reverberatory furnace. They are now ready to test ore by amalgamation or chlorination and lixiviation, or will purchase. They have recently worked very successfully several large amounts of amalgamation tailings, and also quantities of crude ore for parties desirous of testing their mines and ascertaining the best manner of working their ores.

New Incorporations.

The following have filed certificates of incorporation with the County Clerk, San Francisco:

Mountain City M. Co.—April 4. Capital stock, $1,600,000; 16,000 shares, $100 each. Trustees: Moses A. Meader, Isaac F. Davis and Benjamin F. Page.

City Gas Co.—San Francisco. April 4. Capital stock. $10,000,000; $10,000 shares, $100 each. Trustees: J. B. Haggin, S. F. Butterworth, N. Luning, Lloyd Tevis and Thomas Bell.

The following have been recorded in the Secretary of State's office, Sacramento:

Bay Spring Water Co.—Alameda county. April 4. Capital stock, $50,000; 500 shares. Trustees: George W. Cook, Ira Marden and Charles W. Cook.

The Kimball Wagon and Carriage Company, and the California Powder Company have established agencies at Corinne for the supply of Utah, Montana and Idaho with their goods.

The Boy of the Period Journal, published at Washington, D. C., has been received. It is a remarkably smart effort on the part of Young America.

Choice Advertising

Pays the best. If you advertise in a newspaper, choose one of good and substantial character which is most patronized by the class you wish to reach. If you advertise by display cards, put them where they will be most seen by the best class of patrons.

We believe there is no other single conveyance from San Francisco that takes so many different passengers in each twenty-four hours as the steamer New World on the Vallejo route—her passengers go to Solana, Napa, Sonoma, Mendocino, Lake, Yolo, Yuba, and all the middle and northern mining counties of California and the State of Nevada. In fact, the best part of the travel northward and eastward goes by this short, popular and safe route.

This steamer makes two double trips, carrying four loads of passengers every week day, besides making regular trips on Sunday. The passengers have pleasant leisure aboard, such as to make a respectful advertisement placed before them available.

Observing this remarkable opportunity for effective advertising, Mr. A. Kronberg, the gentlemanly news agent on the route, has furnished a fine advertising frame, accommodating a number of choice advertising placards, which he rents at a reasonable rate per month to first class firms, who are the most likely to appreciate a "live" advertisement. He has the exclusive privilege on the New World—a good thing for himself and advertisers. *

A Valuable Book for Inventors and Artisans.—Dewey & Co., publishers of the Scientific Press and Patent Agents, have just issued a neat little volume of over five hundred well executed cuts of the principal mechanical movements known. These useful representations of the various appliances of power are printed side by side with explanatory notes, which makes the subject clear to every reader. Such a book should be in the hands of every mechanic, and form part of every public school library. It is a handy book, and cheap enough for every farm, shop and factory. Sent to any address from the Scientific Press office, postpaid, for $1.—*New Age.*

Treatment of Rebellious Silver Ores, by Charles H. Aaron—a pamphlet of eight pages, of concise reading, of practical value to parties interested in the subject. Printed and sold by Dewey & Co., at this office, for 25 cents, post paid.

The Portable Gas-Burner at P. J. Phillips & Co's, 650 Market street, below Kearny, is the only burner that does not smoke or smell, and that can be regulated to give any quantity of light desired. Call and see. County Right for sale. *

Business Fortunes are often made easily, quickly and legitimately by Patent Rights. We advise both sellers and purchasers to patronize reliable agents only. Weister & Co., patent brokers, No. 314 Bush street, San Francisco, are one of the most honest, reliable firms in the United States. *

Mason's Bread of Life, for Dyspeptics, Coughs, Colds, Asthma, Catarrh, Hoarseness, Bronchitis and Sore Throat. Price, 25 cents per box. These lozenges are free from all dangerous properties. Compounded and put up by Dr. J. H. Mason, 750 Howard st. 16v20-3m

Photography.—For Cabinet Photographs, or Enameled Cards, of the very best quality, you must go to the NEW YORK GALLERY, Nos. 25 and 27 Third street, San Francisco. Every picture warranted to give satisfaction.
10v18 6m B. F. Howland.

Postponement.—The sale of the above stock is hereby postponed until Monday, April 25th, 1870. By order of the Board of Trustees.

ap16 EDWARD C. LOVELL, Secretary.

Office of the Placer Gold Mining and Canal

Company.—Location of Works: Township No. Six (6), County of Placer, State of California.

Notice is hereby given, that at a meeting of the Trustees of said Company, held on the ninth day of April, 1870, an assessment (No. 1) of two dollars ($2) per share was levied upon the capital stock of said Company, payable immediately, in United States gold coin, to the Secretary, at the office of the Company, No. 802 Howard street, San Francisco, California.

Any stock upon which said assessment shall remain unpaid on Friday, the twentieth day of May, 1870, shall be deemed delinquent, and will be duly advertised for sale at public auction, and unless payment shall be made before, will be sold on Friday, the tenth day of June, 1870, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Trustees.

C. S. HALEY, Secretary.

Office of Company, 802 Howard street, San Francisco, Cal. Office hours: 6 to 8 P. M. apr16

Mining Notices--Continued.

Alban Gold and Silver Mining Company.—

Location of Works: Virginia City, State of Nevada.

Notice is hereby given, that at a meeting of the Board of Trustees of said Company, held on the twenty-first day of March, 1870, an assessment of five (5) cents per share was levied upon the capital stock of said Company, payable immediately, in United States gold coin, to the Secretary, or to Geo. Bordwell, Esq., President of said Company, at his office, No. 432 Montgomery street, San Francisco, Cal.

Any stock upon which said assessment shall remain unpaid on Monday, the twenty-fifth day of April, 1870, shall be deemed delinquent, and will be duly advertised for sale at public auction, and unless payment shall be made before, will be sold on Saturday, the fourteenth day of May, 1870, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Trustees.

WM. B. SMITH, Secretary.

Office, 432 Montgomery street, San Francisco. m26

D. A. JENNINGS, Secretary.

Office, 419 California street, San Francisco, California.

WIESTER & CO.,

PATENT BROKERS,

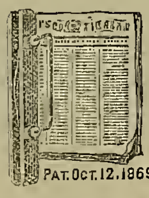
314 BUSH STREET,

SAN FRANCISCO.

Patents Bought and Sold on Commission.

For the benefit of those who live at a distance from he city, we give below a brief description of a few of the valuable Patents which we have in our office. It may be well to state here that no Patent is received by us for negotiation until it is first endorsed by reliable experts, to whom each is subjected for acceptance or rejection. We treat all patents alike, recommending only where true merit is found in the invention.

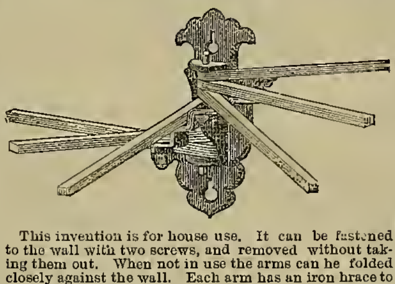
BURGESS' PATENT PAPER FILE.



PAT. OCT. 12, 1869

This is a recent patent, and one of no ordinary merit. It is light and complete, yet costs but little. In all file-holders before presented to the public, the papers are very liable to tear, or else the method of inserting them requires too much time and trouble. This device is easily adjusted, is not liable to tear the paper, nor let it loose. This patent is also used in combination with covers for forming music folios. Musicians who have seen it, speak in the highest terms of its value. No person can fully appreciate the Paper File or Music Folio without seeing one. The Legislature of California has taken 350, and we feel sure that hotels, private families, societies, legislatures, and reading rooms of every description, will have them as soon as they can be found in the market. Here is an opportunity for a manufacturing establishment to start a paying business on small capital. The Right to all the States and Territories west of the Rocky Mountains will be sold together and sold cheap. Manufacturers and others are invited to call at our office and examine this useful California invention.

HOTCHKISS' CLOTHES DRYER.



This invention is for house use. It can be fastened to the wall with two screws, and removed without taking them out. When not in use the arms can be folded closely against the wall. Each arm has an iron brace to support it. This is really a "good thing in a family." County or State rights for this will be sold very low. Full particulars given on application.

A neat and convenient CUPBOARD LATCH, that answers equally well for single or double doors. It is suitable for Wardrobes, Wash-stands, Cupboards, etc.

A LOCAL AGENT wanted in every town n the Pacific coast to sell patent goods

The California Powder Works

No. 314 CALIFORNIA STREET,

SAN FRANCISCO.

Manufacturers and have constantly on hand

SPORTING,

MINING,

And BLASTING

POWDER,

Of SUPERIOR QUALITY, FRESH FROM THE MILLS, It being constantly received and transported into the interior, is delivered to the consumer within a few days of the time of its manufacture, and is in every way superior to any other Powder in Market.

We have been awarded successively

Three Gold Medals

By the MECHANICS' INSTITUTE and the STATE AGRICULTURAL SOCIETY for the superiority of our products over all others.

We also call attention to our

HERCULES POWDER,

Which combines all the force of other strong explosives now in use, and the lifting force of the BEST BLASTING POWDER, thus making it vastly superior to any other compound now in use.

A circular containing a full description of this Powder can be obtained on application to our Office.

16v20-3m JOHN F. LOHSE, Secretary.

The Equalizing Institute.

SOMETHING NEW.

THE EQUALIZER,

A GUIDE TO HEALTH.

Cures all Chronic Diseases BY VACUUM.

This treatment causes a thorough circulation of the blood throughout the system, creates new life, and reinstates perfect health. The following diseases can be cured by the above system: Paralysis, Nervous Debility, Neuralgia, Dyspepsia, Asthma, Curvature of the Spine, and other Spinal affections, Sciatica, Palsy, St. Vitus' Dance and Derangement of the Mind, and many other ailments, for particulars of which see our circular.

THE GUIDE TO HEALTH.

TESTIMONIALS.—P. Windsor, having suffered severely from four sun strokes, and in the last two years from four strokes of Paralysis and loss of speech, had recourse to the Equalizer as a treatment for same, and by means of the Equalizer was perfectly cured in the astonishing short period of four months; and as proof of the above, he can be seen at the Equalizing Institute, 650 Howard street, San Francisco.

SAN FRANCISCO, April 5, 1870.

Sunday being the Sabbath Day,

THE EQUALIZER

Will be devoted to the treatment of all chronic diseases, exclusively to the poor, between the hours of nine and four o'clock, (not including paupers), free of all charges.

PROPRIETOR EQUALIZING INSTITUTE,
16v20-qy 650 Howard Street.

B. M. HARTSHORNE,
13v12 President.

THE large majority of United States and Foreign Patents granted to inventors on the Pacific coast during the past few years, have been obtained through the agency of DEWEY & Co., publishers of the SCIENTIFIC PRESS. Established in the year 1860, we have an extensive patent library, with full record of cases on this coast, and can give the best and most reliable advice as to the patentability of new inventions.

TO MILLMEN.

FOR SALE CHEAP.—A 10-stamp mill complete; engine about 35 horse-power; cylinder 12-inch bore and 30-inch stroke; boiler 16 feet long and 48 inch diameter; weight of stamps complete, 650 pounds. The whole is as good as new; has only been running four months. Will sell either engine or battery separate, and deliver it on the railroad at Auburn if required. For particulars apply to W. NAGEL, 702 Bush street, San Francisco, or to MOUNTAIN CO., Forest Hill, Placer county. 16v20-3m

NOTICE.

HYDRAULIC HOSE MANUFACTORY.

Hose made to stand any pressure—from 100 to 300 foot fall. Miners are invited to call and examine my work. Tents, Awnings, Specie and Ore Bags made to order, and cheaper than any other factory. A share of patronage is solicited from my friends. [16v20-3m] S. HOWARD, 424 Davis st.

LOST.

Between Market street and the corner of Clay and Montgomery streets, a linen tracing of mechanical drawings representing an amalgamating pan. The finder will be rewarded with one year's subscription to the SCIENTIFIC PRESS—the most valuable illustrated weekly on the Pacific coast—by leaving the drawings at 414 Clay street,

USE
DR. S. GIRARD SMITH'S
ARAMIRACULAS
— FOR —
RHEUMATISM, GOUT AND NEURALGIA
CURES GUARANTEED.
Has cured Thousands. Has never been known
One bottle will relieve you.
OFFICE, No. 621 KEARNY STREET.

Agents Wanted in every City and Town.—Terms Liberal.
Dr. S. Girard Smith, 621 *Kearny street.*—Dear Sir It would be hard for me to say how much I thank you for the benefit your ARAMIRACULAS has conferred on me in curing my RHEUMATISM. I was confined to my bed when I first commenced to take your medicine, and after using ONE BOTTLE I am now able to work as well as before. If you know anything about having that afflictive complaint, you must know how good it is to be cured. I will state to those who may not believe in your medicine, that they can be convinced by referring them to me. Very respectfully, yours,
ENON HARRIS,
Everard's Auction Rooms, 527 Kearny street.
Statement of an old and well-known Physician who has practiced extensively in Europe and America.
We must admit that the many systems of medicine by which we have attempted to heal the human body, and rid it of disease, from the science of ALLOPATHY down to HYDROPATHY, how little they have succeeded, time has abundantly shown by their number of failures. In the cure of RHEUMATISM, GOUT and NEURALGIA, Dr. S. Girsrd Smith has laid aside the old way and adopted a system, so simple, that I must admit, is so natural and direct, that it recommends itself to all who are suffering with the above diseases. And it challenges and defies all the old methods of treatment. Although I have been educated through a regular course, and graduated in Europe, I must acknowledge the right, and also give due credit for personal benefit received by the new system as practiced by DR. S. GIRARD SMITH, which induces me to bear this testimony to its merits, for the benefit of suffering humanity.
A. M. HOFFMAN, M. D.,
11v20-3m New Orleans.

Ayer's
Hair Vigor,
For restoring Gray Hair to its natural Vitality and Color.

A dressing which is at once agreeable, healthy, and effectual for preserving the hair. *Faded or gray hair is soon restored to its original color with the gloss and freshness of youth.* Thin hair is thickened, falling hair checked, and baldness often, though not always, cured by its use. Nothing can restore the hair where the follicles are destroyed, or the glands atrophied and decayed. But such as remain can be saved for usefulness by this application. Instead of fouling the hair with a pasty sediment, it will keep it clean and vigorous. Its occasional use will prevent the hair from turning gray or falling off, and consequently prevent baldness. Free from those deleterious substances which make some preparations dangerous and injurious to the hair, the Vigor can only benefit but not harm it. If wanted merely for a
HAIR DRESSING,
nothing else can be found so desirable. Containing neither oil nor dye, it does not soil white cambric, and yet lasts long on the hair, giving it a rich glossy lustre and a grateful perfume.

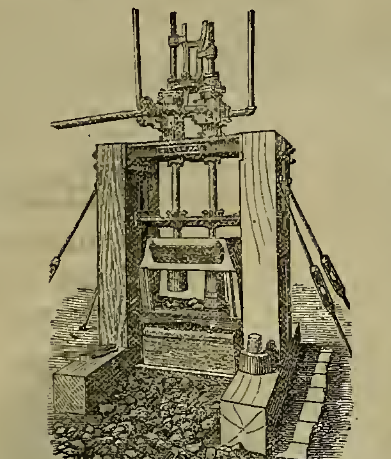
Machinery.

THE WILSON
Patent Steam Stamp Mill.



This extraordinary Mill, now so justly popular in the East, is now offered to the miners of the Pacific Coast. Having been in operation now for about eighteen months, the Company feel confident that the

WILSON STEAM STAMP MILL,

For Durability, Efficiency,

AND ECONOMY OF WORKING,

HAS NO EQUAL.

"The Wilson Steam Stamp Mill is the only Steam Mill that has had the severe ordeal of practical working, and proved itself eminently successful. It is now in operation in several of the Eastern States and Territories, and gaining an envious popularity. The whole machine is so simple as to be readily understood by the most ordinary minds. In fact, its simplicity is its durability. The expense of crushing rock or cement with this Mill is less than one-half the expense of any other Stamp Mill, and less than one-half the cost. For further particulars inquire of

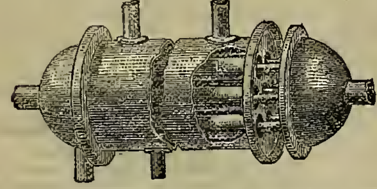
A. BICKNELL, Agent,
Nevada City, California,

Or of THE WILSON STEAM STAMP MILL CO., 326 Walnut street, Philadelphia, Pa.

Notice.—All persons are hereby warned not to manufacture or use any Steam Stamp Mills that are an infringement on the Wilson Patents, as they will be prosecuted to the utmost rigor of the law.

F. R. WILSON,
20v19-tf Supt. W. P. S. S. M. Co., Philadelphia.

CROSS' COMBINED
Heater & Sediment Collector



This Heater effectually prevents the collection and deposition of sediment in the boiler from impure water. From April 1, 1869, the Royalty on this Heater has been

REDUCED 45 PER CENT.,

Which enables the Vulcan Iron Works, McAfee, Spiers & Co., Risdon Iron Works, of San Francisco, Keep & Bargion of Stockton, and Williams & Co., of Sacramento, the parties having the right to build them, to furnish these Heaters at greatly reduced rates. Send for Circulars to

Crandall's Patent Spring Bed.

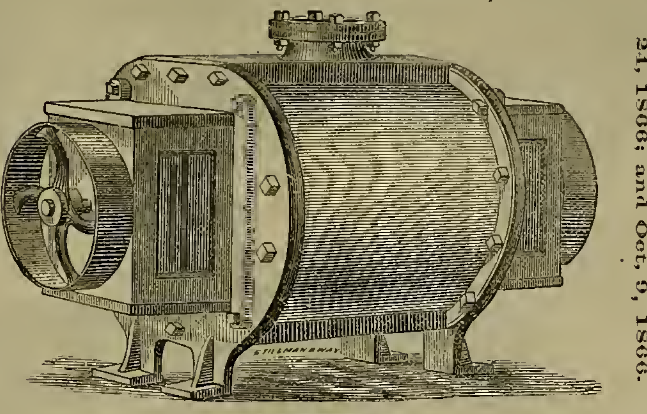
Manufactory, corner Front and M streets, Sacramento COOLEY, HENRY & CO., Proprietors. These Spring Beds, wherever known, are universally acknowledged to be superior to any other in use. They are light, durable and elastic, and present no harborage for bugs or any other kind of vermin, thus being free from the objections so often urged against the ordinary spring beds. ☞ Orders received at our manufactory, or at our agency in San Francisco. 7v20-3m

ROOT'S PATENT FORCE BLAST ROTARY BLOWER.

MANUFACTURED BY KEEP & BARGION,

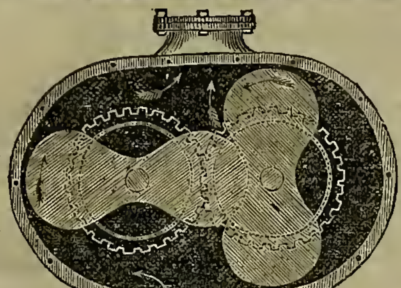
At the Globe Iron Works, Stockton, California.

Awarded the First Premium at the Paris Exposition.



Patented Nov. 1st, 1864; July 24, 1866; and Oct. 9, 1866.

ADAPTED FOR Smelting, Foundry, Mining and Steamships.



REQUIRES Fifty Per Cent. LESS POWER Than any Blower Now in use.

One of these Blowers may be seen on exhibition at W. T. Garratt's Brass Foundry, corner of Mission and Fremont streets. They are also in use at the Almaden Quicksilver Mine; Gridley's Foundry, Gold Hill, Nevada; Ætna Iron Works, San Francisco, and many other places.

Caution.—Purchasers will find it to their advantage to apply direct to the Stockton Agency, as certain parties, not authorized to manufacture the Blower, have put in the market machines of inferior construction, which do not answer all the requirements of the genuine article.

Quartz, Saw and Grist Mill Irons, Steam Engines, Horse Powers, High and Low Pressure Steam Engines, Steamboats and Propellers, made at short notice.

For circulars and further information, address

VARNEY'S
PATENT AMALGAMATOR;

These Machines Stand Unrivaled.

For rapidly pulverizing and amalgamating ores, they have no equal. No effort has been, or will be, spared to have them constructed in the most perfect manner, and of the great number now in operation, not one has ever required repairs. The constant and increasing demand for them is sufficient evidence of their merits.

They are constructed so as to apply steam directly into the pulp, or with steam bottoms, as desired.

This Amalgamator Operates as Follows:

The pan being filled, the motion of the muller forces the pulp to the center, where it is drawn down through the aperture and between the grinding surfaces. Thence it is thrown to the periphery into the quicksilver. The curved plates again draw it to the center, where it passes down, and to the circumference as before. Thus it is constantly passing in a regular flow between the grinding surfaces and into the quicksilver, until the ore is reduced to an impalpable powder, and the metal amalgamated.

Setlers made on the same principle excel all others.—They bring the pulp so constantly and perfectly in contact with quicksilver, that the particles are rapidly and completely absorbed.

Mill men are invited to examine these pans and setlers for themselves, at the office, 229 Fremont street,
1v1 San Francisco.

FOR SALE.

A Ten-Stamp Quartz Mill,

SAPOINE

FRAGRANT SAPOINE FOR THE TEETH

THE GREAT MEDICAL DISCOVERY!

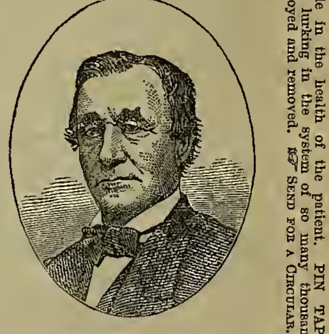
Dr. J. Walker's California

VINEGAR BITTERS.

More than 500,000 Persons

Bear testimony to their wonderful Curative Effects.

WHAT ARE THEY!



They are not a vile

FANCY DRINK,

Made of Poor Rum, Whiskey, Proof Spirits, and Refuse Liquor, doctored, spiced, and sweetened to please the taste, called "Tonics," "Appetizers," "Restorers," etc., that lead the tippler on to drunkenness and ruin, but are a true Medicine, made from the native roots and herbs of California, free from all alcoholic stimulants. They are the GREAT BLOOD-PURIFIER and LIFE-GIVING PRINCIPLE, a perfect Renovator and Invigorator of the System, carrying off all poisonous matter, and restoring the blood to a healthy condition. No person can take these Bitters according to directions and remain long unwell.

They are a gentle Purgative as well as a Tonic, possessing, also, the peculiar merit of acting as a powerful agent in relieving Congestion or Inflammation of the Liver, and all the Visceral Organs. In Bilious, Remittent and Intermittent Fevers, these Bitters have no equal. For full directions, read carefully the circular around each bottle, printed in four languages—English, German, French and Spanish.

One Hundred Dollars will be given for an incurable case, provided the bones are not destroyed by mineral poisons or other means, and the vital organs wasted beyond the point of repair.

For Inflammatory and Chronic Rheumatism, and Gout, Dyspepsia or Indigestion, Bilious, Remittent and Intermittent Fevers, Diseases of the Blood, Liver, Kidneys and Bladder, these Bitters have been most successful. Such Diseases are caused by Vitiated Blood, which is generally produced by derangement of the Digestive Organs.

Cleanse the Vitiated Blood whenever you find its impurities bursting through the skin in Pimples, Eruptions or Sores; cleanse it when you find it obstructed and sluggish in the veins; cleanse it when it is foul, and your feelings will tell you when. Keep the Blood pure and the health of the system will follow.

J. WALKER, Proprietor.

R. H. McDONALD & CO.,

Druggists and General Agents, corner Pine and Sansome streets, San Francisco, Cal., and 32 and 34 Commerce street, New York. 10v20-12t

☞ SOLD BY ALL DRUGGISTS AND DEALERS.

FOR FEMALE COMPLAINTS, whether in young or old, married or single, at the dawn of womanhood or the turn of life, these Tonic Bitters display so decided an influence that a marked improvement is soon perceptible in the health of the patient. PIN TAPE, and other WORMS, lurking in the system of so many thousands, are effectually destroyed and removed. ☞ Send for a Circular. ☜

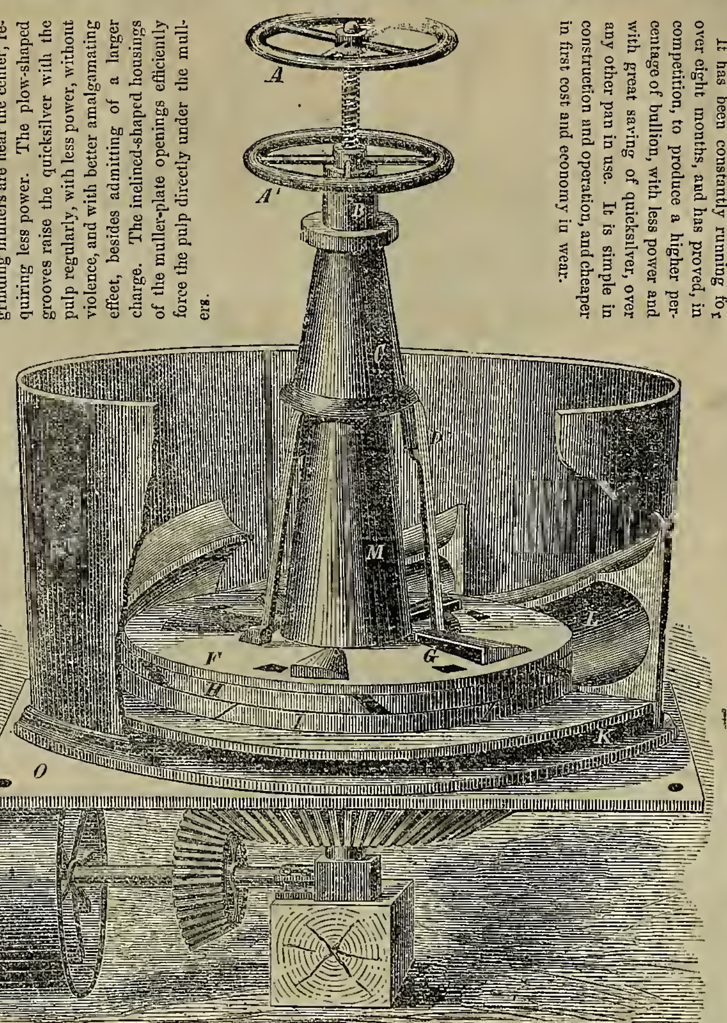
STEVENSON'S PATENT MOULD BOARD AMALGAMATING PAN.

This Pan is far superior to all others in several important particulars. The grinding mullers are near the center, requiring less power. The plow-shaped grooves raise the quicksilver with the pulp regularly, with less power, without violence, and with better amalgamating effect, besides admitting of a larger charge. The inclined-shaped housings of the muller-plate openings efficiently force the pulp directly under the mullers.

It has been constantly running for over eight months, and has proved, in competition, to produce a higher percentage of bullion, with less power and with great saving of quicksilver, over any other pan in use. It is simple in construction and operation, and cheaper in first cost and economy in wear.



Manufactured at the Golden State Iron Works (Co-operative), 19 First street, S. F.,
Where it can be examined and further particulars be learned; or persons may apply to the inventor and patentee, Mr. C. C. STEVENSON, at the Douglas Mine, Gold Hill, State of Nevada, where the Pans have long been in constant operation.

Important to Assayers.
Crucibles.
The Patent Plumbago Crucible Co.
Manufacturers of all kinds of
Melting Pots, Portable Furnaces,
CRUCIBLES, and other fire-standing Goods,
Battersea Works, London.

THE MORGAN PATENT CRUCIBLES have uniform quality, never crack, withstand the greatest heat without danger; heats more rapidly than any other; change of temperature has no effect on them; stand on the average forty to fifty pourings.

CERTIFICATES:

United States Branch Mint, San Francisco, Cal., March 12, 1869—Messrs. A. S. Hallidie & Co., Agents Morgan Crucible:—I have carefully tested the Morgan Patent Plumbago Crucibles purchased from you for the U. S. B. Mint, and cheerfully certify to their superiority and economy over all other Crucibles used by and under me. They are fully what you represent them, and I shall continue to use them in preference to any other. J. M. ECKFELDT, Melter and Refiner, U. S. B. Mint.

Eagle Brass Foundry, 206 Fremont street, San Francisco 12th March, 1869—Messrs. A. S. Hallidie & Co., 519 Front street—Gentlemen:—We have used and tested the Morgan Patent Plumbago Crucible, for which you are agents, and pronounce them superior to and cheaper than any Crucible used by us heretofore. GREENBERG & MOORE.

Messrs. A. S. Hallidie & Co.:—We have thoroughly and severely tested in every way the Morgan Patent Plumbago Crucible obtained by us from you, and find them superior to any we have yet tried, although we have used every pot obtainable in this market, we have none equal to the above, and concede your claims for them. We think they will average 45 pourings of brass. GALLAGHER, WEED & CO., California Brass Works, 125 Front street, San Francisco.

Assay Office of H. Harris, Silver City, Nevada, April 24, 1869—Messrs. A. S. Hallidie & Co.—Gents.:—I received from you three Crucibles of the Morgan make, which I have used since their arrival, and tested by constant use. Since 1847, when in the New Orleans Mint, I have always preferred the Crucible of Dixon's make over Adus, Gautier, and Taunton, Mass. Yours I find to be not alone of more finished make, but to stand double or treble the work of Dixon's Crucibles. The No. 12—the smallest sent—has stood so far 32 meltings, and is as good and sound as when received. Your Crucibles do not scale off like others; and as they are forty per cent. cheaper, I do not see why they should not be preferred by all assayers on account of durability and cheapness. Yours respectfully, H. HARRIS.

On hand and for sale by the Agents,
A. S. HALLIDIE & CO.,
18v18-9p 519 Front street. San Francisco

Sheffield Scientific School
Of Yale College, New Haven, Conn.

This department of Yale College, instituted in 1840, and endowed with the National Land Grant in 1866, furnishes advanced instruction in the various branches of Mathematical, Physical, and Natural Science.

The School is under the direction of the President of the College, a Board of thirteen Professors in differe special ties, and six assistant instructors.

Regular courses of study, leading to the degree of Bachelor of Philosophy, conferred by Yale College, are arranged as follows: 1—Chemistry and Mineralogy. 2—Civil Engineering. 3—Mechanical Engineering. 4—Mining Engineering and Metallurgy. 5—Agriculture. 6—Natural History and Geology, and 7—Select Course.

Advanced students are also admitted to optional courses, and if already College graduates, are received as candidates for the degree of Doctor of Philosophy.

Tuition, $125 per year of forty weeks.

The Libraries, Museums, Laboratories and Apparatus accessible to students, are varied and extensive.

For copies of the Annual Circular and Report, letters may be addressed to the "Secretary of the Sheffield Scientific School," New Haven, Conn. 13v15-1y16p

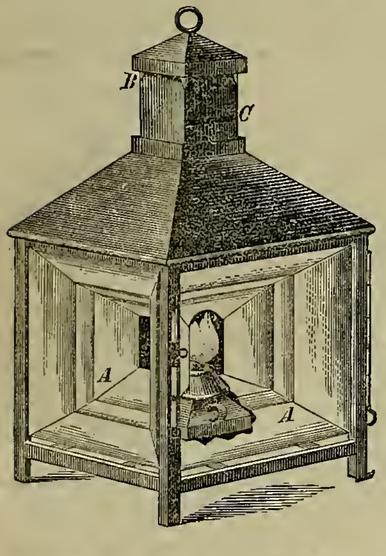
San Francisco, Saturday, April 23, 1870.

VOLUME XX.
Number 17.

The Central Reflector Lamp.

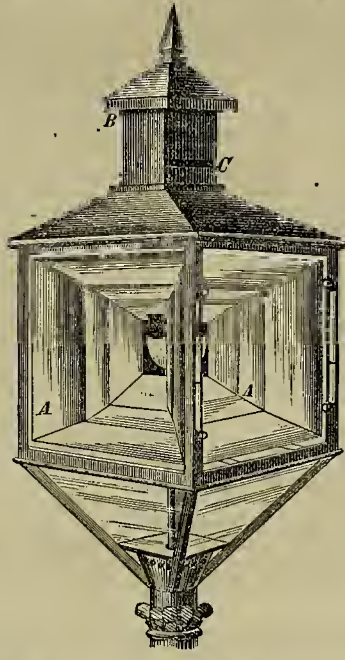
In our ordinary street lamps we lose the benefit of a considerable portion of the light which is produced. That which is diffused upwards, although by no means entirely lost, might still be better utilized by being thrown in a horizontal direction. Reflectors are employed to some extent and under certain circumstances, but a great objection to their general use is, that they throw the light only in a limited range and not around to all the points of the compass.

It is with a view of obviating these and other objections that the lamp, which we illustrate this week, was invented. It is designed with a view of economizing light by reflecting the rays in such a manner that none will be lost to utility. This lamp, it is claimed, will concentrate the light and give that direction to the rays which is most desirable for the purpose. The light is reflected horizontally in all directions, and also downwards, immediately around the post or standard, but not upwards. By its construction, the reflection is not objectionable on account of any dazzling brilliancy painful for the eye, while it is still none the less effective, and then again the flame will always be steady and undisturbed by high winds, strong draft or other similar causes.



The manner in which these objects are attained will be understood from the illustrations. The reflectors, A A, are made in the shape of three four-sided hollow pyramids combined, as often seen in crystals. The angles of the sides and their different sizes are in a certain proportion, which varies for different sizes of lanterns. Hence the rays of light do not all concentrate at a common focus, as in a common reflector, and the result of which is that the eye is dazzled and pained, but there are several foci, and hence the eye is assailed only by certain rays. Then the angles are such that the rays are projected, so that all shadows are avoided. When one is some considerable distance off, one sees more and a greater light, but on approaching, one eliminates one focus after another, and is not dazzled on getting close to the lamp.

In the figures, B denotes the ventilator-top. On the inside of this and directly under the openings, C, are the so-called guard-plates. These are plates which curve upward and inward. By this construction no wind can blow downward on to the flame, which will, consequently, always burn steadily, and by thus regulating the current of air, the more perfect combustion is obtained, and hence one gets a brighter light and at the same time economizes to a very considerable extent.



The lamp is made of different sizes and shapes, and the reflectors set at different angles according to application made. The device may be used for burning gas, oil or any illuminating substance.

The gas lamp consumes four feet of gas per hour and gives a light equal to 35 30-100 candles, where the common street lamp, consuming the same amount, gives a light equal to 11 34-100 candles. These numbers are given merely as examples, for the sake of comparison. One kind of gas will, of course, have a greater or less illuminating power than another.

The oil lamps are said, by actual test, to give a light equal to three common oil lamps, besides burning less oil. One gallon of coal oil will burn in these 124 hours.

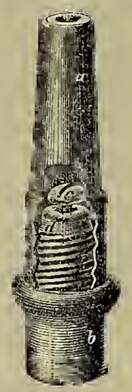
The proprietors are now manufacturing these lamps both for oil and for gas, and have flattering certificates as to the satisfaction given with regard to both light and economy. The reflectors are coated with a composition, we should state, which protects them from oxidation.

This lamp was patented April 5, 1870, by A. K. Grim and A. D. Moore, of San Francisco. Any person desiring further information can obtain the same by applying to A. K. Grim, room 23, Hayward's Building, California street, San Francisco.

Patent Regulator for Gas Burners.

Every house-owner who uses gas is periodically astonished when his gas bill comes in. The amount charged seems constantly on the increase, and he feels sure that he pays for more than he burns.

Such is, in fact, the case. To prove it, one needs only to burn gas in a room, where there are no strong drafts, for a couple of hours. On then coming into the apartment from the fresh air, one's olfactory organs will indicate the presence of unconsumed gases. The amount which thus escapes is very considerable, although differing according to circumstances. The owner of the patent, which we illustrate, claims, for instance, that with the common burner used in this city, from twenty to thirty-three per cent. more gas passes through the burner than is utilized.



Mr. M. B. Sturges, formerly connected with the St. Francis House, in this city, became satisfied that he could essentially reduce his gas bills by using a proper apparatus. After experimenting for some time, he invented his patent regulator, which he at once put up in all his rooms, and found that not only did he decrease his monthly indebtedness to the gas companies, but that he also had his house much better lighted. On applying for a patent, he found that he had been anticipated with regard to a part of his device by a man from the nutmeg State; but he purchased the rights of this person, and now holds the patent complete.

In the figure, *d* represents the socket of a gas burner which is screwed on the pipe in the usual manner. On the upper part, *b*, of this is screwed a common burner, *a*. In the middle of *b* is the regulating screw, *c*, the under surface of the head of which has a concave form. These different parts will be readily understood from the illustration.

Now the gas in issuing from the socket strikes against the concave screw head and is deflected down into the space between the socket and the burner, so that it then rises in a cone along the sides of the latter and then issues through the aperture. By this arrangement the pressure is removed from the said aperture to the regulating screw, and the gas flows from the burner in a steady and uniform manner, and not with such force that, as with the common burner, only a part has time to be consumed. By means of the screw, *c*, the amount of gas is easily regulated.

The owner of the patent intends going to work in a practical manner to introduce his device. As this can be put on any gas pipe, he proposes to affix it in any house, where the owner desires it, and let it be used without charge, when over a dozen burners are put on, for thirty days. Any person who is then not satisfied that he has gained by its use, can have them removed without expense on his part. From personal experience he has satisfied himself completely that his burner will save from 20 to 30 per cent. of gas, besides giving a stronger light and preventing the escape of the disagreeable and unwholesome gases.

Persons desiring further information may apply to M. B. Sturges, Bush Street House, 331 and 333 Bush street.

The "No-fence" Law.—A law designed to protect agriculture, and prevent the trespassing of animals upon unfenced private property, was passed by the Legislature of 1866, but made very limited in its application, as follows: To the counties of Marin, Yolo, and as much of Sacramento county as lies west and south of the Sacramento and Jackson road, the Third Supervisor District in the county of Solano, and the First Supervisor District in the county of Mono.

By a supplementary act of the last Legislature, this law is now made applicable, in addition to the above, to all of San Joaquin county south of the Calaveras river and all west of the San Joaquin; also, to the whole of Stanislaus county, and to all of Merced west of the San Joaquin. In all the regions named it is made the duty of owners of stock to keep the same within enclosures, making the owners responsible for any damages which cattle may do upon cultivated fields, whether such fields are fenced or not. The cattle themselves, when the owners cannot be found, may be sold for damage. Justices have jurisdiction.

European Patents.—Mr. Stevens, of Grass Valley, has applied, through the Scientific Press agency, for English patents on his improved grinder, concentrator and refiner, which has proved so successful with the copper ores of Lake Superior. This will be applied more particularly in England for treating tin ore, but can be used for slimes and tailings of all kinds of ore.

We have mislaid a clipping from the Central City *Register* inquiring about the advantages silver plating copper plates, but think that the questions asked have been answered in articles since published.

Agricultural Fair Appropriations.—The final action of the Legislature gave to the State Fair, at Sacramento, $3,000, and to each of the District Fairs $2,000.

Communications.

The New Copper Process.

[Written for the Scientific Press.]

Editors Press:—The reaction of iron chloride on copper oxide has long been known. I, myself, called attention to it in '55, through your columns, in reference to its bearing on pan amalgamation, and though then new to me, and to some chemists in San Francisco, it was not so to others, as was shown in a subsequent issue by "Delta." It had even then been applied to the extraction of copper at some place in Europe, the name of which I forget.

I made several experiments in the process, but experienced difficulty in the leaching, which Dr. Hunt appears also to have met with, and which arises in great measure from the precipitation of iron peroxide. It might be overcome by pressure. I have also tried the extraction of silver by the analogous process alluded to in your article; but, on account of the difficulty of leaching unroasted ore, and for other reasons, I have preferred to collect the silver with mercury.

It may be needless to remind your readers that these reactions are identical with those of the patio and fondo processes.

For those who think of trying to adapt Dr. Hunt's copper process to our ores, it may be well to remember that lead and lime oxides and carbonates decompose the iron chlorides, forming lead and calcium chlorides, which have no action on copper oxide unless, indirectly, in presence of SO^2 when the following reaction takes place:

$$CaCl + 2CuO + SO_2 = CaSo_4 + Cu_2Cl,$$

Forming lime sulphate and copper dichloride. In case sulphuric acid is not present in some form, the lead chloride will, in presence of excess of iron in the precipitating tubs, contaminate the copper with lead, which, however, can be redissolved by treating the cement copper with solution of copper dichloride. The reaction of solutions of neutral salts on the natural compounds of metals is a subject well worth the attention of metallurgists, and M. Terreil (*see Chem. News Am. Rep., June*, '67) has turned it to account in the proximate analysis of minerals, which is often even more important than the ultimate analysis, as it gives not only the elements present, but their state of combinators also.

Charles H. Aaron.

The Mines of Havilah, Kern County.

[Written for the Scientific Press.]

Editors Press:—In your issue of the 2d inst. I noticed a small paragraph inquiring the reason of the depression of the mining interests in and about this place. Here all of the best leads are in litigation, but we are looking daily for the decision in reference to the McKidney mine. Col. Rand has, we learn, returned from the East, and will soon resume operations. The ore from this mine will yield from $60 to $150 per ton. Such mines are scarce and should be in operation. There are good mines at Kernville, but the most of them are idle on account of attempts at black mail. [Our correspondent expresses some disapprobation at the course of the County Judge in certain matters.—Eds.] Messrs. Elleworth and Doland have good mines, yet all are idle except two, which are daily yielding ore which paye from $60 to $80 per ton. A. Staples run the same mines from January, 1864, until August, 1866, took out upwards of $500,000; and, to my knowledge, cleared $175,000, besidee making great improvements. He owned the mines as well as in other places. Ellsworth and Deland have since put up very fine hoisting works in company with J. P. Mead of San Francisco, but by their expensive improvements in the way of new mills, fine offices, boarding houses, etc., and from a bad winter of 1867 and 1868, they are all of $30,000 behind, as I have been told by Mr. Ellsworth himself; but men with capital could, if things were properly managed, make money very rapidly out of these very mines, the deepest shaft on them being less than 300 feet deep and with but little water to bother as yet. I am an old resident here, and if this is worthy of your notice, let me know, and I will take more time and will try to post you more thoroughly in the future.

A Miner.

Havilah, April 11, 1870.

[Many thanks to our correspondent, from whom we should be most happy to receive further interesting letters.—Eds. Press.]

Letter from White Pine.

[continued from page 250.]

What is called the Base Range, however, is not productive of base metal only, nor are all the mines of Treasure Hill yielding nothing but "chloride." One of the best mines in the former,—the Brother Conover,—has no base ore, while the Imperial, the Farewell, the Rosebud, the Mary Rogers, and many others, situated on the spur of Treasure Hill, abound in the same. The Virginia, on the eastern slope of the hill, also has considerable base metal. Mines of chloride silver are being worked as far north of Treasure Hill as two miles, and as far south as five miles; and there are numbers of mines of base ore in intervening localities. The attempt to define or describe any regular "belt" of country producing either free or base ore exclusively, is, therefore, preposterous. No such "belt" exists in this district.

Base Metal vs. Free Ore.

One advantage which the mines of "base metal" have over those of "free ore" is, that they may be owned and worked by poor men. The yield of ore is more regular, the mines are more easily worked, and the ore is more saleable from the dump. The reason of this latter is, the value and the character of the carbonate ore, and of argentiferous galena, may generally be seen at a glance; while the chloride requires a working result by mill process to determine its value. Besides, smelting is the cheapest method of the two, and the profit is larger, even with the great difference in the yield of silver from the two classes of ore. Lead is worth $160 per ton in New York, and $150 in San Francisco; and, with the increased facilities of transportation which the continental railroad affords, returns can be made to the smelter from the separating works in either section of the country in a much shorter time than from Swansea. The cost of insurance, which shipment to the latter involves, may thereby also be saved.

Shipping Bullion.

Our smelters have discovered these facts, and arrangements have been made by the agency of the Bank of California at Hamilton to make advances upon crude bullion shipped by them to New York, either for separation at Newark, N. J., or at Swansea, Wales. The bulk of bullion, I think, will go to Newark, while a large portion will reach San Francisco. The Chicago people are also moving in the matter of erecting separating and smelting works in that city, with a view of securing a portion of the business. The cost of transportation is as low to Chicago as to San Francisco; and there is no reason why Chicago should not have a large share of the product of these mines.

The mines of Eureka district, forty-five miles from here, although of base ore, are richer in silver than those of White Pine. The miners and smelters of that district are shipping their bullion eastward for refining. So that, although the "star of empire" may still be taking its way westward, the riches of our mining districts seem to be taking to themselves wings for an eastward flight. Perhaps your transportation companies may be able to give a reason for this.

Considerable bullion from our mills also now finds its way to New York for refining, instead of to San Francisco.

There can be but one result to all this, and that one is injurious to the interests of San Francisco. If this eastward current of silver and lead increases in volume, the whole of Eastern Nevada will soon receive its supplies of all descriptions of merchandise from Chicago and other Eastern cities.

Increased Activity.

But to return from this digression, and to conclude for the present my observations upon the mines of the Base Range, I would say that these latter are to be the principal source of the yield of this district in the precious metal during the ensuing summer. Many valuable locations now covered with snow to the depth of six feet, will be thoroughly developed and their wealth brought to light. The success of the owners of the Alta, Cadiz, Bounty, Imperial, and others, will stimulate prospecting to a remarkable degree. Even now, the miners wade knee-deep in snow, over trails which their feet have made, to reach their mines, so as to get them fairly opened early in the season.

Much more than I have written on these matters I shall be able to give you in my next.

W. H. M.

Shermantown, Nev.

The Gold Fields of Victoria.—No. 4.

Prospecting.

Much of the prospecting in search of a lead, whether of alluvium or quartz, is done by boring, the apparatus for which costs about one thousand dollars. It costs, under contract, from $3 to $5 a foot. They bore from the surface down hundreds of feet; from levels hundreds of feet below the surface they bore in every direction until they find, or are satisfied they cannot find, the object of their search. At Pleasant creek, for instance, they had reached a depth of 620 feet with Ford's patent rock-boring machine.

The older deposits of gold are found in deep leads, which exist in various parts of Victoria. They have to sink through hard basaltic rock, drift sand, etc. In search of the lead, the White Horse Co., Ballarat district, passed through 2 feet of surface soil, 10 feet of basaltic clay soil, 54 feet of basalt, 37 feet of clay, 79 feet of basalt, 46 feet of clay, 45 feet of basalt, 12 feet of black clay, 12 feet of brown clay, 7 feet of drift and gravel, and 11 feet of wash dirt; total, 315 feet.

The Crosbie Freehold, Ballarat, let a contract to prove ground by boring at $3.89 per foot. After passing through 126 feet of basalt and 80 feet of drift and clay, the contractor gave up the contract and forfeited the percentage retained as well as their deposit money.

Tribute.

Many of the companies contract to have the ore extracted on "tribute." In some instances the miners receive all the product to a given amount (the estimated working expense) and a percentage of all over that amount. In others, the mine owners haul and crush the ore and receive one-half the yield. In others, the tributers pay a percentage on the gross product, the terms varying with circumstances.

Examples.—The Bell Reef Co., Tarranger. The tributers were to bear *all* expenses connected with operations, receiving on all yields under $6 a ton the whole of the gold, and to pay the company ten per cent. of gross yield on all stone yielding from $6 to $20 a ton, and 20 per cent. on all stone yielding more than $20 a ton.

The Denmark Co., Bendigo.—Lode 1½ to 2 feet wide; company to haul and crush the ore, and to receive one-half the gold. Ore crushed yielded about $10 a ton.

The Golden Age, Bendigo.—Let on tribute at 15 per cent. gross.

Castlemaine.—A new feature in alluviul working is here presented by *two enterprising miners*, who have taken up Dinah Flat, erected machinery, and arranged with 50 Chinese to work the claim on tribute.

Wages.

The wages of miners range from $12.50 to $15 a week; of laborers, $10 a week; engineers, $20; machine blacksmiths, $20.

Managers.

They employ two—a mine manager and a legal manager—at salaries ranging from $20 to $30 a week. The duty of the legal manager appears to be financial and general supervision. In some instances a legal manager, receiving $30 a week, is prohibited from attending to any other business. Besides managers, a storekeeper or clerk is employed, whose salary is less than either of the managers. They have a board of directors and a chairman, who, for certain services, are entitled to fees.

Fuel.

The cost of wood ranges from $3 to $5 a cord, and from 75 cents to $1.25 *a ton* of 50 cubic feet.

Machinery.

The "Homeward Bound," at Scotsman, Ballarat, made a contract for a battery of eight stamps, with engine and boilers also complete, to be furnished *and erected* according to plans and specifications for the sum of $2,400.

The Waterloo Co., Talbot, made a contract for a battery of ten stamps, with winding engine, poppet heads, etc., for $1,720; and for a building to enclose the machinery, including material, for $465.

At Beechworth, a battery of 20 stamps, with engine 18¼-inch cylinder, a boiler 6½x26 feet, cost $4,470.

M.

◆

Submarine Enterprise.—The American Submarine Company of New York is fitting out a vessel for the purpose of recovering $5,000,000 of treasure from the wreck of a Spanish ship which sunk in the Bay of Cumana, Venezuela, in 1815.

Report of Samuel S. Fisher, Commissioner of Patents.—1869.

[continued from page 260.]

Female Copyists.

Prior to July 1st, 1869, much of the copying of the office was done by females. About sixty-five were employed, who worked at their own homes, and who were paid at the rate of ten cents per hundred words for the amount actually copied. By an act approved March 3d, 1869, provisions were made for fifty-three female copyists at an annual salary of $700. As it was obvious that this force must labor within the office, in order to secure proper discipline and efficient work, six rooms were provided in the Patent Office building for the entire number. These rooms and clerks were placed under the charge of an efficient female superintendent. It soon became evident that although the number of copyists was reduced, there were still more than sufficient to do the work originally performed by the larger number. Additional work was therefore assigned to them from other divisions, and the force of male clerks was correspondingly reduced. Accurate time tables have been kept since July 1st, 1869, of the attendance of these ladies and a careful record has been made of their work.

The result of the experience of six months is that the attendance is nearly as good and the work is fully equal in quantity and quality to that of male clerks performing corresponding duties. The salaries of these ladies was originally fixed at $700 only, instead of $900. This, it is presumed, was an oversight, as they have labored as faithfully, and until November 15th, 1869, one hour per day longer than the female clerks of any other department. I know of no reason why their pay should not be equal to that of male clerks of like grades, except that there are, as nearly as can be ascertained, twenty-five applications for position by women to one from men. This division is the largest in the bureau and is under excellent discipline, yet the superintendent of it, because a female, has with difficulty been enabled to secure the pay of a first-class clerk. I recommend that the pay of the female clerks be raised to at least $900 per annum; that they be paid at tharate from the beginning of the present fiscal year, and that permanent provision be made for a female superintendent, at a salary of at least $1,400 per annum.

Salaries.

Principal examiners are now paid $2,500 per annum, while first assistant examiners receive $1,800, and second assistants $1,600. The difference between the assistants is but $200, while between the first assistants and principals it is $700. There is not a corresponding difference in duties, qualifications, or ability. I submit that if the salaries of first assistants were fixed at $2,000 the scale would be more equitable.

The character and necessary qualifications for the examinere and chiefs of divisions require adequate compensation to secure the best men. These positions ought to be filled by permanent incumbents, and a sufficient price should be paid to retain them in office. That this is not yet done appears from the fact that they voluntarily resign to accept other positions or to go into business as solicitors. Every second assistant examiner now in the office, twelve of the twenty-first assistants and seven of the twenty-two principal examiners were appointed during the year 1869; of these, twenty-five were appointed to fill places made vacant by voluntary resignations. In the other departments of the office, while it is doubtless true that many young unmarried men are amply paid, it is also true that experienced clerke of mature years are poorly compensated. Under the last appropriation bill not a single fourth-class clerk was assigned to the Patent Office.

[to be continued.]

◆

Frozen Giant Powder Dangerous.—The Alpine *Miner* of the 19th inst. says this fact was plainly shown a week or two since by Mr. McCuen, of Silver Mountain. Finding the powder more compact in the box than usual, he went to work digging it up, when it took fire and burned so rapidly that his house was entirely consumed. This changing the nature of Giant by freezing is now considered the greatest objection to it, and we hope some remedy may be found therefor. In the meantime let those who have anything to do with this powder be very careful to place it where it will gradually thaw out and become loose and soft before using or handling. Don't try to use it in the congealed state, or even handle it, except with great care.

Mechanical Progress.

The Most Economical Steam Pressure. At a late meeting of the Polytechnic Association of the American Institute, Mr. Chas. Emery exhibited a table which he had prepared to show the proportion of power lost in overcoming the back pressure in non-condensing engines. Although it is true that the higher the steam pressure the less in value becomes the back pressure, it does not follow that the economy increases proportionately. By the table it appears,—he says,—that "the savings due to an increase of steam pressure are important up to, say 90 or 100 pounds. Above that point, however, they are too small in my opinion to overcome the well known disadvantages due to high steam. There is a saving of only seven per cent. by increasing the pressure from 90 to 195 pounds, which will hardly equal the losses due to increased leakages, radiation, strain on boiler, etc., to say nothing of the popular feeling of greater danger. By still further raising the pressure to 300 pounds the increased saving would be only 2.4 per cent. On the contrary, it will be seen that carrying less than 80 pounds steam pressure in a non-condensing engine, as is too much the practice, is simply throwing away fuel. I have found, by careful experiments, that the best practical results are obtained with pressures varying between 80 and 100 pounds, and consider that higher pressures are of advantage only where light weight is of paramount importance."

Hamar's Anti-Carbonizer for Gas Retorts.—The accumulation of carbon in the retorts has been a nuisance to gas manufacturers, and efforts have been made to remove it; but all attention has been given to removing the accumulated carbon, not to preventing its accumulation. A recent invention of Mr. A. Hamar consists in introducing jets of steam into the retorts. The oxidation of the coke sets free hydrogen, which combines with the free carbon in the retorts, forming carburetted hydrogen, which is pushed off from the retorts by the surplus of steam, increasing the quantity of gas produced, and purifying it so as to add to its illuminating power. A three-quarter inch steam pipe is extended from the boiler along the top of the wall behind the stand pipes, provided with a stop-cock near the boiler and a waste-cock on the other end of the pipe. With this pipe are connected half-inch pipes, which extend to and penetrate the mouth piece of each retort far enough to allow an elbow to be attached, in which is screwed a pipe ten inches long, reduced at the end by a sharp angle to a quarter of an inch, for the purpose of forming a jet. All the pipes are provided with stop-cocks near the mouth-piece.

"Pebble" Gunpowder.—The English Ordnance Select Committee appointed to determine by experiment the gunpowder which is attended with the least risk of overstraining the guns, has fixed upon the above and advised its adoption provisionally. *Engineering* says of it: "The new powder has a density ranging from 1.79 to 1.82; it is produced by breaking up "press cake" of the specified density into lumps, which are retained between sieves of five-eighths and four-eighths in chmesh respectively. The lumps are afterwards submitted to the ordinary process. The name of the powder sufficiently describes its appearance. The introduction of a powder of this sort amounts to increasing the strength of our guns without augmentation of weight, and to increasing the power of our armaments without augmentation of cost."

Pointing Pins by Electricity.—As a substitute for grinding, C. Widemann suggests that pins may be pointed by making a bundle of them form the positive pole of a galvanic battery, which pole is then dipped into an acidulated liquid contained in a vessel into which the negative pole of the battery has been previously conveyed through the bottom. The bundle of pins or wires is not brought in contact with the negative pole, but a small space is left between. In a short time the current which passes through this space causes the action of the acid to produce points upon the ends of wires equal to those of the best English pins.

The Fluo-Titanic Process.

We condense the following notice of this new American discovery from *Van Nostrand* for April:

"This process has for its object the production of wrought iron and steel from crude cast-iron, by the use of fluxes, and without manual labor. There has been the want of a process economical as to cost and certain as to results, that will produce superior qualities of wrought iron and steel from pig irons that are too poor for the Bessemer process (and which comprise over 90 per cent. of the pig-iron produced), and from which better results are to be obtained than by puddling. These conditions are fulfilled in the new process, which consists in the combined use of fluor-spar and titaniferous iron ores with liquid cast iron, for removing carbon, silicon, sulphur and phosphorus. This differs from other processes in the respect that it is reducing as well as oxidizing, and is not attended with waste; on the contrary, the iron in the titaniferous ore is rendered metallic by the reactions of the oxygen in the ore with the carbon in the pig iron,—causing, in fact, a slight gain in weight.

Several modes of application have been tried with success. In one, granulated cast iron was charged into a furnace in admixture with the ore and spar, both pulverized. When the iron melted, the heat dissolved the spar, which combined with the titanic acid in the ore; and, by reason of the affinities of these two for carbon, silicon, sulphur and phosphorus, these substances were taken from the iron in the form of vapor and slag, leaving the resulting wrought iron in the liquid state, to be run off into ingots to be hammered or rolled. Another method is to mix the ore and spar, rendered plastic by means of heat or by mucilaginous substances, and to run the molten cast iron in upon them. In order to produce steel of any required grade, it is only necessary to vary the proportions of spar and ore and the grade of the pig iron."

Compound Engines Want New Boilers. We take the following from "Scotch Notes" in a late number of *The Engineer*:—"The ordinary type of engine appears to have got into the background for a time. I am inclined to think, however, that it is only for a time, The compound engines in the mercantile marine have unquestionably given wonderful results of late in respect to great development of power on small consumption of fuel; and if they would continue to do so, it might be said that the compound engines must prevail. But it is a question of time. When the boilers are new, pressure of 80 lb. or 90 lb. may be borne with safety; and with steam of such pressure, and cylinders steam-jacketed, expansion may be carried out to an extent that will exhibit remarkable results. But a few years will tell severely on those high-pressure boilers. Notwithstanding their use of fresh water, other destructive agencies are at work—arising from the use of surface condensers—of baneful character as affecting the longevity of marine boilers; and engineers have been baffled to find an antidote. When such boilers are under Government inspection such high pressure will soon be disallowed. Year after year the inspector will take off 10 lb., 20 lb., or 30 lb. per square inch of the load on the safety valves, in proportion as the boiler shows decay. And then how fare the compound engines? Take away their high steam, and they are crippled. Expansion becomes impracticable in proportion as the pressure is reduced, and so the engines become ineffectual."

Electro-Deposition of Iron.—We find the following in the London *Mining Journal* of March 19th; Mr. W. C. Robarts, the chemist of the Mint, has achieved something surprising with his specimens of electro-deposited iron. The source of the deposit is a solution of sulphate of iron and sulphate of magnesia; the rate of deposit is about the same as with copper, and the iron thus obtained is so hard that it will scratch glass. Among Mr. Roberts' specimens, exhibited at the Royal Society, were bank-note plates, medallions, mouldings, and raised work of various kinds; and one plate had been converted into steel by a process which was not revealed."

Prof. Ward's Museum.—It seems that this was fully insured, and has been paid for. Prof. W. is as ready as ever to furnish casts of fossils to colleges. A large portion of the moulds were saved. He is on the point of leaving again for Europe to renew his collections.

Scientific Progress.

Relation Between Light Produced and Gas Consumed.

The January number of the *American Journal of Science and Arts* contained a paper read by Prof. Silliman at the August meeting of the American Association, in which "Farmer's Theorem" was discussed. This theorem, so named because first demonstrated by Mr. Wm. Farmer, of New York, is as follows: "The intensity of gas flames—*i. e*, illuminating power—increases (within the ordinary limits of consumption) as the square of the volume of the gas consumed." It has heretofore been customary to compute it as increasing directly as the volume of gas consumed, instead of as the square of that volume. Prof. S. details a number of experiments with different coal gases and various forms of burner, and says that the results point clearly to the general truth of the theorem. Prof. Wurtz fills a large part of the space devoted to the *Chemical Repertory* for April 2d with notes and communications upon the subject. Among the latter is one from H. H. Edgerton of the Fort Wayne (Ind.) Gas Works,—referring to and reproducing a letter written by him in 1868, enunciating the same proposition and stating that his experiments had satisfied him of its general truth as opposed to the ordinary method of estimation. Prof. Wurtz says: "No doubt can reasonably be held that we have here another of those extraordinary cases, so numerous in the history of scientific discovery, of independent travelers simultaneously pushing on in precisely parallel paths and arriving at identical stand-points."

Origin of Diamonds.—In 1864, Dr. Göppert, in an essay which gained a prize at the Haarlem Academy, argued in favor of the formation of the diamond by the wet way. He now publishes,—says the *Quarterly Journal of Science*,—an account of certain diamonds containing organic structures tending to confirm his views. Two diamonds in the Royal Mineralogical Museum in Berlin were found to inclose numerous green cells closely resembling those of many algæ. One of the diamonds, weighing 263 milligrammes, contains a very large number of perfectly round green granules, which appear to be isolated cells not unlike those of *Protoccus pluvialis.* The new species is accordingly named *P. adamantinus.* In the second diamond, weighing 345 milligrammes, the cells are less rounded and more elongated in form, while they frequently unite so as to form a loose parenchymatous tissue; they find their best representatives in *Palmoglea macrococca*, and Göppert has accordingly ventured to name the new diamond plant *Palmaloeites adamantinus.*

Vegetable Parasites.—The following is from a paper read by Dr. N. S. Davis before the Illinois Microscopical Society; "It is a fact worthy of note that vegetable parasites have been found only in connection with diseases of such structures as are covered with epithelial cells, like the skin and mucous membrane, or on suppurative surfaces, where the organic cells are undergoing more or less degeneration. This suggests the question whether all these parasitic forms are not the results of what Erasmus Wilson has styled *Phytiform*—degeneration of cells and granules of animal matter? Whatever may be the differences of opinion in relation to the nature and mode of development of these simple parasitic bodies, found in connection with epidemic and some endemic diseases, all agree that their production and rapid multiplication are directly dependent on the co-existence of three things—viz.: organic matter capable of undergoing degeneration or decay, moisture, and a temperature generally above 60° F. If, with these, we have coincidently the exclusion of sunlight, we have the conditions most favorable for all vegetable parasitic formations."

Prof. Hunt on Volcanoes and Earthquakes.

The following is quoted, somewhat condensed, from Prof. T. Sterry Hunt:

"Judging from the known properties of the rocks with which we are acquainted, solidification should commence not at the surface, but at the center of the liquid globe, a process which would, moreover, be favored by the influence of pressure. This augments the melting temperature of matters, which, like the rocks and most other solids, become less dense when melted, while it reduces the melting point of those which, like ice [or bismuth], become more dense by fusion. Pressure, moreover, increases the solvent power of water for most bodies, whose solution may be described as a kind of melting down with water into a compound whose density is greater than that of the mean of its constituents. The theory adopted by Hopkins and by Scrope, is briefly as follows: The earth's center is solid, though still retaining the high temperature at which it became solid. At an advanced stage in the solidifying process the remaining envelope of fused matter became viscid, so that the descent from the surface of the heavier particles, cooled by radiation, was prevented, and a crust formed, through which cooling has since gone on very slowly. There were thus left between this crust and the solid nucleus, portions of yet unsolidified matter (or even perhaps a continuous sheet), and it is in this that we are to find an explanation of the phenomena of volcanoes and earthquakes.

This theory is an approximation to the one which I adopt, though differing from it in some important particulars. While admitting the existence of a solid nucleus and a solid crust, with an interposed stratum of semi-liquid matter, I consider this last to be, not a portion of the yet unsolidified igneous matter, but a layer of material which was once solid, but is now rendered liquid by the intervention of water under the influence of heat and pressure. When, in the process of refrigeration, the globe had reached the point imagined by Hopkins, where a solid crust was formed over the shallow molten layer which covered the solid nucleus, the farther cooling and contraction of this crust would result in irregular movements, breaking it up, and causing the extravasation of the yet liquid portions confined beneath. When at length the reduction of temperature permitted the precipitation of water from the dense primeval atmosphere, the whole cooling and disintegrating mass of broken-up crust and poured out igneous rock would become exposed to the action of air and water. In this way the solid nucleus of igneous rock became surrounded with a deep layer of disintegrated and water-impregnated material, the ruins of its former envelope, and the chaotic mass from which, under the influence of heat from below and of air and water from above, the world of geologic and of human history was to be evolved."

Areas of Preservation.—This term now replaces that other, "Centres of Creation," which belongs to the language of the past. Prof. Gray says: "The conclusion tardily reached, 'that the present geographical distribution of plants was in most instances a derivative one, altered from a very different former distribution,' has been followed by the conviction that the present species themselves are equally derivative, and have a changeful history, some steps in which may be dimly surmised by the study of cognate forms, extant or fossil. At the point now reached, if not by general yet by large consent, the problems we are led to consider are such that it is indispensable to have a term of wider application than "species;" and Mr. Bentham here appropriates to this use the word *Race*, to denote either permanent variety, or species, or groups of two or more near and so-called representative species."

Fertilization of Plants.—Professor Hildebrand states that plants intermediate between the *Papaveraceæ* and the *Fumariæ* gave the greatest quantity of seeds when impregnated with the pollen of another individual of the same species; less when the pollen was from another flower of the same individual, and least when the impregnation took place within the flower itself. For *Eschscholtzia Californica*, the proportion of seeds in these three cases was twenty-four to nine to six. Professor Fewzl says that he obtained abundance of seeds from two species of *Abutilon* by fecundation with pollen from other individuals, and that these operations are best performed between eight and nine A. M.—*Nature*.

Mining Summary.

The following information is gleaned mostly from journals published in the interior, in close proximity to the mines mentioned.

California.

ALPINE COUNTY.

Items.—*Miner*, 9th: Good Hope prospects cheerful....Leviathan matters are said to be assuming a go-ahead shape; a gentleman from London being here looking over matters.....The manager went to Reno last week to attend the experiment on the first lot of Exchequer ore by Stetefeldt furnace. In regard to the most important question—the success of the furnacs for our ores—reports unite in saying it is all the most sanguine could expect. The rumors as to product of the ore are more conflicting; varying from $100 to $1,400 per ton.

AMADOR COUNTY.

The Butte Canal.—*Ledger*, April 16th: In view of the undoubted completion of this ditch by August 1st, a large amount of mining ground along the route of survey has been already taken up and recorded. We think this fall will witness livelier times in Amador than we have seen for a number of years.

BUTTE COUNTY.

The Prospect.—Oroville *Record*, 16th: These are better than for years. Hewitt's claim, White & Co's, Gallinger's, Moore's, Young's and others, are in successful operation.

The Kennedy Flume Co.—This company, which purchased 40 acres of the eastern portion of the Fernandez grant, have placed a flume in a ravine extending nearly through, and are opening up a claim in the west bank, which shows two or three strata of excellent dirt. We believe this is the only placer claim in the State where the miners own the title in fee. It is known that the whole body of their purchase will pay for working. The first clean up will take place about the first of May.

Cherokee Flat.—The surveys for the Spring Valley canal are progressing, and the rich placers of Cherokee and of Table Mountain will soon be supplied with water.

CALAVERAS COUNTY.

Mining Items.—*Chronicle*, 16th: Kiler & Boughton's new hydraulic, on Sport Hill, is running; another claim is to be opened shortly....Overton & Co., who discovered new diggings near Rich Gulch Flat, are taking out "the stuff" in quantities; several other claims are successfully worked....Mining operations at the Buckeye are as brisk as usual....Paul & Co. have adjusted their difficulties, and work in the mine has been recommenced....The Harkins mine keeps up its reputation of being the best in the county; the yield is enormous....Brackett reports plenty of good gravel; Shaw ditto....Nothing new in quartz; the mills in this vicinity are pounding away with fair results....We understand that negotiations are pending for the purchase of the Woodhouse mine. The "Coffee Mill" machinery, recently purchased by Lewis Bros. & Co., is being taken down for removal to their mine near Railroad Flat.

Railroad Flat.—Cor. of same: Harris' mill is crushing rock from the vicinity of Independence. At West Point, the miners, as a general thing, are in placer mining, and the majority are doing well. Mr. Thoss lately worked some rock from the Petticoat mine which yielded beyond anticipations. At Independence, the claim of Reynolds, French & Kerr, after a lengthy run, produced a handsome yield. The claim of Snndermyer & Co. is paying well. Poe's vein is being worked, and although it is small, some of it is very rich rock.

Monitor Camp.—Cor. of same: The Merrimac Co. are driving a gangway to their shaft which will tap the mine 90 feet from bed-rock. As soon as this is completed a six-inch force-pump will be put into the shaft. On Central Hill things are looking up. Staples & Smith are rigging up their hydraulic, and in a few days will commence operations. Benson & Bright, with about 70 feet pressure, are running off gravel at a 2.40 rate. Van Regan & Clouse washed up Saturday. Their claim has paid well from the start, and a few days ago they obtained $10 to the pan. A. Brown is taking out good pay gravel. The Jackson boys have been washing their tailings; they resume work in their claim next week. The Davis shaft is now 40 feet deep, and shows a ledge eight feet wide. Free gold can be seen in most of the rock. The Tyrone tunnel is thought to be near the channel.

Rich Gulch.—We have these items from a private source: The 15-stamp French mill will start up in two weeks. The Frank Barney lead has been leased to Clerc & Co. for three years, and work was commenced on the 1st inst. The tunnel is in 320 feet, and the lead is 7½ feet wide. Shaft down 50 feet; 60 feet more to reach tunnel. Sixteen tons of rock worked $1,135. The Lewis lead, near the Frank Barney, also worked well.

EL DORADO COUNTY.

Quartz Hill.—Placerville *Democrat*, April 16th: Mr. Fiske struck his first prospect 25th of February, since which time, though 60 years of age, and working alone most of the time, he has taken out, according to his own statement, and no one doubts it, $3,000. This amount has been taken from a hole sunk upon the ledge not deeper than eight or ten feet, nor more than twenty feet in length. Hodge & Co., whose claim is north of his, have taken out as much as $100 to the pan. They have done but little work in getting out rock, but have been removing top dirt.

A telegram of 16th says: There is a great quartz excitement in Placerville. One hundred dollars to the pan have been realized in the claim of L. C. Fiske. Over 500 claims were staked off this afternoon. Hodge & Co. have taken out over three pounds of gold to-day. Fiske has taken out over $400 to-day. People are crowding in from the adjacent country.

[The last of the two accounts of same date given above seems mixed. For divers reasons we prefer the first.—Eds. Press.]

Gold Dust.—By express from Placerville during the week, $15,834; from Coloma, 2,000, making $17,834 in all.

INYO COUNTY.

Cerro Gordo.—Los Angeles *News*, April 9th. The steady flow of bullion from Cerro Gordo district continues.

KERN COUNTY:

The Joe Walker Mine.—Visailia *Delta*, April 13: One day last week we saw five large teams and some twelve or fourteen wagons pass through town, loaded with new machinery for the Joe Walker mine, consisting of hoisting works and a powerful pump.

MARIPOSA COUNTY.

Mining Notes.—*Gazette*, April 15th: Benton mills are thundering away at the Pine Tree rock. Douglass has struck good rock at 300 feet depth in the Mary Harrison mine, and has set a force at work on the Melvina. Ralph Jones, on the extension of the Melvina, has taken out good rock showing free gold. Several parties are preparing to commence or renew mining operations. Negotiations are in progress for the purchase of the Marble Springs mine.

NEVADA COUNTY.

Star.—*Transcript*, April 12th: A rich ledge was struck by the contractors on Friday in the Sanford incline. The ledge is large and the rock rich. This is the second good ledge struck since these parties took the lease, and they propose to commence running the mill about the first of June. They have 300 tons of rock on hand.

A Big Thing.—Same of 16th: A elaty looking ledge of rock 300 feet wide, which crosses Marker's new road, was located some years since by John Pattisou, and has been worked yearly enough to hold it. The last test made was at the North Star mill, and the yield per ton was $26. The work required this year to hold the ground has just been done, and a tunnel of 75 feet run. As the hill is precipitous and the lead runs directly across and through it, backs of any depth may be obtained, and the softness of the rock and the tremendous size of the ledge would make it pay by mill process if the yield were only $2.50 per ton.

A Gang of Celestials.—Same of 17th: John Hawke has 56 Chinamen employed in his claims on Deer creek, under an agreement by which he is to pay them 20 per cent. of the yield.

The Mulberry Ledge.—Stiles' mill commenced crushing rock from the Mulberry, belonging to Burnell and others. The rock looks rich. The crushing was thirteen tons, and the yield $16.80 per ton.

Contract.—Hawkins & Co. have taken a contract to sink 100 feet upon the shaft of the Pittsburg for $25 per foot. The Co. is now taking out first-rate rock.

Consummated.—The sale of the Buckeye Hill and Sweetland creek claims has been consummated. Evans, Stidger & Co. sell to the Sweetland creek miners, a corporation organized under the laws of the Kingdom of Great Britain and Ireland. The amount paid was $200,000.

Orleans Mine.—A contract has been let by the Co. to run a tunnel 80 feet upon the ledge. The rock looks well and the sulphurets are rich. An assay of the latter yielded $768 per ton.

Heavy Sale.—W. B. Bourne, of San Francisco, has purchased three-fourths of the Empire mine. The other fourth is owned by Captain Lee, Supt. Mr. Bourne owns half of the Pittsburg, has $75,000 in the North Star, and three-quarters of the Empire.

Eureka.—Grass Valley *Union*, 13th: Yesterday the regular melt of gold took place. The proceeds of twelve days' run of the mill were put into bars worth, in the aggregate, $25,500. This does not include any gold from sulphurets.

Grass Valley Consolidated.—Same of 14th: Good judges say that the rock now being taken from the ledge will yield, by mill process, over $100 per ton.

Greenhorn.—Same of 15th: This mine for a month has yielded 320 ounces of gold—or over $5,000 in coin. In this time 298 tons were crushed. The cost of taking out and crushing was about $7 per ton.

PLACER COUNTY.

Clark & Hazelton.—Grass Valley *Union*, 17th: This ledge, on the south side of Ahurn ravine, just across from the town of Ophir, is showing well. Four tons of quartz have been crushed, and the yield was nine ounces of gold, or about $36 per ton. The shaft is down 15 feet, and the ledge is about a foot thick. Prospecting is active in the vicinity of Ophir and is growing more so every day.

SAN BERNARDINO COUNTY.

Heavy Suit.—*Guardian*, 16th: A suit has been instituted by Richard Garvey against the Pittsburg Co. for damages of $40,000. Mr. G. lately obtained a judgment against that company for the gold mines at Holcombe Valley. He has now a good mill upon the property, has 15 men engaged, and the rock is known to be rich.

SAN DIEGO COUNTY.

The New Mines.—The San Francisco *Bulletin* of the 18th has seen private letters giving these items: The discovery shaft on the Stonewall Jackson ledge, in Quillmac district, has been sunk 30 feet, developing a well-defined ledge, four feet in width, of very rich quartz. Free gold in abundance can be discovered on the entire surface, and specimens from any part of it, pounded roughly up, yield an excellent prospect. Two hundred feet north another shaft has been sunk, striking the ledge at a depth of 10 feet, and displaying very rich decomposed quartz. The boulders and dirt above it were covered with small particles of free gold to such an extent that it is supposed it would pay to sluice the stuff off for surface digging. The extension has been taken up, and prospectors are trying to find it. Julian district is progressing well. The Washington has been opened to a depth of 30 feet, and shows a vein of very rich stuff 3½ feet wide. The owners ask a most extravagant price for a small interest.

SIERRA COUNTY.

Mining Items.—Downieville *Messenger*, 16th: The Caledonia Co. is running toward the Star Co's ground, expecting every day to strike rich gravel deposits. The Pioneer Co., of Grass Flat, through their contractors, Stover & Co., are hammering away at their bed-rock in their main tunnel. They are now 1,500 feet in. The Union Co. at Port Wine have dirt which pays from four to six dollars per car load. The Monte Cristo Slope Co. are still driving towards their rich dirt along the Union Co's line. At Council Hill, Messrs. Hughes, Howell & Co. are working their rich diggings. Boyce & Bro. are piping very rich bottom dirt. The Sear's Union Water Co. are raising their shaft. At Union Hill, Miles, Evans and Daniels are doing well in their hydraulic diggings. Lafferty & Co., in Poverty Hill, sold one-half of their claims and tunnel for $26,000, and are driving their tunnel fast. They are opening hundreds of rich claims, their tunnels coming in from Gold Run ravine.

The Iowa Co., near Mt. Pleasant ranch, have a 30-horse power engine on the ground, and will sink their shaft to the bed-rock next May.

SISKIYOU COUNTY.

Quartz on Scott Bar.—Yreka *Union*, 16th: On Saturday, Thos. Ryan and two others, with an ordinary hand mortar, pounded out over $800, which they sent to this city by express. The discovery of the ledge has created an intense excitement in the neighborhood.

TRINITY COUNTY.

Dutton Creek.—*Journal*, 16th: Dixon & Co. have run back into the hill 60 or 70 feet, and find better prospects than ever. They are now putting up a hydraulic and building a wagon road. Two interests have been sold for cash. The first, Peter Mooney to John Hurst, for $300. The second, Dan Connor to Charles Schopps, for $600

McGillivray's.—Stoddard & Lovett are opening a new claim below Smiley, on Trinity river. Faubel has opened another claim, which, from all accounts, must be remarkably rich.

Lewiston.—Miners have been making good use of what water they have had. Blagrave brothers will make considerable money. Cunningham & Kellogg, on Bolt's hill, have been working extraordinarily rich ground.

YUBA COUNTY.

Bateman Mine.—*Appeal*, 16th: J. F. McKean, of Camptonville, sold the Bateman mill and mine yesterday to W. H. Gleason, of San Francisco, who intends to start it in the course of a few weeks.

Marysville telegram, 18th: Silas Edgmon has discovered a rich quartz ledge on Rich gulch, in Eastern Yuba; one pan of decomposed quartz yielded $100.

Indian Ranch.—Cor. of *Appeal*, 19th: Several extension claims have been taken up and recorded on the Edgmon ledge, and times look lively.

Arizona.

Big Bug.—Prescott *Miner*, April 2d: At latest dates Gray & Co's ten-stamp mill was working on ore from the Eugenie extension. The placer miners had commenced operations in the old Mexican gulch.

Walker District.—The Eureka ten-stamp mill, after having run a short time on ore from the Box Elder, was shut down for repairs. Some good looking ore from the Pine Mountain was being hauled to the mill. All the arastras, and the hydraulic claims of Wells, Bowers & Bean, were running. Water was getting scarce.

Lower Lynx Creek.—One of the Bashford and two other men took out in four days $52, with a very small head of water. Burns & Co.—three men—on the opposite side of the creek, were making four dollars a day, with rockers. Another Co. of five men were digging a ditch to carry water on "Frenchmans Bar," in which they had found large beds of gravel. Lower down, opposite the old Mexican Camp, one of the miners had taken out a piece worth $13.75. Joseph Revoirs and another man, above Jackson & Co., took out seven ounces last week.

Hassayampa District.—The Sterling mill was started several days ago. Wormser and Tompkins say it is the *easiest* running mill in the Territory. Some 30 or 40 placer miners are doing well.

Colorado.

Briggs Mine.—*Register*, 6th; At Hussey's, yesterday, was a retort from the Briggs, the product of the mill for March. It weighs 407 ounces; currency value, $7,500. The amount of smelting ore sold was sufficient to pay all the expenses of mine and mill.

Items.—Same of 18th: Moody & Dowell are panning and rocking from the Cassius lode, in Russell gulch, an average of $25 a day....Richard J. White, in Russell gulch, took out 20 ounces with three men last week....Drake & Sons, working the "Williams," Lake gulch, are about 100 feet deep and report a 15-inch pay-vein, and a 4½ feet crevice. A 15 pound sample taken as an average of the entire pay-vein yielded in England about $200 gold and silver, per ton.

Idaho.

Idaho City.—Cor. of *Statesman*, April 14th: Miners in Boise basin are beginning to get to work in earnest, ground sluicing and starting work generally.

Warren's Diggings.—Cor. of same: Two tunnels have been run into the Rescue ledge, tapping the vein at the depth of 130 feet. This lead averages $46 per ton in gold. A new mining camp has been struck 10 miles north, consisting of placer diggings. Thus far claims yield from five to twenty dollars per day to the hand. New diggings have been found on the South Fork of Salmon river, 10 miles south of here, the richness of which is greater than I dare write until further confirmation.

Owyhee.—*Avalanche*, 16th: Only 10 men are employed on the Poorman. Upon an average, one ton per day to each man is taken out. There are over 200 tons of good looking ore on the dump. A larger force of hands will soon be put to work. Dan Monroe is foreman on the Empire, which is worked night and day. The vein is two and a half feet wide and shows well in silver. The Baxter has been leased to Wilford, France & Co. The main shaft is down 240 feet. The hoisting is done by a whim worked by a mule. Exceedingly rich silver ore, mixed with ruby, is being taken out 70 feet north of the bottom of the shaft. The vein varies in width, sometimes three feet and at other times six inches. A blast is seldom required. About 70 tons of ore are on the dump that will yield a handsome dividend. Ore immensely rich in gold is being taken from the Corduroy, now incorporated under the name of Mahogany. The rock in the Golden Chariot is as rich as ever, and the vein averages two feet. In the Ida Elmore the ore is getting richer in the fifth level, where the ledge is from twenty inches to three feet in width.

Montana.

Red Mountain City.—Correspondent of the Virginia *Times*, April 8th: The Langworthy Flume Co. are constructing a derrick and hydraulic works. The Red Mountain Co. will have a derrick rigged shortly. On the Nevins hill things are brightening. The Only Chance Co. have put on a stronger force of men, and have gone to work at their arastras. The Nevins tunnel is within 8 or 10 feet of the lode. On Gold Hill, Dickey & Co. are taking out rich ore from a five-foot crevice, and the St. Peter Co. are pushing work with energy. Harvey & Day, Moose creek, are getting a big pile of silver ore on top of ground.

Pioneer.—*New North-West*, 8th: Pemberton & Kelly have 3,000 feet of hydarulic pipe on Glasgow Bar. They own 2,400 feet of the Bar, and will run from four to six hydraulics during the summer, depending on the amount of water.

Cariboo.—We learn that 75 inches of water was flowing in the gulch on Monday. The snow is all off the flats, and mining will commence next week. There are only 12 or 15 men in the gulch, and there is work for 40 or 50 more.

Cable City.—Deer Lodge *Independent*, 9th: The machine of the Cameron Co. will be in place in a few days, and the Co. will then employ nearly 50 men.

Operations.—Silver Bow, Rocker City. and Butte, will be resumed this week. Spring Gulch ditto.

Highland.—Dickey & Carter, on Gold Hill, have a 5-foot crevice, containing rock which will mill on the average $40 per ton. The incline is down 30 feet. Fifty tons ore now on dump. They will erect arastras.

Cedar Creek.—Cor. of Helena *Gazette*, April 4th: The boys are getting good prospects on every claim in Barret district, above and below discovery, wherever they have found bed-rock. Every man here seems to be well satisfied with the camp. Claims in the upper part of Cedar gulch, anywhere in Barret district, are held at figures ranging from $600 to $6,000. Several claims have sold lately for $1,000 each. Manhart, Vanhoose & Co. bought No. 25, 26 and 27 above discovery, to-day, and paid $1,800 for the three.

The *Capital Times* gives part of a Cedar Creek letter, in which the writer says: "Yesterday I was offered $4,000 for No. 4 above discovery, which I refused. Claims are selling at from $1,000 to $4,000, and difficult to be had. It is an easy thing to wash out from 25 cents to $5 to the pan in the district of which I am recorder." The *Times* thinks this should be taken with a grain of salt.

Nevada.

HUMBOLDT.

Battle Mountain.—Galena cor. of *Register*, 16th: The Mary Ann and Alaska are yielding rich ores, and are considered next to the Little Giant. Six miles from Battle Mountain two smelting furnaces are being erected by Martin, Bruce & Co. A considerable portion of the material is now on the ground. The works are made more extensive than at first contemplated for the purpose of smelting copper ores, immense veins of which exist in Copper Cañon, a short distance from the works. Two miles from the furnaces is Galena. The mines are all around town, and blasts are heard at all hours. But a limited amount of labor has as yet been expended on the veins, although we can speak with certainty of the richness of the ore. New ledges are being discovered almost daily.

Railroad District.—The Grass Valley *Union* of the 16th gives extracts from a letter to John Bradley of that place. We quote: "Chunks of galena weighing from 500 to 1,000 pounds can be taken from the Visalia mine. But the chief of the district is the Wisconsin Chief. This is the 'old be' copper mine, and appears to be a regular ledge, in width from two to twelve feet. The ore generally comes out in large green blocks, weighing from 500 to 600 pounds. We had one lot worked in San Francisco, and the yield was 40 per cent. of copper and $70 per ton of silver. We have had assays as high as 60 per cent. of copper and $225 per ton of silver. The Mountain Boy is a better class of ore. The piece we send you is about 60 per cent. copper, with silver at the rate of $87 per ton. The Boomerang is also a copper mine and has good ore. The New Year's Gift is rich in silver."

WASHOE.

Gould & Curry.—Gold Hill *News*, April 16th: Daily yield, 95 tons; average assays, $52. The ore body in the El Dorado section is yielding well. The drift from the El Dorado tunnel to intersect the Potosi will reach it in two weeks.

The Monitor mill, below Johnston, was burned on Sunday night. The value was $12,000.

Alaska.—This is the district discovered three months since. In the first ledge found, Norris, McCloud and Reed have sunk a shaft 85 feet deep. They find the ledge from two to three feet in width, of a fine white quartz, containing streaks of black sulphuret silver ore, pronounced the best of that character in the State outside the Comstock, assaying from $60 to $360 per ton.

WHITE PINE.

Review.—*News*: The representatives of two English companies are now here, and Chicago, Philadelphia and New York have their agents on the lookout for investments. Outside districts report no changes, save that good mines have been found in Ely, six miles from the Pioche ledge. Silver Park has one mill running and another will start up toward the end of the week. Chicago is about investing heavily in Shoshone. Cooper is turning out rich ore, both from the Blue Lead and chloride belt. Clifton district (Deep creek) is opening well.

Items.—The Stanford mill, 30 stamps, started up on the 15th on ore from Aurora South. Hauling has been going on steadily since the mill shut down for want of water, and there is a large supply of ore at the batteries....Alsop smelting establishment is making a successful run, and up to last evening had turned out 1,300 bars of bullion, of the average weight of 90 pounds—making 117,000 pounds....Trench mine has opened into a splendid vein at a depth of 33 feet. The vein is six feet wide, all rich ore. Forty tons has been extracted, which is estimated at $1,000 to the ton.... We are indebted to Fred Hatch for a large boulder of horn silver from the Bradshaw mine, Red Hill, Silver Park....Gen. R. M. Wilson writes from Eureka: "We have been running for the last 10 days, averaging three tons of metal per day. The furnace stands well. Prospects on every side are encouraging."....Work has been commenced in Robinson district. Cummings is quarrying rock to build a smelting furnace. Forty assays from one mammoth vein show an average of $266 per ton in silver....Late accounts from Kern district are encouraging. The shaft on the Mother Ledge has been sunk 50 feet, and a drift run across the vein 21 feet, through good smelting ore all the way, except three feet next the hanging wall, which belt is milling ore of great richness....Experienced miners estimate the ore in sight in the Hidden Treasure at from 25,000 to 40,000 tons, and that it will average over $100 per ton, by mill process. Nevertheless, only low grade ore is being sent to mill....Aurora South extracts 35 tons ore per day....Wabash is getting good ore....Eberhardt is looking better than ever. The lower tunnel shows ore, some of which goes $600 to the ton.... Aurora Consolidated ore is not assorted, yet mills $53 per ton....Bourbon is taking out good ore.

Yellow Pine.—Mr. Chas. Scott, one of a company of eight which left San Francisco some time since to work the Excelsior lead, has returned with some smelting ore for reduction, which, so far as tested, yields $60 per ton in silver.

New Mexico.

Items.—*Press and Telegraph*, April 1st: The Montezuma Co. on Red river have run a tunnel 180 feet into the mountain at a depth of 100 feet. The silver vein struck is wide....A clean-up at the Chester mill from one cord of the Great Eastern lode quartz, netted 4 oz. and 16 dwts. in gold....The Atlantic Co., Orleans Flat, are down 90 feet, and find the quartz richer....The Monarch lode, Bell & Co., has two shafts; one 70 and the other 25 feet in depth, with a five-foot crevice and paying quartz.

Wyoming.

The Big Horn Expedition.—A Cheyenne telegram of the 15th says that Judge Howe's mission has been successful and that the exploration will be permitted to go. The object is the exploration of the country to the north of the Union Pacific Railroad, in Wyoming Territory, from the base of the Black Hills to the Big Horn Mountains.

San Francisco Mining Stock Market.

MISCELLANEOUS STOCKS.

Comparatively few transactions have been effected in the miscellaneous market since our last issue.——San Francisco Gas is in better favor than for some weeks past, realizing $89@90 per share.

MINING SHARE MARKET.

A very fair business has been done in the Stock Board during the past week, however the very marked recession in a number of prominent stocks has had the tendency to circumscribe speculation somewhat, and to check the actions of the more legitimate dealers. Gould & Curry, Amador and Savage sold to a large extent and under a sharp fall, while other prominent stocks have been well maintained, and some exhibiting a slight advance. As a general thing, the mining share market lacks bouyancy.

Hale & Norcross—received moderate attention at shading prices. For the week closing April 16th, 1,115½ tons were extracted against 1,120½ tons the previous week. They have on hand at dumps 6,169½ tons, of which amount 2,485 tons is low grade. On the 17th, they sent down $27,433 in bullion. The seventh station is now completed, and on the 19th inst. the drift had been carried forward twelve feet, had reached the ore of the vein, which is pronounced to be of good quality. This station is on the west side of the shaft in hard rock, and will probably not require repairing for years. The winze is down 55 feet below the sixth station, continuing in good ore. In this winze they have not yet reached the east or west wall, and they have no idea of the width of the vein at any point in it. At the north end, between the fifth and sixth levels, all the ore of any value is worked out. The greatest portion of the ore obtained from the sixth level is now taken from that portion of the mine lying between a point 85 feet south of the shaft to a point 50 feet north of the shaft, and most of the vein in this locality is as yet unworked. In the old mine the ore breasts are large, and continue to look favorable, yielding from fifty to sixty tons of ore per day.

Gould & Curry—was in the market to a considerable extent, at a very material decline. During the week ending April 18th, 654¾ tons of ore were extracted; previous week, 675 tons. To drift No. 3, running west from the seventh station, twenty-three feet have been added, running through porphyry and clay. Cross-cut No. 2 continues in very hard and flinty quartz, nine feet only having been made during the week. The old ore-chambers show a more promising appearance. On the 19th inst., $13,322 in bullion came to hand. Philipp Deidesheimer has been appointed Superintendent at the mine, in place of Isaac L. Requa, resigned.

Chollar-Potosi—has been in active demand, at well maintained rates. For the week closing April 15th, 1,400 tons of ore were extracted, against 1,300 tons the previous week. All ore-producing sections have an encouraging appearance, and the ore is yielding better returns. From the new shaft, in the west drift, they have commenced a branch to the north, to connect with the fifth station of the Potosi shaft, and have carried it twenty-four feet toward the north drift. On the 19th inst., $32,150 in bullion was sent forward to the office in this city. The average assay of the latest ore-yield has been $81 23 per ton.

Overman—evinced considerable animation toward the close, at a lessened price. During the week ending April 17th, 1,135 tons of ore were extracted from the following localities: Upper tunnel, 638; lower tunnel, 406; and 500-level, 91 tons. In previous week, the aggregate yield amounted to 1,094 tons.——**Sierra Nevada** shows a yield of 359¼ tons for the week ending April 14th; previous week, 390 tons.——**Ophir** changed hands to a large extent, at a recession from opening rates. On the 19th inst., the drifts at shaft No. 1 were going ahead well, and the water was steadily decreasing. Shaft No. 2 is being timbered, and they have commenced the third station drift. At the first station, the face of the breast does not look as well as it did the day previous.——**Occidental** levied an assessment of $6 per share.

Kentuck—continues quiet, at a slight decline. During the week closing April 15th, 355½ tons of ore were extracted, the 65 per cent. assay-value being $5,250 68—equal to $14 79 per ton.——**Crown Point** ruled at a lessened price. For the week ending April 15th the yield amounted to 528½ tons, the 65 per cent. assay yield being $6,077 35, or $11 31 per ton.—*Commercial Herald.*

Treatment of Rebellious Silver Ores, by Charles H. Aaron—a pamphlet of eight pages, of concise reading, of practical value to parties interested in the subject. Printed and sold by Dewey & Co., at this office, for 25 cents, post paid.

San Francisco Prices of Copper Ores.

San Francisco, April 21, 1870.

W. T. Atwood states the following as approximate price at which copper ores can now be sold in this city. There is no sale for ores which assay less than 10 per cent.:

	Per ton.		Per ton
12 per cent. ore	$24 00	18 per cent. ore	$41 40
13 " "	26 65	19 " "	44 65
14 " "	29 40	20 " "	48 00
15 " "	32 25	25 " "	62 50
16 " "	35 20	30 " "	75 00
17 " "	38 25		

Ores assaying above 30 per cent., $2.50 per unit. Bars at the rate of 13c. per lb. for pure copper.

The Gold-Bearing Rocks of Nova Scotia.—Prof. Hind has lately made a preliminary report on the rocks, representing the Laurentian system of Sir W. Logan. He considers these rocks to consist of sedimentary deposits, altered by metamorphic action, and that their crystalline structure was produced before the deposition of the gold-bearing rocks which lie uncomformably upon them. Gold is found and worked in the Laurentian rocks in Canada, as at the Madoc mines, and it is not improbable that mines may yet be opened in the Laurentian of Nova Scotia. The area occupied by the Laurentian in Nova Scotia is, probably, not less than one-half that part of the country which has hitherto been represented on geological maps as Lower Silurian. The Laurentian being auriferous inferentially, may yet turn out to be as valuable in mineral wealth as the Silurian deposits now worked. In Canada there are, besides gold, beds of magnetic iron ore, of sulphurets of iron and copper, and of titaniferous iron ore in these rocks, which may also be found in the Laurentian of Nova Scotia, and being in close proximity to the coal fields, may yet prove a great source of wealth.

Farming and Gardening.

Communications for this department are solicited from all parts of the Pacific States and Territories.

Iron for Peach Trees.

Much complaint is made in various parts of California about the early decay of the peach tree, and we believe the greatest trouble in the mountains is experienced in the small valleys and ravines, where the soil is composed of a rich, black mold, comparatively free from the red dirt of the hills, the color of which is due to the notable amount of oxide of iron which it contains, while the trees growing in the red soil are more healthy and longer-lived. The reason for this difference has generally been attributed to what is supposed to be the too vigorous growth of the tree in the valleys, whereby its vitality is exhausted. We are inclined to believe that the decay is, in a large measure, due to a lack of iron in the soil.

At a recent session of the New York Farmers' Club, this question of the value of iron to the peach tree was discussed, and the general impression seemed to be in its favor. A gentleman from Long Island exhibited specimens of different peach trees, which five years ago were badly infested with borers and affected by the "yellows;" but which were now vigorous and healthy. This change, he claimed, had been wrought by the use of iron. He had applied iron filings, etc., about the roots, and the borers and other insects had ceased to infest them, while the "yellows" had disappeared. He would give his peach trees a mulching of ten-penny nails, if no other form of iron could be obtained. Another gentleman, Mr. Crane, also gave in his testimony for iron. He had a large experience in peach-growing, and had seen the good effects of iron in the soil, upon both tree and fruit. He had found the muck from a bog meadow, into which flowed iron springs, a most excellent fertilizer for the peach. Mr. Bruen had cultivated peaches twenty years; had used iron in every shape, and in unlimited quantities; but where trees received good culture and were kept free from borers, he had not found iron to benefit. Of course, good culture, otherwise, might take the place of iron; and, as a general thing, the borer will be *drowned out* of a peach tree, by its sap, if it is kept in a thoroughly vigorous condition. It is seldom that a borer will attack a really healthy and vigorous tree. The instinct of the creature tells him what will be his probable fate if he does so.

There can be little doubt about the value of iron to a peach tree, and we feel confident that it might be advantageously applied throughout the Sacramento and coast valleys. Tons of a very good material might be gathered up about the foundries in this city. In the interior, fruit-growers might throw all their old scraps of iron into a shallow vessel of water, where, by evaporation, or drawing off of the same, the iron might sometimes be exposed to the action of the atmosphere to hasten its oxidization. The water saturated with the oxide of iron should be applied to the surface of the ground about the tree; or scraps of iron might be buried in the ground about the roots. The former would be much the best plan. The slag from iron furnaces might no doubt be ground up and used to advantage.

Prof. Horsford of Cambridge has found phosphate of iron on the upper surface of leaves and in the skin of fruits. If fruits require iron, and none or very little is in the soil, it must be added by the orchardist. Copperas—sulphate of iron—should not be used, or only very sparingly, and then always with lime.

W. H. Seward, Horatio Seymour and Jay Crooke own farming lands in Iowa.

Brain-work on the Farm—Figures for Farmers.

Those who think there is any necessity that lands should grow poor as they grow old are laboring under a very serious error, and may find food for reflection in the fact that not many years ago the average yield of wheat in England was about ten bushels per acre, while the yield is now over *thirty* bushels! Brain-work has accomplished this improvement.

The average yield of wheat on *new* lands in California exceeds that of the present average yield in England; while the yield of our *exhausted* land is but little, if any, greater than the average there before the introduction of their present improved system of agriculture. Our general average here is twenty bushels to the acre, at which rate of yield it will not pay to raise wheat in England.

But little, if anything, can be made by raising wheat at prices now ruling, with our present mode of culture on the worn out lands of California. The only mode of successful cultivation of such lands is by adopting here, perhaps in a modified form, the improved mode of culture now employed in Europe. We feel thoroughly impressed with the idea that money judiciously spent in that way will return one hundred fold more to the California farmer. The cost of fencing, plowing, seeding and harvesting an acre of land that yields only fifteen bushels is just as much as that required for an acre that yields thirty bushels; while the net income from the latter is from five to six times as much as that from the former. A statement of the case may be made as follows:

LAND PRODUCING FIFTEEN BUSHELS TO THE ACRE.		
Fifteen bushels, say at $1 each		$15 00
Seeding, harvesting and cultivating	$10 00	
Thrashing and sacking, 15 cents	2 25	12 50
Net profit per acre		$2 75
LAND PRODUCING THIRTY BUSHELS TO THE ACRE.		
Thirty bushels at $1 each		$30 00
Seeding, cultivating and harvesting	$10 00	
Thrashing and sacking, 15 cents	4 50	14 50
Net profit per acre		$15 50

The above figures show a profit of more than five fold from good or highly-cultivated land over that which has been worn out or badly tilled; and hence the importance of securing a large yield to the acre. The question then comes up as to the extra cost for fertilizers, and the improved mode of preparing the soil, which will be hereafter considered. The best way, however, is for each farmer that is in doubt to experiment for himself, which he can readily do by measuring off a single acre for careful cultivation and comparing its yield with the ordinary crop or with that of another field similarly situated by its side.

Experiments in the Use of Manures for Wheat.

Carefully recorded agricultural experiments are rare; in fact are almost unattainable. One of the most persistent experimentors in this direction is Mr. J. B. Lawes, of England, who has been engaged for 23 successive years upon the same land. In one of his reports upon the advantages of manuring land for wheat, he gives the following comparative results for the years 1863, 4, 5 and 6:

	1863.	1864.	1865.	1866.	
Unmanured	17¼	16	13½	12½	bushels
Farmyard manure	44	40	37⅜	32⅝	bushels
Artificial manure	55⅝	49¾	43¼	43⅞	bushels

The average of the same field for fourteen years, from 1852 to 1865, was—unmanured, 15½; farmyard manure, 35¾; artificial manure, 39¼.

Mr. Lawes says that the progressive decline which is shown in this statement is due to the variation of the seasons, and not to the gradual deterioration of the land, as might at first be supposed, as the full returns for the entire term of fourteen years abundantly prove. Unfortunately, Mr. L. does not give the amount or value of the manure he employs.

The secret of successful farming is, beyond all question, hidden in the manure heap; and it is found not so much in the quantity as in the quality of the fertilizer employed, although it sometimes happens that failure is produced by an overdose of high-seasoned stimulants, such as guano, highly-concentrated poudret, compost from the hen-roost, etc. As a general thing a cubic yard of highly-concentrated manure, evenly and properly spread, is about the right quantity for an acre. Of common barnyard manure, well rotted and properly composted, about 160 cubic feet, or one cord and a quarter, should be employed. Europeans accomplish wonders by the use of liquid manures. The Chinese do the same, as may be seen by carefully watching their operations in their gardens about this city. About one gill to the square foot of such manure is generally employed.

In California.

One of the most ready means by which California might arrest the present rapid deterioration of her lands, is that of the introduction of diversified farming, which would involve rotation of crops and give us greater facilities for the manufacture of stable manures. In the absence of that, fallowing and plowing in green crops is perhaps a better resource than any large importation of mineral fertilizers, unless, perhaps, we except the article of gypsum, which can be furnished here very cheap as soon as there is any considerable demand for it. Gypsum, in addition to its direct value to growing crops, will also be found highly advantageous as a stimulating agent in the growth of green crops for plowing under.

Those who have practiced fallowing and plowing in green crops have already learned its benefits, and will be slow to give it up. We propose to devote a column to this subject in our next issue, in continuation of the present article.

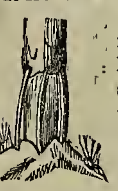
Shoeing Plows.—A planter near New Orleans finding that he used up plows faster than he could afford to replace them—a somewhat paradoxical condition in agricultural economy—determined to turn Yankee for once and invent something to meet his wants. He has done so. His invention consists in covering plows of any kind with a thin plate of steel on their turning faces and landsides in such a manner that it may be easily taken off and replaced. Plows that formerly wore off rapidly at the point may now have their lives indefinitely prolonged by putting on a new face. They are made in New Orleans, and the South now proposes to rejoice in release from absolute dependence on the North for plows. Californians, above all others, ought to be able to appreciate an improvement of this kind, which is so familiar and useful to them in their mining practice; but which we believe is now, for the first time, introduced into agricultural economy.

A New Plum.—Judge Hanaan, of Luray, Clark county, Missouri, describes, in the St. Louis *Journal of Agriculture*, a new, native plum, which he says "has not failed to bear a very full crop, annually, since it began, eight years ago. It seems to belong to the Chickasaw family. *Fruit*—small, about one inch in diameter, round, yellow, sweet; the best equal to the green gage, in the opinion of many; firm and acid until mellow,—colors long before it is ripe. * * * It withstands the attacks of the curculio, with me, while the green gage, etc., by its side, are entirely destroyed."

Norway Oats in California.—A shipment of the famous Norway oats has recently been received at Marysville, for seed. This crop is said to yield remarkably well, and also to be superior for feed. Its straw, whether threshed or cut before ripening, for hay, is also said to be superior to the ordinary varieties. If all is true that is claimed for this new cereal, its introduction here must be regarded as a great gain to the State. It may possibly have an especial adaptation for California.

Girdled Trees.

Badly girdled trees may be easily saved by the process herein described when all other methods might possibly fail. The accompanying engraving will enable the reader to more perfectly understand the description. The engraving is copied from *Moore's Rural New-Yorker*, and was originally designed to meet an especial case, where a large number of peach trees had been badly girdled by mice; hence the wound is represented as at the extreme butt of the tree. It will apply, however, equally well to any portion of the trunk. The *modus operandi* is described as follows: Cut from the trees branches of green wood the length required to connect the bark above and below the injured space, then sharpen them at each end to the shape of a wedge, drive a narrow, sharp chisel into the bark above and below the girdled space and press each end of the sharpened twigs firmly into the cuts made by the chisel. Then wax the gnawed space well, or coat it with gum shellac, or bind about it with cloth and string, fresh excrement from the cow stable. Care must be taken to have the bark on the body of the tree, and that branches therein driven meet or coincide. It is very easy to save trees in this way—peach, pear or apple. Attend to it at once. Do it thoroughly, and the trees will scarcely show that they have been injured.



The Standish Steam Plow.

It will be recollected that we gave an account a short time since of some work being done by this plow in Petaluma. The *Argus*, which at that time noticed the exceedingly perfect manner in which the work was done, has since made the following reference to the effect which the thoroughness of the work has exerted upon the crops growing upon the ground prepared. We copy as follows:

One of the most convincing proofs of its utility is to be seen in a comparison of the growing crops on land plowed in the ordinary manner and by the steam plow. An examination shows that the latter has a most decided advantage. While, as above stated, the ground worked by the steam plow is found level, smooth, and thoroughly pulverized, and the grain standing at this time some six inches in height, and evidently distributed throughout, in a field immediately adjoining, and of the same character of soil, but plowed with an ordinary plow, the grain is scarcely three inches high, very unevenly distributed, nearly choked with weeds, and the field generally presenting but a sorry figure when compared with its neighbor. The superiority is due to the thorough pulverizing of the soil to a uniform depth, the destruction of all weeds deleterious to the growth of the crop and the even surface of the ground after the plow has performed its work.

The scene of operation of the plow is within sight of our office, and as we have from the first felt an interest in its practical working, and have from time to time spoken of it, we feel that this further recognition of its merits is now due. The inventor, from causes which it is not necessary to name, was unable, with this imperfect machine, to make his work perfect; but he has studied with the closest care and attention all its defects, and, having secured abundant means, is now at the East, engaged in constructing an improved plow which will possess these advantages: 1st, it will plow and plant forty acres per day, at an expense of one-fourth that required to perform the same work in the ordinary manner; 2d, it can be run night and day, and, owing to the rapidity of its work, will enable the farmer to put in a large crop in a few days, when the soil is in proper condition to be worked; 3d, by its use land that would otherwise be nearly worthless, can be reclaimed and made to produce good crops; 4th, it pulverizes the soil to a uniform depth, leaves the surface smooth, and insures the complete destruction of the weeds that often outgrow and choke down the crop; 5th, it does its work in a manner every way superior to that done by horse-power and must ultimately supersede the latter on level land; 6th, by detaching the plows, the machine can be used as a reaper and thrasher, or for any other purpose for which steam power is required.

Potatoes Improved by Grafting and Hybridizing.

Until quite recently new varieties of potatoes have been produced by planting the seed contained in the potato balls. Lately, however, successful experiments are said to have been made in improving this valuable tuber by a new process of hybridization, which involves the mixing of the juices of two kinds or more, so as to modify, and perchance improve both, or unite the desirable qualities of two in one. It is said that absolutely new varieties have been thus produced.

In grafting a true scion upon a tree or woody stock, we merely substitute the grafted scion for the original stock; no new variety is thus produced, although some modification in the habits of a tree may be brought about, as when a tall, straight growing one is grafted or budded into a dwarfish, spreading tree. But in grafting the potato there is no production and continuance of woody fiber; the result is merely a commingling of juices and sap of the two kinds, resulting in a change in the nature of the tuber produced by the union—a sinking of a bad quality, the production of a new one or the commingling of those already existing. Generally the qualities, good or bad, are retained, but more or less modified. The amalgamated product is, of course, capable of continuing its kind by future planting. The mode of conducting this operation is described in the Canada *Farmer* as follows:

Take any two sound potatoes of different varieties, whose good qualities you wish to retain; cut out all the eyes of one of them entirely with a common pocket knife; then cut out a piece of the potato in the form of a wedge, and substitute for the bit so removed, a piece having a good eye or two, nicely sprouted, about half an inch long; then tie firmly together with a piece of bast matting, or string, having first run a couple of ladies' hair-pins clear through both potatoes. These hair-pins will prevent the tie from slipping off the potatoes, as well as assist in holding both parts together. The fit must be a good one, and the bark or rind of each must meet as in any other mode of grafting. The operation must be performed quickly, and the grafted set must be planted as soon as possible, as the sap would dry up if exposed for any length of time to the air. The trench should be opened and manured, ready to receive the grafted tubers, and they should be placed therein and covered up quickly with the soil. Rounds may be grafted with Kidneys or *vice versa*, or Rounds may be grafted one on the other. Let it be perfectly understood that not every one can graft potatoes successfully, and because you fail don't blame the system. The operation should be performed by a person who thoroughly understand grafting fruit trees; then there is a chance of success; but even he may fail in it.

Another Plan.

Another system is to take two potato plants, growing close together, of different kinds; when the plants are well sprouted, remove the earth, and take care that you have only a single stem from each potato; put the stems close together; graft the stems by inarching, binding the stems together with a soft elastic bandage, and covering the bandage with wet clay or grafting wax spread on cloth, so as it may be removed when the stems have united. The result (if the operation is successful) is, that the tubers on each plant will show a great variation from the original kind; and as these variations, in the present state of knowledge on the subject, will be entirely chance-work, you will have to select from the produce, and try the tubers the second year, before the benefits, or otherwise, can be ascertained.

This process, might, no doubt, be applied to other tubers than the potato, and possibly, by the "inarching" process, to other than tuberous plants. Why might not this latter "inarching" process be advantageously applied to the various kinds of fruit, the union to be continued from both roots, until fruit is produced, or until scions can be taken for ingrafting into standard stocks? Would not such a reunion, by a mixing and amalgamating of saps, produce a joint variety, which might be subsequently continued by budding or ingrafting in the ordinary way? Inarching, as usually employed, is only another form of engrafting, and used only when the cut scion is not to be easily united to the desired stock. We are not aware that experiments have been made by keeping up the union of the two roots until fruit has been produced, although it may be that such experiments are familiar to others.

A correspondent of the *Journal of Agriculture* questions the statements of the *Farmer* correspondent as to the results claimed from the above process. It *has* rather an unreasonable look; but the details are so fully given, and in a journal of such high standing, that we have thought some of our readers may feel inclined to try the experiment and report results.

Hybridization Proper.

Whatever there may be in the above, there is no doubt about the experiment in our neighboring town of Oakland, in hybridizating the potato, in the ordinary manner of such a process, as described in a late number of the Oakland *Transcript:*

"Mr. Pryall, who lives out on Broadway extension, has recently been making some very beautiful horticultural experiments, all of which promise to culminate most successfully. One of these experiments, and the only one which we shall mention now, was undertaken for the purpose of obtaining a new variety of potatoes, by a system of hybridizing. Some of the potatoes raised by this method have a most beautiful, clear appearance, and we are assured that the flavor is vastly improved. The varieties experimented upon were the peach-blow and pinkeye, both of which are highly valued as articles of food. The product of these two varieties partakes of the character of both, containing, as it does, the best qualities of the parent kind. In fact, it is an improvement on either. The way in which the specimens exhibited to us were obtained was this: Both varieties were planted on the same plat of ground, but in different rows. After the potato vines commence to bloom, the pollen or fecundating dust of the pinkeye is gathered and sprinkled on the blossoms of the peach-blow, which is then covered until the two qualities are thoroughly united. The result is, that the potato is a sort of a mongrel, but superior to either of the species from which it is propagated."

New Tomatoes.—The currant tomato is noticed as among the new garden vegetables recently introduced into the New York market. It is said to be the most ornamental of all the varieties of this vegetable. It is a veritable tomato, and produces its fruit upon *racemes* or strings, like currants, from which fact it takes its name. The fruit is of a bright red color, about the size of the common cherry currant; and by reason of the peculiarity named, it is very interesting and ornamental.

Still another tomato is described among the fruit novelties of 1870, called the Trophy tomato. The *Practical Farmer* says: "It is the result of twenty-three years propagation and selection, which will no doubt secure permanency in its good properties, whatever they may be. Single specimens have weighed one and a half pounds, besides being very early, well flavored and well shaped; and in proportion of seed and water are said to be singularly small. The fruit cuts solid, like a round of beef."

Fungi on Orange Trees.—A disease has recently made its appearance on the orange tree in some of the Southern States. The leaves are attacked with a species of fungus, and the fruit is also discolored. The disease appears to be akin to the "mildew" on the grape, and it is recommended that it should be checked in the same way—by the use of sulphur.

Steam Plowing at the South.—Mr. Effingham Lawrence, of Louisiana, having used the steam plow for two years, concludes that it saves nearly one-half the labor in plowing, and, owing to the deeper working of the ground, the crop is nearly 50 per cent. better than on ground tilled in the ordinary way. He thinks steam plows will do much towards solving the labor question in the South.

What I Know of Farming—No. 14.

Plowing—Deep or Shallow.

Rules absolutely without exception are rare; and they who imagine that I insist on plowing all lands deeply are wrong; for I hold that much land should never be plowed at all. In fact, I have seen in my life nearly as large an area that ought not as I have that ought to be plowed; by which I mean that half the land I have seen may serve mankind better if devoted to timber than if subjected to tillage. I personally know farmers who would thrive far better if they tilled but half the area they do, bestowing on this all the labor and fertilizers they spread over the whole, even though they threw the residue into common and left it there. I judge that a majority of our farmers could increase the recompense of their toil by cultivating fewer acres than they now do.

Nor do I deny that there are soils which it is not advisable to plow deeply. Prof. Mapes told me he had seen tracts in West Jersey whereof the soil was but eight inches deep, resting on a stratum of copperas (sulphate of iron), which, being upturned by the plow and mingled with soil, poisoned the crops planted thereon. And I saw, last summer, on the intervale of New river, in the western part of Old Virginia, many acres of corn which were thrifty and luxuriant in spite of shallow plowing and intense drouth, because the rich, black loam which had there been deposited by semi-annual inundations, until its depth ranged from two to twenty feet, was so inviting and permeable that the corn-roots ran *below* the bottom of the furrow about as readily as above that line. I do not doubt that there are many millions of acres of such land that would produce tolerably, and sometimes bounteously, though simply scratched over by a brush harrow and never plowed at all. In the infancy of our race, when there were few mouths to fill and when farming implements were very rude and ineffective, cultivation was all but confined to these facile strips and patches, so that the utility, the need of deep tillage, was not apparent. And yet, we know that crops often failed utterly in those days, plunging whole nations into the miseries of famine.

The primitive plow was a forked stick or tree-top, whereof one prong formed the coulter, the other and longer the beam; and he who first sharpened the coulter-prong with a stone hatchet was the Whitney or McCormick of his day. The plow in common use to-day in Spain and Turkey is an improvement on this, for it has an iron point; still, it is a miserable tool. When, at five years old, I first rode the horse which drew my father's plow in furrowing for or cultivating his corn, it had an iron coulter and an iron share; but it was mainly composed of wood. In the hard, rocky soil of New Hampshire, as full of boulders and pebbles as a Christmas pudding is of plums, plowing with such an implement was a sorry business at best. My father hitched eight oxen and a horse to his plow when he broke up pebbly green-sward, and found an acre of it a very good day's work. I hardly need add that subsoiling was out of the question, and that six inches was the average depth of his furrow.

I judge that the best steel plows now in use do twice the execution that his did with a like expenditure of power—that we can, with equal power, plow twelve inches as easily and rapidly as he plowed six. Ought we to do it? Will it pay?

I first farmed for myself in 1845 on a plat of eight acres, on what was then the open country skirting the East river, nearly abreast the lower point of Blackwell's Island, near Fiftieth street, on a little indentation of the shore known as Turtle Bay. None of the avenues east of Third were then opened above Thirtieth street; and the neighborhood, though now perforated by streets and covered with houses, was as rural and secluded as heart could wish. One fine spring morning, a neighbor called and offered to plow for $5 my acre of tillage not cut up by rows of box and other shrubs; and I told him to go ahead. I came home next evening, just as he was finishing the job, which I contemplated most ruefully. His plow was a pocket edition; his team a single horse; his furrows, at most, five inches deep. I paid him, but told him plainly that I would have preferred to give the money for nothing. He insisted that he had plowed for me as he plowed for others all around me. "I will tell you," I rejoined, "exactly how this will work. Throughout the spring and early summer, we shall have frequent rains and moderate heat; thus far, my crops will do well. But then will come hot weeks, with little or no rain; and they will dry up this shallow soil and everything planted thereon."

The result signally justified my prediction. We had frequent rains and cloudy, mild weather, till the 1st of July, when the clouds vanished, the sun came out intensely hot, and we had scarcely a sprinkle till the 1st of September, by which time my corn and potatoes had about given up the ghost. Like the seed which fell on stony ground in the Parable of the Sower, that which I planted had withered away, "because there was no root;" and my prospect for a harvest was utterly blighted, where, with twelve inches of loose, fertile, well pulverized earth at their roots, my crops would have been, at least, respectable. When I became once more a farmer in a small way on my present place, I had not forgotten the lesson, and I tried to have plowed deeply and thoroughly so much land as I had plowed at all. My first summer here (1853) was a very dry one, and crops failed in consequence around me and all over the country; yet mine were at least fair; and I was largely indebted for them to relatively deep plowing. I have since suffered from frost (on my low land), from the rotting of seed in the ground, from the ravages of insects, etc.; but never by drouth; and I am entirely confident that deep plowing has done me excellent service. My only trouble has been to get it done; for there are apt to be reasons—(haste, lateness in the season, etc.)—for plowing shallowly for "just this time," with full intent to do henceforth better.

I close this paper with a statement made to me by an intelligent British farmer living at Maidstone, south of England. He said:

"A few years ago there came into my hands a field of twelve acres, which had been an orchard; but the trees were hopelessly in their dotage. They must be cut down; then their roots must be grubbed out; so I resolved to make a clean job of it, and give the field a thorough trenching. Choosing a time in autumn or early winter when labor was abundant and cheap, I had it turned over three spits (27 inches) deep; the first being merely reversed; the second reversed and placed near the bottom; the third being reversed and placed above the second. The soil was strong and deep, as that of an orchard should be; I planted the field to garden peas, and my first picking was very abundant. About the time that peas usually begin to wither and die, the roots of mine struck the rich soil which had been the first stratum, but was now the second, and at once the stalks evinced a new life—threw out new blossoms, which were followed by pods; and so kept on blossoming and forming peas for weeks, until the first crop far more than paid the cost of trenching and cultivation."

Thus far, my English friend. Who will this year try a patch of peas on a plat made rich and mellow for a depth of at least two feet, and frequently moistened in summer by some rude kind of irrigation? —*Horace Greeley.*

Notices to Correspondents.

G. S., of Petaluma, thinks that the "robin redbreast of Europe" is identical with the "robin" of California, and asks whether such is not the fact. In answer, we would say that the common robin of this country is quite a different bird from the robin of the Eastern continent. It is possible that the robin which is occasionally met with in Petaluma may be a wanderer from Asia, across Behring's Straits; if so, the fact will be new to naturalists, and will be one of considerable interest. If our correspondent will send one to our address—dead or alive—we will answer his query definitely, so far as the specimen sent is concerned. We owe an apology to our correspondent for the delay in replying to his query.

STIFLE.—As the query of our correspondent, "C. E. S.," as to the best method of curing "stifle," has not been answered by any of our other correspondents, we shall next week give the method provided in the case to which "C. E. S." refers, and, perhaps, some others, as No. 3 of our series of "Diseases of Horses." We propose to make that series of articles a feature in our agricultural department, and should be pleased to receive hints or communications from any of our readers who may be able to communicate valuable facts on a subject of so universal interest.

L. L., of San José, proposes to try the experiment of raising opium, and asks several questions about its culture. He will find all his questions fully answered in the SCIENTIFIC PRESS of February 12th and 19th and April 2d.

S. H. H., on "Grape Growing near the Coast Range," will appear next week. Our readers will find, therein, some valuable hints with reference to the ravages of the "mildew" upon the grape and vine.

R. W. T., Nevada.—You will find the answer to your query under the "Notices of Recent Patents" in our issue of April 9th.

OUR pioneer agent, William H. Murray, who has long traveled for the SCIENTIFIC PRESS, is now on his way to Idaho, through the State of Nevada. We recommend him as one of the best of travelers, and bespeak for him many new friends in the districts he is about to visit for the first time. Our distant friends may know him by his long gear, dark hair and eyes, sharp features and dark complexion.

The Martin Patent Engine.

This engine is said to be rapidly coming into use, and receiving flattering testimonials as to its value. It is exceedingly simple, cheap and apparently durable, and admits of very extensive application, since it can be used, with a few modifications, as a steam engine, a hydraulic engine, an air or a force-pump. These engines require little attention after setting up, and will run day in and day out without being touched, except for oiling. They are used as force-pumps by the White Pine Water Company, and these raise the water 670 feet with one lift, giving "the most perfect satisfaction." They are used at the water works of the State Prison at San Quentin, and of their effectiveness, Gov. Haight and Lieut. Gov. Holden, as Directors of the institution, give the strongest testimony. They are to be used at the Amador mine, and, in fact, orders are coming in from various other places. We find the following in the Sacramento *Union*, from its Plumas county correspondent: "A Martin hydraulic engine of seventy-horse power has just been put up for the Indian Valley Mining Company, and, I am glad to say, proves an eminent success, and will, through the numerous advantages it offers where a high pressure of water can be obtained, be of incalculable benefit to the mining interest of this coast, if it does not revolutionize it altogether through the cheapness it will bring about in the price of reduction." This machine is a California invention, and one of the best. Any one in the city wishing to see it in operation, can easily satisfy himself by calling on H. B. Martin, No. 13 Fremont street.

◆

THE Liverpool metal market is still rather unsettled, according to Messrs. J. Lewis & Son's report. The amount of copper stock at Liverpool and Swansea is estimated at 16,494 tons fine. The market is, however, inactive, holders being firm and smelters refusing to purchase, having previously supplied their wants. Copper is quoted at $3.25 per unit. Antimony has improved and regulus is quoted at $360 per ton. Tin is firm. Spanish quicksilver was not to be obtained for shipment; nominal price, $34.25 per flask. Spanish manganese is still quoted at $17.50, and Californian at $12.50 for 70 per cent.

◆

STATE GEOLOGICAL SURVEY.—On Wednesday a party under Mr. Hoffman and Mr. Greenleaf started off to go down the San Joaquin Valley to Visalia and over the Sierras to Owens Valley and the Owens river region up to Mono Lake, to get up the topography and geology of these districts. Very soon another party will start out for the mountains to investigate the mines, under Mr. Bowman, and Mr. Wackenreuder will complete the topographical work on the Sierras from Plumas to Tuolumne counties.

◆

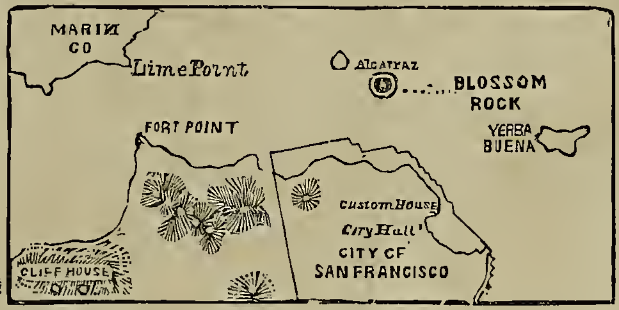
SPRINGS IN STEAM HAMMERS.—A new English three-ton steam hammer has springs composed of layers of wrought-iron plates, between the cylinder and the legs, to partly absorb the force of the blows and prevent breakage, which had before been frequent in hammers of that description. The device is said to be completely successful.

Blossom Rock.

The grand explosion is to come off to-day (Saturday) at half past one o'clock, and will undoubtedly be witnessed by thousands from the hilltops. This rock has long been an obstacle to our commerce, situated, as it is, directly in the course which vessels are often obliged to take and being covered, at low tide, with five feet of water. Moreover, the currents are such and so strong that if a vessel gets near the rock it can escape only by a miracle, almost, from striking it.

Government has attempted several times to remove the rock by exploding torpedoes on it, but without success; and last year the Department advertised for proposals for its removal, appropriating therefor the sum of $75,000, in currency. Col. A. W. von Schmidt, well known as a most successful engineer and the constructor of the Dry Dock and other important works, happened to suggest a plan, when in Washington, for destroying this obstacle, and was urged to elaborate this and apply for the contract, which he obtained. Of the method of working, several accounts have already appeared, all of them, however, more or less incorrect. We hope hereafter to give a full description, with illustrations; but at present the Department is unwilling to have anything of the kind published. We may repeat, however, what has been before stated, that the general plan is to excavate the center, making a large cavity and leaving a crust, which is finally removed by being blown up with powder when the remainder of the work has been completed.

As the public generally appear to have rather indefinite ideas as to the location of Blossom Rock, we give a rough diagram denoting its relative position. It lies north of Telegraph Hill, and east of the Golden Gate. It is to be hoped that on Saturday night this dangerous obstacle to commerce will have been effectually removed. It is said that 23 tons of powder, manufactured by the California Powder Co., which are inclosed in sheet-iron cylinders and barrels, will be used. These will be fired by means of a galvanic battery, from a vessel anchored a considerable distance off. Mr. Valentine, who had charge of the cannon at the Musical Festival, will take charge of this department here.



◆

ODD FELLOWS' PIC NIC.—The Odd Fellows of this city will celebrate the 51st anniversary of the establishment of the Order by a pic nic excursion to Saucelito, on Tuesday next. The fine steamer "Capital" will be put on the route on that day, in addition to the company's regular steamer "Princess." A fine time may be expected. Tickets for the round trip $1; children half price.

◆

MINES AND MILLS OF COLORADO.—In Mr. Paul's concluding letter two errors occurred. In regard to the mills at Central City the number of stamps should be from ten to eighty, instead of thirty; and in the milling loss, it should read that "80 per cent. goes down the creek."

◆

COAL DISCOVERY IN INDIA.—While boring for water at Midnapoor, Bengal, a bed of coal was struck. Further explorations will be carried on.

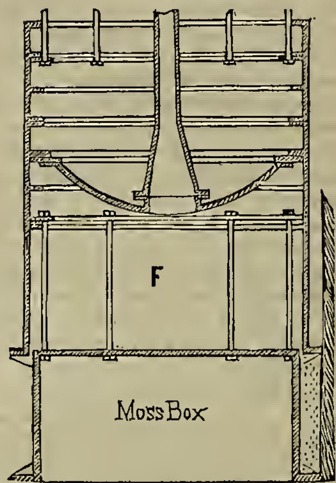
Boring Large Shafts.

[CONTINUED FROM PAGE 267.]

Tubbing the Shafts.

This is accomplished by lowering into the pit a metallic cylinder which rests on a foundation cut at the bottom. The cylinder, F, is made smaller than the pit, and the space between it and the walls filled in with concrete. The concrete used was made of one-fourth Vassy or Rsppe cement, one-fourth hydraulic lime, one-fourth sand, and one-fourth powdered trass.

The tubbing is formed in sections, made of cast iron, which are added one after another at the top, as the cylinder sinks, and bolted together. The outer surface is quite smooth, but the inner is strengthened by horizontal ribs. The joints are made tight by a lead packing. To secure a tight packing at the bottom of the shaft a "moss box" is used. This is merely a section with a flange at the bottom projecting outward. The bottom of the tubbing has a similar flange. The space between the two flanges are filled with moss, held in place by a net drawn tightly around it. The whole is suspended by iron rods, as shown in figure F, as it is lowered, but when the bottom is reached, the whole weight of the tubbing presses on the moss, by means of the upper flange, and it is compressed till it completely fills the space and forms a water-tight packing.



The operation of lowering the tubbing is easily performed. Upon the lower edge of the last section but one of the cylinder, a hemi-spherical shaped bottom is attached, by bolts and flanges. This has a central opening into a cast iron column, called the equilibrium column, rising within the tubbing, and at distances of about 25 feet pierced with holes, 0.4-inch in diameter, for the purpose of admitting water into the tubbing as fast as the latter is sunk into the pit. These holes are closed by screws, and as the tubbing is lowered, the water rises around it and within the column, until enough is displaced to cause the tubbing to float. By removing some of the screws closing the holes, water is admitted into the interior, and the cylinder is made to sink. The apparatus is lowered by means of six suspending iron rods, terminated in long screws. The rods are made up of lengths, which are added as the tubbing descends. When this was finally in place it was allowed to fill with water for two days, in order to gradually obtain the maximum compression of the moss. The descent in this case lasted 40 days.

In concreting the first pit three sets of men were employed 25 days, and 10,031 cubic feet of material were used. The concrete was allowed to harden one month. Lastly, the water was pumped out, and the false bottom and equilibrium column removed. The moss box was found in good condition. The second shaft was finished in a similar manner.

Conclusion.

The entire expense of sinking the first shaft was about $51,000; of the second,

$88,090. The work lasted 3½ years. "The successful boring of these shafts proves the advantages of the system *a niveau plein*, viz.: complete insulation of the watered strata; great strength of the lining of the shaft; avoidance in great measure of the slides and broken strata caused by pumping out the water in the old method, which produced excavations in the sides; considerable reduction of expense; economy of time; and possibility of traversing all kinds of strata of whatever thickness or description."

◆

Separating Gold and Silver by Chlorine Gas.

This process, invented by Mr. F. B. Miller, seems to have been tested on a large scale with satisfactory results. It consists in melting the bullion in a crucible and passing into this, through a pipe in the cover, chlorine gas, as long as this is absorbed by the silver, which is thus converted into chloride of silver. This can then be poured off, in a fused condition, from the gold, which solidifies more quickly on cooling. The chloride of silver can be reduced in several ways. One method, devised by Dr. Leibriss, is highly spoken of, and consists in reducing by plates of zinc combined with slabs of chloride into a galvanic arrangement. In twenty-four hours the chloride is completely reduced to the state of spongy silver. No acid is required, and the zinc consumed is only 25 per cent. of the chloride reduced.

The experiments at the Sydney mint, Australia, were so favorable that the process is to be introduced there. Two thousand ounces of gold were readily refined in five hours with three melting furnaces, 98 per cent. of the gold being delivered ready for coinage the same day. The gold can easily be obtained 995 fine. The ultimate loss in gold is given as 0.019 per cent.; of silver, 0.240 per cent. The cost of refining, inclusive of this, but exclusive of "rent of premises and expenditure," is stated as five farthings (1¼ cts.) per ounce.

◆

The Trade of the Pacific.—Henry G. Langley, the well-known publisher of the San Francisco and the Pacific Coast Directories, will issue about the first of June the first number of "The Trade of the Pacific," a quarterly advertising journal devoted to the interests of the Pacific coast. This is intended as a vehicle for the dissemination of correct and important information connected with the resources of the coast and a reliable medium of communication between manufacturers and traders here and in adjacent foreign countries. It will be in quarto form, will contain matter of import to all branches of business, besides its advertising patronage, and will be regularly forwarded, *free*, to all merchants, traders, mill-owners and superintendents in all States and countries of the Pacific Ocean. That it will be a success and get a large support is guaranteed by the reputation of the enterprising proprietor. For the insertion of advertisements, at moderate terms, address Henry G. Langley, 612 Clay street, San Francisco.

◆

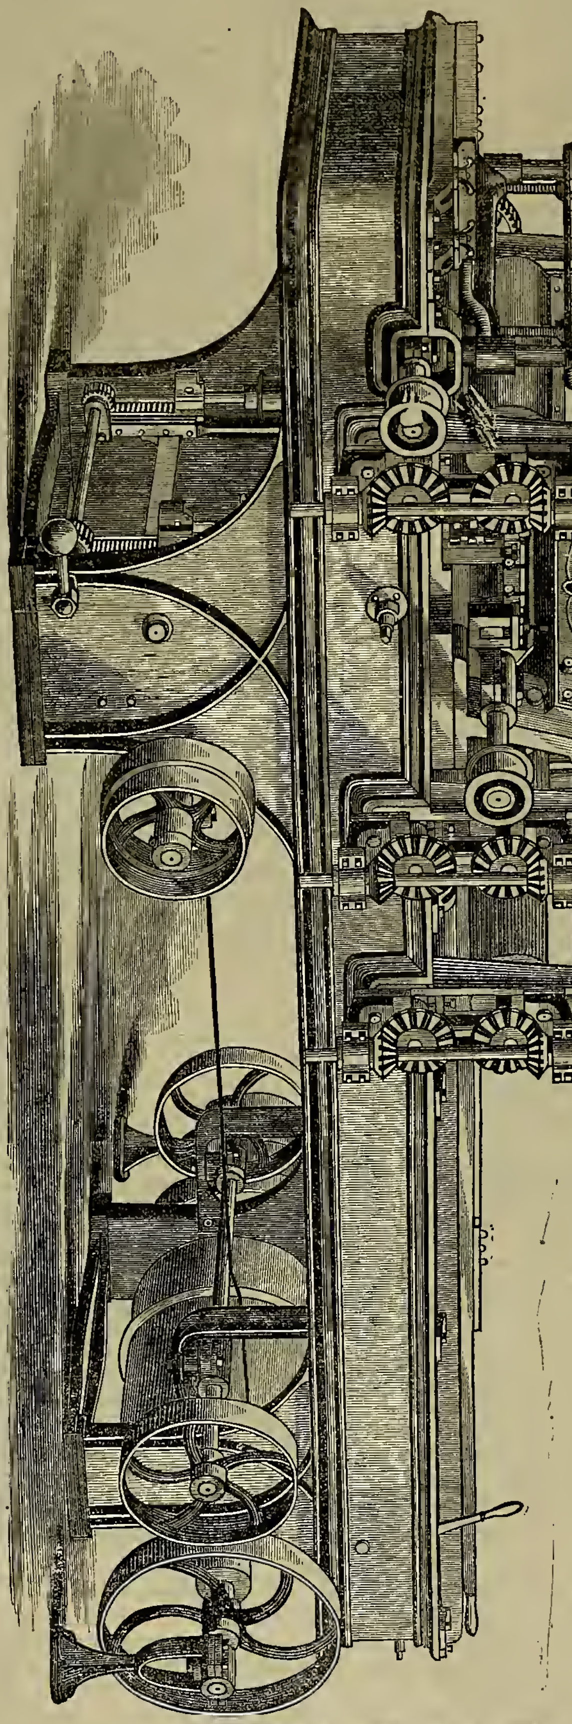
Tunnel at Detroit.—It is proposed to tunnel under the Detroit river, in order to accommodate the traffic on the Michigan Central and Great Western Railroads. The tunnel will extend from Detroit to Windsor, and will be one and three-fifths miles long. It is said that there will be two tunnels, each eighteen and one-half feet in diameter, and each with a single track, instead of one large tunnel with a double track. The grade is one in fifty each side of the river with a thousand feet of level line under the river. Estimated total cost, $2,650,000; time necessary, two years.

◆

Coal Mining in France.—M. de Simony, in a recent work on the carboniferous basin of the Loire, states that in this district, which yields a quarter of the coal in France, there are 51 mines which together produce over 3,000,000 tons annually.

Large Planer and Matcher.

There is a large variety of Woodworth planers. They are extensively used, and, as an illustration of a well-known and standard article, the engraving here given will be viewed with interest by those who are both familiar and unfamiliar with the operation of the tool represented. The principle in them all is the same—that of the revolving horizontal cylinder, upon which the cutters are fastened. The Woodworth planer is now known by this feature alone, in contradistinction from the "Daniels planer," where the knives are fastened to a disk which revolves on an upright arbor.



THE WOODWORTH PLANER AND MATCHER.

The above is a good representation of a heavy planer and matcher (single or double cylinder), which has been introduced the past year into this market by Berry & Place, of this city.

These machines are built of entirely new patterns, and are peculiarly adapted for heavy lumber mills. They have Richardson's patent extension feed gears, which are claimed as the most simple and durable of any expansion gears, and by which the power is applied directly to the rolls; patent self-oiling boxes; wrought-iron cylinder heads with cast-steel arbors, the upper one having three and the lower two knives, and will surface twenty-six inches wide; gun-metal matcher heads, capable of grooving sixteen inches wide, or planing the thickest lumber.

This machine has also the improved patent matcher attachment, a simple and complete device attached to the lower part of the matcher arbors, so arranged that one-half turn of a crank will lower the arbors below the bed-plate, and a reverse motion will raise them. In this operation the connection is not broken with the rod at the end of the machine for adjusting the matcher heads to different widths stuff, *a point of great advantage.* The machine has six heavy feed rolls, and weighs 8,700 pounds.

Berry & Place, general dealers in wood-working machines, have one of these planers on exhibition at their warerooms, 112 California street. They have sold several of these large machines to go to the mills around Puget Sound, where the heaviest machines are required for dressing lumber, and we are assured they have given the best satisfaction.

◆

Hercules Powder.

Hercules powder is a new explosive manufactured by the California Powder Works. It is a mixture of carbon, sulphur and nitre, reduced to a fine powder and incorporated with nitro-glycerine so as to form a stiff paste, in which condition it is safe to handle and transport. It will not explode on contact with fire, but burns quietly, and it may be hammered on hard wood without danger of explosion. It will explode, however, on being hammered on an anvil, or on being ignited in a strong vessel with no aperture for the escape of the gases. In use it is exploded by means of a copper cap, heavily charged with fulminate of mercury or other quick explosive, placed on the end of the fuse and inserted into the powder. The holes may be loaded with cartridges or with the paste therein in pieces, and tamped with a wooden rod. In blasting under water, great care should be taken to keep the cap dry, as on this depends the success of the blast. Like other nitro-glycerine compounds, Hercules powder freezes at about 42 degrees Fah., and above 200 degrees decomposes and gives out noxious fumes. If frozen it should be thawed out gradually in a warm room.

The object aimed at in this composition is to produce a powder which will combine the quickness of any of the recently-invented explosives, and the lifting force of the best blasting powder. The company feel sure they have attained this, and for its successful use refer, among others, to the following localities: R. L. Crary, Sucker Flat, Yuba county; Keystone mine, Downieville; Church M. Co., El Dorado county; J. O'Brien, Smartsville; L. L. Robinson, Hunter's Valley; Hope M. Co., Silver City; the Sutro Tunnel, the mines on the Fremont Grant, and also to other mines in Mariposa county and in Colorado and Nevada. It can be obtained in bulk or in any sized cartridges, by ordering directly from the office, 314 California street, San Francisco, or from any of the agents of the company.

◆

The Studebaker Wagons.—The general agents for this wagon are Messrs. Ames & Woolverton, who are connected with the Kimball Wagon Factory of this city. These gentlemen have an agency also for the sale of the Strayer grain drill and Oliver's chilled plow. Concerning the firm, we find the following in the *Register*, published at South Bend, Indiana, whence the gentlemen hail:

Messrs. Ames & Woolverton will operate both in California and Oregon, and we predict for them an extensive trade. They are young men of undoubted integrity, excellent business qualifications, and none in this community stand higher than they do. They also have the advantage of being personally acquainted with the manufacturers of the articles they sell—articles which have a reputation second to none whenever used—and can conscientiously recommend them. South Bend has already furnished California many of her best business men—the Crockers of the Pacific Railroad, Gen. J. F. Miller, etc.—and she now sends two others who will not be long in making their mark in the business circles of San Francisco. Success attend them.

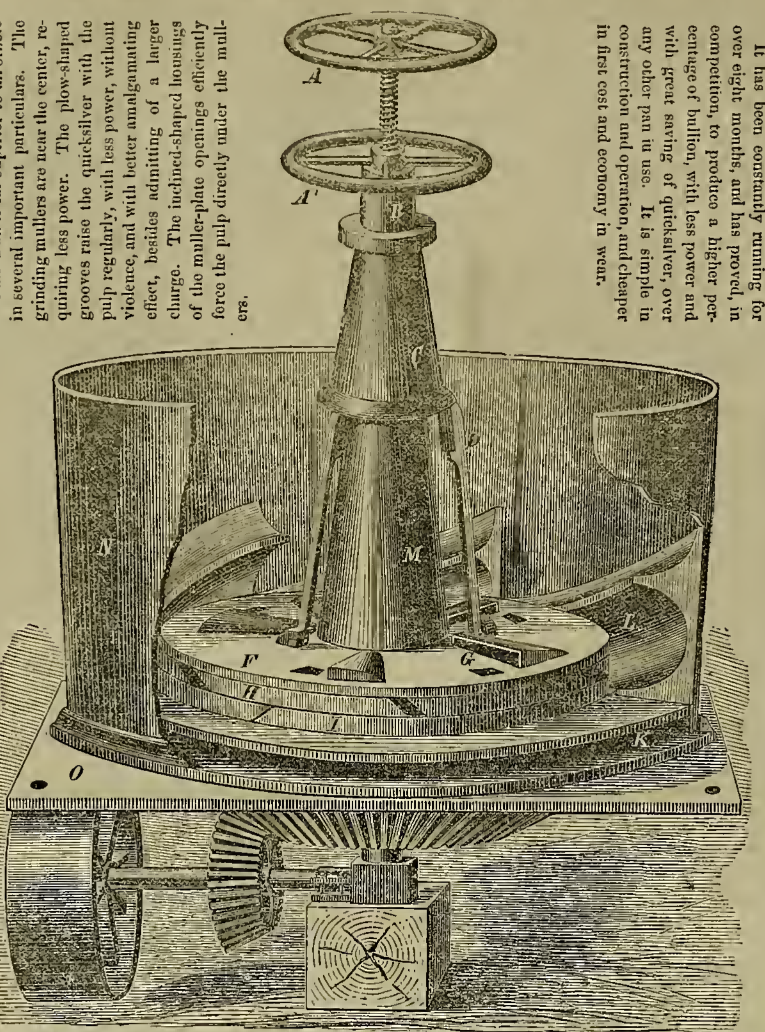
STEVENSON'S PATENT MOULD BOARD AMALGAMATING PAN.

This Pan is far superior to all others in several important particulars. The grinding mullers are near the center, requiring less power. The plow-shaped grooves raise the quicksilver with the pulp regularly, with less power, without violence, and with better amalgamating effect, besides admitting of a larger charge. The inclined-shaped housings of the muller-plate openings efficiently force the pulp directly under the mullers.

It has been constantly running for over eight months, and has proved, in competition, to produce a higher percentage of bullion, with less power and with great saving of quicksilver, over any other pan in use. It is simple in construction and operation, and cheaper in first cost and economy in wear.



Manufactured at the Golden State Iron Works (Co-operative), 19 First street, S. F.,

Where it can be examined and further particulars be learned; or persons may apply to the inventor and patentee, Mr. C. C. STEVENSON, at the Douglas Mine, Gold Hill, State of Nevada, where the Pans have long been in constant operation.

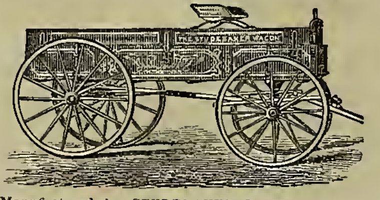
The Celebrated Studebaker Wagon,



Manufactured by STUDEBAKER BROS. MANUFACTURING CO., South Bend, Indiana. WAGON DEALERS, there are nine reasons why you should buy the above Wagon:

First.—They are made of the best selected INDIANA TIMBER, thoroughly seasoned under cover. Second—They are made by experienced mechanics. Third—The lightest running and most durable Wagon in the market. Fourth—Their Thimble Skeins never break, while all others do. Fifth—Most uniform and best proportioned Wagon in the market; any part of one will fit another, while other makes will not. Sixth—The only Wagon in which the Slope Shoulder Spok is used; hence they have the best Wheel, which is actually the foundation of the Wagon, and should be carefully examined by persons buying. Seventh—They are sold only by responsible parties, and every Wagon is warranted to give entire satisfaction. Eighth—Because Teamsters will tell you they are the best Wagons, for all purposes, on the road. Ninth—Last, but not least, Studebaker Brothers are practical men, attend to their business personally, and do not entrust it entirely to foremen, as is generally the case in large factories; hence the superiority of their work over all others.

Sold by COPELAND & DEFREES, K street, between Seventh and Eighth, SACRAMENTO, CAL. ☞ Pioneer Agents for the Pacific Coast. 15v20-3m

DR. ABORN,

Oculist, Aurist,
AND
CATARRH, THROAT
AND
Lung Physician.

No. 22 KEARNY STREET,
SAN FRANCISCO, CAL.

Testimonials from Well-known Citizens of California as evidence of his success.

Card from Charles N. Fox, Esq., of the firm of Campbell, Fox & Campbell, Attorneys, 528 California Street.

I have for many months suffered from Catarrh, accompanied with unpleasant sensations and sounds in the ears. Recently I found my hearing impaired, and at once applied to Dr. Aborn, No. 22 Kearny street, San Francisco. He improved my hearing almost instantaneously, and now, after being under his care six days only, I feel as if entirely cured, and my hearing is restored. CHARLES N. FOX.
San Francisco (Cal.), Jan, 10, 1870.

Card from S. O. Houghton, Esq., Attorney at Law.

I have been afflicted with severe nasal Catarrh for two years, which a few months since extended to my throat, producing a distressing cough, and seriously impairing my health generally. I have been under treatment by Dr. Aborn, at 22 Kearny street, San Francisco, for about three weeks, and have been already greatly relieved—my cough has almost disappeared and my health greatly improved. By one application, Dr. Aborn relieved me of a very severe neuralgic pain, and with four applications it was entirely cured. S. O. HOUGHTON.
San Jose (Cal,), Nov. 22, 1869.

From Hon. Jas. A. Johnson, M. C., California.

To whom it may Concern.—Having been a sufferer with Catarrh and a severe bronchial affection for more than seven years, and having found great relief by submitting myself to Dr. Aborn's treatment for a few days only, I take pleasure in saying Dr. Aborn, with his new and improved instruments for local applications to the lungs, air passages, eyes and ears, should encourage all who are affected in those parts to cherish a lively hope that they may find quick and permanent relief. Very truly, JAMES A. JOHNSON, M. C., California.

A Wonderful Cure.

Having been afflicted for over twenty years with a disease in the left nostril, which has been called by different names—cancer, scrofula and ozena—different physicians have tried their skill in attempting its cure, but without success. It has rendered me incapable of labor for the last two years. Since the beginning of June last I have been in the Sacramento hospital reduced to a mere skeleton. On the 23d of November I left the hospital, and since the 26th have been under the treatment of Dr. Aborn in this city, and the disease is already nearly cured, and my strength and general health very much improved, and I have full confidence of a perfect cure. Already I have gained many pounds in weight, and look and feel like another person. The success of Dr. Aborn's treatment in my case should be sufficient to encourage all who have chronic diseases to make another trial for that good prize—health.
WILLIAM BEARDSLEE.
Pacific House, San Francisco, Dec. 13, 1869.

Another Remarkable Cure.

For the benefit of the afflicted and as an act of justice to the skill of Dr. Aborn, I make the following statement: For about two years I was seriously afflicted with a bronchial affection. I had a distressing cough, difficulty of breathing, expectoration, night sweats, and was losing flesh very rapidly. I was treated by five physicians without any benefit, but continued to grow worse, and was finally advised by them to leave the city, as in their opinions I could not be cured in this climate; but my business relations were such as to preclude a change of climate, although my health was declining so fast that I could not have lived long without relief. Two months ago, when Dr. Aborn arrived, I read his publications and the testimonials of his remarkable cures, which led me to believe that there must be merit in his treatment. So I placed myself under his care, and it is with great pleasure that I am able to say that he has cured me of those distressing and dangerous bronchial affections; also, the night sweats, cough, etc. I was unable to attend to business since April last, until after being under Dr. Aborn's treatment for one week. My improvement was so rapid that in one week's time I was able to resume my business, and I have continued to gain ever since so rapidly that even my friends are surprised at the remarkable results of his treatment.
VINCENT MONATTI,
Corner of Dupont and Green streets.
San Francisco, Dec. 25, 1869. 7v20-3m

GIANT CEMENT.
GIANT CEMENT.

A most extraordinary and universally needed article for mending Furniture, Crockery, Glassware, Marble, Meerschaum Pipes, Ornaments, etc.; also splicing Leather Belting and patching Boots and Shoes. This Cement possesses extraordinary merit, and is in every way a first-class article. Every can is its own testimonial. Also, Miners' Rubber Cement, for mending Rubber Boots, Shoes, Belting, Coats, and Hose without stitching! Easily applied, never failing, and perfectly waterproof. Both Cements are put up in tin cans only, with full directions. Take no other. Giant Cement and Miners' Rubber Cement are kept by Druggists and Dealers throughout the country. Country Dealers can be supplied by ordering from any house here or in Sacramento with whom they deal, or by sending direct to us. Send for Agents' Circulars and Price List to Giant Cement Manufacturing Co, 419 Washington street, San Francisco

Well-Borers and Water Companies.

M. PRAG IS NOW PREPARED TO MANUFACTURE Hydraulic and Artesian Well Pipes in the best workmanlike manner, and at the lowest market rates. Having made large additions to my stock of machinery for that branch of business I am prepared to fill all orders with dispatch, and guarantee entire satisfaction. I also manufacture Mississippi Stoves, of the latest improved patterns, for vessels of all classes. Also, Ship Plumbing done.
M. PRAG.
3v18 ly Stove Store, No. 125 Clay Street, below Davis

The Eden Dale Company, for Tropical Fruit Raising.

The Eden Dale Company, of San Francisco, which recently filed its certificate of incorporation, has now issned a prospectus, from which we learn that it is the design of the Association to engage in the business of raising semi-tropical frnits, and snch other fruits and prodncts as may he fonnd hest adapted to the climate and soil in the sonthern part of the State; and to that end they will huy, sell, lease or rent land and its appnrtenances. The amount of capital stock, $360,000. The officers of the Associatiou are: Henry Gihhons, President; John Archihald, Vice President; W. J. Taylor, Secretary; Treasurer, the London and San Francisco Bank; Directors: H. Gihhons, J. Archihald, A. Giorgiani, R. T. Rundle and J. E. Eaton.

We understand that all kinds of tropical fruits will he experimented with, and the enterprise will he conducted on a large scale. An undertaking of this kind, properly conducted, as we presnme this will he, cannot fail to prove of great importance in this State. We shall prohahly have occasion to refer to this enterprise, more fully, at another time.

Academy of Sciences.

At the regular meeting on the 18th inst., several specimens of fossils were presented to the cabinet of the Society, also a collection of American ferns and a number of scientific works. The Academy decided to memorialize Congress in favor of an appropriation of $100,000 forCapt. Hall's proposed expedition to the Polar Sea.

Our Coal Formation.

Prof. Whitney corrected some statements which have heen made hy Mr. Rohert Brown, of Edinhurgh, to the effect that the coal of this State is inferior to that of British Columhia, and that we might expect to depend on that province for our future supplies; also, that the coal heds of British Columhia belonged to the true carhoniferous formation. The coals of that district were not superior to those fonnd southward, and the formation described hy Mr. Brown was not later than the cretaceous.

State Boundary—Increased Size of Lakes.

Prof. Whitney also made some remarks on the California and Oregon houndary line. This had heen accurately determined hy Maj. D. G. Major. But the California and Nevada line, although probably accurate enough for the purpose of the State Survey, mainly prosecuted to determine in which State Honey Lake Valley was situated, was not exact enough for all purposes. In this connection the Professor aaid that Goose Lake, on the northeastern line, had materially increased in volume of late. It formerly had no outlet, hut now is pouring a considerable quantity of water into Pitt river. All the lakes in this region have increased in size of late, and the Geological Survey, wheu it reached the locality, would endeavor to collect accurate information on the point.

After discussing the earthquake subject, a committee was appointed to inquire as to the hest instrument for recording earthquake phenomena.

Iodine Spring.

Mr. Hanks atated that he was engaged in the analysis of some water obtained from a apring near this city, which contained so much iodine that, without condensing, it gave a strong reaction when the proper test waa applied. A full statement of the analyais will he made to the Academy.

Experiments with Ice.—The French ateamship company, Les Messageries Impériales, having to ship a quantity of ice to Suez for the uae of its steamers in the Indian Ocean, and desiring to find the best quality for their pnrpose, auhjected 100 kilogrammes (220 pounds) of several kinds to the same conditions of temperature, with the following reaults: 1. Natural ice from Switzerland lasted 107 hours; 2. natural ice from Norway, 115 hours; 3. artificial ice made hy the Carré machine, 130 hours; 4. natural ice from Boston, Mass., 138 hours; 5. artificial ice made hy the Tellier machine, 144 honra. Artificial ice then appears to be aa solid as natural ice.

Meat Imported into England.

The retnrns with regard to English importations of cattle, sheep and hogs, and of fresh and preserved or salted meats, made hy the Board of Trade, show that during the first six months of 1869 there were imported into England as follows: 57,334 full-grown cattle; 14,784 calves; 208,176 sheep; 17,616 lamhs; 13,656 hogs and swine. Of preserved meat: 457,133 cwts. of hacon and ham; 168,747 cwts. of salt heef; 104,845 cwts. of salt pork; 37,474 cwts. of meat not described; 7,209 cwts. of heef fresh or slightly salted; 12,557 cwts. of pork fresh or slightly salted, at the computed value of four millions and a half pounds sterling—$22,500,000. Late accounts from England and Australia refer to experiments heing made with a view to perfect a system of preserving meats fresh, and there appears to he good reason to helieve they will accomplish the ohject. By one mode, the animal is made to inhale a vapor hefore having its throat cut—the kind of vapor is a secret. This appears to he the only treatment. Mr. Patrick Hayes, of Footcray, Victoria, exhihited a saddle of mutton which had heen killed ssven weeks, and was quite fresh—the vapor was the only treatment. We clip the following from the *Illustrated News:*

In our scientific column last week a paragraph was devoted to ths discussion of the principal means propounded for hringing to this country, from cheap sources ahroad, an ahundant supply of heef, mutton, and other meat; and a hope was expressed that, with the attention which is being given to the suhject, and with the issues at stake, means would soou he discovered for hringing large supplies of good meat from distant parts of the world at a moderate cost. This hope seems to he in a fair way of heing realized. On Tuesday the first of a series of sales of Australian meat, to he held on the first Tuesday of each month, took placs at the Hop and Malt Exchange, in Southwark street. The quantity of meat suhmitted was 100 tons, consisting chiefly of mutton, cured in carcass, hind-quarters, hams and rolls, packed in pure fat, which realized from 3½d. to 6d. per pound; harrels of sheeps' tongues, packed in pure fat, realized 8d. per pound; 1,000 smoked sheeps' tongues realized from 1s. to 1s. 1d. per dozen, and 300 smoked ox tongues averaged from 1s. 1d. to 1s. 2d. each; 60 cases of mutton, in tins of 7 lbs. each, fetched 6½d. per pound. Of the many forms in which Australian meat has heen introduced for consumption in this country, that which has heen found most generally satisfactory is the cooked mntton in tins supplied by Coleman & Co., St. Mary-at-hill, in the city. This meat is positively a delicacy, eaten either cold or warm. The only point necessary to be borne in mind, when serving the meat in the form of stew, is to thoroughly cook the vegetables and other ingredients hefore adding the meat. As one pound of the Australian cooked meat is equal to a pound and a half of uncooked butchers' meat, and as it is sold for 7d. or 7½d. per pound, the economy in using this article of food is considerahle.

In consequence of the great expense attending the importation of meat, the retail price in London is almost as high as it ia in San Francisco! It might be quite as dear did the hutchers' compel their customers to pay for the hones and tallow trimmed from a roast or hroil.

India Ink, or, more properly, Chinese ink, is mannfactured npon a very large scale at Shanghai. The real secret of the art of making this article is said to be in the manner of preparing the lamp-hlack, in which the Chinese excel. The agreeable odor is imparted hy a small admixture of musk and camphor. The gilded letters are first formed hy the mould, then, when the cake is dry, traced over with a solution of gelatine dissolved in water, and then the gold or copper is laid on with a fine hrush.

Sulphur Deposits—Reports come of the finding of two inexhaustible deposits of sulphur on the shores of the Red Sea, near the entrance of the Gulf of Suez. The storiea told are pretty large: a hill 600 feet high, composed entirely of sulphur which is hlasted like the rock in a common atone qnarry, etc.

New Incorporations.

The following have filed certificates of incorporation with the County Clerk, San Francisco:

Tem Piute M. Co.—Tem Piute Mining District, Lincoln county, Nevada. April 14th. Capital stock, $1,880,000, divided into 2,880 shares. Trustees: C. D. O'Sullivan, Robert J. Tohin and John O'Farrell.

Consolidated Silver Wedge M. Co.—White Pine. April 15th. Capital stock, $2,000,000, divided into 20,000 shares. Trustees: Marion J. McDonald, Louis Vesaria and Orlando H. Bogart.

Cocomongo Co.—April 18th. The ohjects are to purchase a tract of land in San Bernardino county, heing a portion of the Cocomongo Ranch, to sell, lease, rent or cultivate the same, and to use, sell or lease the water privileges thereof. The capital stock is $33,600. Directors: John Archibald, Henry Gihhons, A. Giorgiani, R. I. Rundle and Charles J. King.

Crescent G. M. Co.—Grass Valley. April 20th. Capital stock, $400,000, divided into 4,000 shares. Trustees: Geo. B. Reeve, N. K. Masten and J. W. Toard.

Sidney Brooks Tunnel and Lode Co. White Pine. April 20th. Capital stock, $500,000, divided into 10,000 shares. Trustees: L. R. Meyers, J. M. Robertson, A. W. Von Schmidt, James Bowman and D. B. Northrop.

The following have heen recorded in the Secretary of State's office, Sacramento:

Von Humboldt M. Co.—Sierra county. April 15th. Capital stock, $95,000, divided into 425 shares. Trustees: John Ramin, John R. Clow and E. H. Houghtaling.

San Francisco Real Estate Association.—April 15th. Capital stock, $80,000, divided into 2,000 shares.

Meetings, Elections, Etc.

Santa Clara & Pajaro R. R. Co.—April 18th. Directors: Peter Donahue (President), Charles Mayne (Vice President), Myles D. Sweeney (Treasurer), and Richard P. Hammond. J. L. Willcut was reëlected Secretary.

Coal Discovery in the Brazils.—According to the London *Mining Journal*, R. von Brause has discovered coal of a very good qnality in the Santa Catharina near Ararangua. The seam which crops out has been explored for a distance of some 30 miles, and found to he of an average thickness of one metre. This coal has heen thoronghly tested and analysed hy Dr. Netto, of Rio de Janeiro, and is interesting as one of the very few instances of a true coal occnrring in a recent geological formation, although in the United States and in Hanover (on the very horders of the Netherlands) two or three such occurrences are on record. The coal here alluded to is an excellent quality of gas coal.

Important Invention.—The best drink, not containing alcoholic stimulants, yet answering all the requirements, is that made by Kenyon, Gass & Co., and known as Champagne Mead. It is recommended by the medical fraternity of this city, and should be the exclusive drink of all temperance men. It contains no injurious acids. *

A Valuable Book for Inventors and Artisans.—Dewey & Co., puhlishers of the Scientific Press and Patent Agents, have just issued a neat little volume of over five hundred well executed cuts of the principal mechanical movements known. These useful representations of the various appliances of power are printed side hy side with explanatory notes, which makes the snbject clear to every reader. Such a book should he in the hands of every mechanic, and form part of every pnhlic school library. It is a handy book, and cheap enough for every farm, shop and factory. Sent to any address from the Scientific Presa office, postpaid, for $1.—*New Age.*

Extract from a letter dated St. Louis, Mo., March 1, 1870: "Messns. Dewey & Co.:—The Scientific Press has been received. Though I am a constant reader of the Scientific American and great admirer of it, I confess my surprise on discovering the Pacific slope in possession of its equal in every respect. A. J. K." (inventor).

C. Muller, optician, 205 Montgomery, stands first in his profession, and all those who suffer from defective eye-sight should apply to him. *

Continental Life Insurance Co., 302 Montgomery street, corner of Pine.

Everybody should use the Portable Gas Light sold at P. J. Philips & Co's, 550 Market street. It costs only one-fourth as much as common gas, and is equally as good. Don't fail to see it. A few county rights for sale. Don't mistake the place. *

Mason's Bread of Life, for Dyspeptics, Coughs, Colds, Asthma, Catarrh, Hoarseness, Bronchitis and Sore Throat. Price, 25 cents per hox. These lozenges are free from all dangerous properties. Compounded and put up hy Dr. J. H. Mason, 750 Howard st. 16v20-3m

Block Tin and Solder Wire, hroom wire, piano covering wire, etc., manufactured hy Joshua Gray, 437 Brannan street. 24v19-3m

Business Fortunes are often made easily, quickly and legitimately hy Patent Rights. We advise hoth sellers and purchasers to patronize reliahle agents only. Weister & Co., patent hrokers, No. 314 Bush street, San Francisco, are one of the most honest, reliahle firms in the United States. *

Photography.—For Cabinet Photographs, or Enameled Cards, of the very hest quality, you must go to the NEW YORK GALLERY, Nos. 25 and 27 Third street, San Francisco. Every picture warranted to give satisfaction.
10v18 6m B. F. Howland.

Thomas O'Neil Ornamental Glass Cutter, No. 10 Stevenson street, up stairs. Stained, Ground and Ornamental Cut Glass to order on reasonahle terms. 14v20

Microscopes for Scientific Investigation and Educational Purposes. Price list sent free. T. H. McAllister, Optician, 49 Nassau street, New York. 15v20-3m

Drs. Martinache & Smith, Oculists and Aurists, 313 Bush street, hetween Montgomery and Kearny. Hours for consultation, 12 to 3. 16v20-3m

And in accordance with law and an order of the Board of Trustees, made on the nineteenth day of March, 1870, so many shares of each parcel of said stock as may be necessary will be sold at public auction, at No. 526 California street, between Montgomery and Kearny, San Francisco, Cal., on Tuesday, the tenth day of May, 1870, at the hour of 12 o'clock M. of said day, to pay said delinquont assessment thereon, together with costs of advertising and expenses of sale.

CHAS. WELLINGTON, Secretary.

Office, 614 Merchant street, Room 26, or 526 California street, San Francisco. apr23

Mining Notices--Continued.

Alban Gold and Silver Mining Company.—

Location of Works: Virginia City, State of Nevada.

Notice is hereby given, that at a meeting of the Board of Trustees of said Company, held on the twenty-first day of March, 1870, an assessment of five (5) cents per share was levied upon the capital stock of said Company, payable immediately, in United States gold coin, to the Secretary, or to Geo. Bornwell, Esq., President of said Company, at his office, No. 432 Montgomery street, San Francisco, Cal.

Any stock upon which said assessment shall remain unpaid on Monday, the twenty-fifth day of April, 1870, shall be deemed delinquent, and will be duly advertised for sale at public auction, and unless payment shall be made before, will be sold on Saturday, the fourteenth day of May, 1870, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Trustees.

WM. B. SMITH, Secretary.

Office, 432 Montgomery street, San Francisco. m26

Alameda Coal Mining Company, San Francisco and Alameda Counties, State of California.

Notice.—There are delinquent upon the following described stock, on account of assessment levied on the sixteenth day of February, 1870, the several amounts set opposite the names of the respective shareholders, as follows:

Names.	No. Certificate.	No. Shares.	Amount.
F. T. McMahon	43	26	$7 80

PAUL'S DRY AMALGAMATING Electric Process.

A SYSTEM FREE OF DUST, that will cheaply work Gold Ores, and gather flour gold, with the same readiness as the coarser, whether free or associated with iron, copper, lead, antimony, or zinc, or all together in one matrix, and produce bullion free of any or all of the base metals

That will work Silver Ores carrying any of the base metals to a higher percentage than any system of raw amalgamation, and produce bullion not less than .950 fine.

That where silver is associated with a large percentage of lead, copper, zinc, or antimony, a certain percentage can be extracted in fine bullion—the percentage owing to ore—say 30 to 60 per cent. The residue in base metals can be taken up for smelting or roasting by concentration, at no additional expense; the bullion and concentration equaling 95 per cent. of value of ore.

[From Superintendent of Rosecrans S. M. Co.]

This is to certify, that I had worked at the Haskin & Grove Mill, Empire, 1,600 pounds of gold ore by Paul's Dry Amalgamating Process, as a test against my own working of same ore by the stamp mill, working wet, and that on comparing results the yield by the Paul Process exceeded the mill returns sixty-three per cent. per ton.

I am satisfied the Paul Process will gather the fine gold, and which it is not possible for a wet working mill to collect. AUG. GUIBOR.

☞ Pamphlets setting forth the practical working of the Process will be forwarded on receipt of any address. Parties interested in mining can gain further particulars by applying to

PARIS
Scouring and Blanket Cleaning

ESTABLISHMENT.

Blankets are cleaned in such a manner as to give them their original elasticity and gloss. Flannels of all kinds are cleansed and scoured *without fulling.* Ladies' Dresses and Wearing Apparel of all kinds are scoured and cleansed after the latest Paris style, for which Mr. Weyer's father was awarded a Medal at the Paris Fair. Silk Dresses are prepared so as to have their original gloss and appearance. Furs neatly cleaned. Curtains are washed and done up in a superior manner. Gent's Clothing of every description scoured and cleaned so as to look as well as new. Samples can be obtained at the Powell street establishment and in the branch offices, showing that my work is done in a superior and skillful manner that will suit the most fastidious. Orders called for and delivered without extra charge.

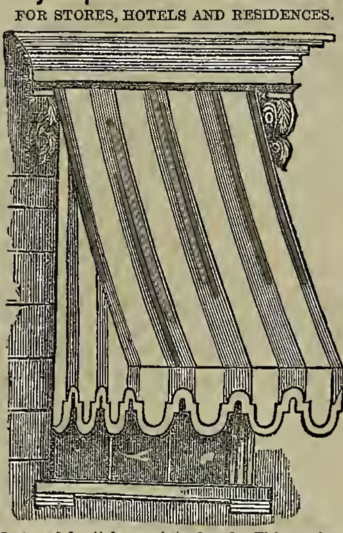
Parties in the country can have their work done well and promptly by sending their goods with orders by express.

A. WEYER, proprietor, No. 1719 Powell street; branch offices, 122 Fourth street, and 862 Folsom street. ORDER BOXES, 740 Washington street, corner Sutter and Powell, corner Fifth and Howard, corner Powell and Bush. 10v20-3m

Newly-Improved Venetian Awning,

FOR STORES, HOTELS AND RESIDENCES.

COMFORT AND ELEGANCE COMBINED.



KEEPS COOL AND SHADY

Most useful article ever introduced. This awning can be applied to the outside of any window without marring the wood-work or detracting aught from the beauty of the architecture. By the appliance of the new Patent Slide, the awning is made to come low enough to shade the longest window to the bottom, thereby protecting everything in the room from the sun, allowing a free ingress of air through the open window and giving abundance of light. Manufactured from different kinds of goods, colors and stripes, according to price and fancy, by the sole proprietors and manufacturers, J. J. WITHERS & CO., Room No. 2, up stairs, 412 Pine street, San Francisco, 11v20-3m

STEAM
FIRE-PROOF
SAFES

SANBORN'S PATENT.

Perfectly Dry in Use.

ACTUALLY FIRE-PROOF.

GET THE BEST.

The remarkable fire-proof quality of these Safes has been fully demonstrated, having been subjected to severe practical tests with the Safes of all other prominent makers, and always with complete success, preserving its papers while the contents of its competitors were destroyed. A practical man needs but to examine them to be convinced of their superiority.

☞ Burglar-proof work, welded iron and steel, Sargent & Greenleaf's Magnetic and Automatic Locks. For sale by ROSS, DEMPSTER & CO., 105, 107 and 109 California street, San Francisco.

The Equalizing Institute.

SOMETHING NEW.

THE EQUALIZER,

A GUIDE TO HEALTH.

Cures all Chronic Diseases BY VACUUM.

This treatment causes a thorough circulation of the blood throughout the system, creates new life, and reinstates perfect health. The following diseases can be cured by the above system: Paralysis, Nervous Debility, Neuralgia, Dyspepsia, Asthma, Curvature of the Spine, and other Spinal affections, Sciatica, Palsy, St. Vitus' Dance and Derangement of the Mind, and many other ailments, for particulars of which see our circular.

THE GUIDE TO HEALTH.

Testimonials.—P. Windsor, having suffered severely from four sun strokes, and in the last two years from four strokes of Paralysis and loss of speech, had recourse to the Equalizer as a treatment for same, and by means of the Equalizer was perfectly cured in the astonishing short period of four months; and as proof of the above, he can be seen at the Equalizing Institute, 650 Howard street, San Francisco.

San Francisco, April 5, 1870.

Sunday being the Sabbath Day,

THE EQUALIZER

Will be devoted to the treatment of all chronic diseases, exclusively to the poor, between the hours of nine and four o'clock, (not including paupers), free of all charges.

PROPRIETOR EQUALIZING INSTITUTE,
16v20-qy 650 Howard Street.

MARAVILLA COCOA.—*For Breakfast.*—The *Globe* says: "Various importers and manufacturers have attempted to attain a reputation for their prepared Cocoas, but we doubt whether any thorough success has been achieved until Messrs. Taylor Brothers discovered the extraordinary qualities of 'Maravilla' Cocoa. Adapting their perfect system of preparation to this finest of all species of the Theobroma they have produced an article which supersedes every other Cocoa in the market. Entire solubility, a delicate aroma, and a rare concentration of the purest elements of nutrition, distinguish the Maravilla Cocoa above all others. For homœpaths and invalids we could not recommend a more agreeable or valuable beverage." Sold in packets only by all Grocers, of whom also may be had Taylor Brothers Original Homœopathic Cocoa and Soluble Chocolate. Steam Mills—Brick Lane, London. 5v20-1y

USE

DR. S. GIRARD SMITH'S

ARAMIRACULAS

— FOR —

RHEUMATISM, GOUT AND NEURALGIA

CURES GUARANTEED.

Has cured Thousands. Has never been known
One bottle will relieve you.

OFFICE, No. 621 KEARNY STREET.

Agents Wanted in every City and Town.—Terms Liberal.

Dr. S. Girard Smith, 621 *Kearny street.*—Dear Sir It would be hard for me to say how much I thank you for the benefit your ARAMIRACULAS has conferred on me in curing my RHEUMATISM. I was confined to my bed when I first commenced to take your medicine, and after using ONE BOTTLE I am now able to work as well as before. If you know anything about having that afflictive complaint, you must know how good it is to be cured. I will state to those who may not believe in your medicine, that they can be convinced by referring them to me. Very respectfully, yours,

ENON HARRIS,
Everard's Auction Rooms, 527 Kearny street.

Statement of an old and well-known Physician who has practiced extensively in Europe and America.

We must admit that the many systems of medicine by which we have attempted to heal the human body, and rid it of disease, from the science of ALLOPATHY down to HYDROPATHY, how little they have succeeded, time has abundantly shown by their number of failures. In the cure of RHEUMATISM, GOUT and NEURALGIA, Dr. S. Girard Smith has laid aside the old way and adopted a system, so simple, that I must admit, is so natural and direct, that it recommends itself to all who are suffering with the above diseases. And it challenges and defies all the old methods of treatment. Although I have been educated through a regular course, and graduated in Europe, I must acknowledge the right, and also give due credit for personal benefit received by the new system as practiced by DR. S. GIRARD SMITH, which induces me to bear this testimony to its merits, for the benefit of suffering humanity.

A. M. HOFFMAN, M. D.,
11v20-3m New Orleans.

Ayer's Sarsaparilla,

FOR PURIFYING THE BLOOD.

The reputation this excellent medicine enjoys, is derived from its cures, many of which are truly marvellous. Inveterate cases of Scrofulous disease, where the system seemed saturated with corruption, have been purified and cured by it. Scrofulous affections and disorders, which were aggravated by the scrofulous contamination until they were painfully afflicting, have been radically cured in such great numbers in almost every section of the country, that the public scarcely need to be informed of its virtues or uses.

Scrofulous poison is one of the most destructive enemies of our race. Often, this unseen and unfelt tenant of the organism undermines the constitution, and invites the attack of enfeebling or fatal diseases, without exciting a suspicion of its presence. Again, it seems to breed infection throughout the body, and then, on some favorable occasion, rapidly develop into one or other of its hideous forms, either on the surface or among the vitals. In the latter, tubercles may be suddenly deposited in the lungs or heart, or tumors formed in the liver, or it shows its presence by eruptions on the skin, or foul ulcerations on some part of the body. Hence the occasional use of a bottle of this *Sarsaparilla* is advisable, even when no active symptoms of disease appear. Persons afflicted with the following complaints generally find immediate relief, and, at length, cure, by the use of this *SARSAPARILLA: St. Anthony's Fire, Rose or Erysipelas, Tetter, Salt Rheum, Scald Head, Ringworm, Sore Eyes, Sore Ears*, and other eruptions or visible forms of *Scrofulous* disease. Also in the more concealed forms, as *Dyspepsia, Dropsy, Heart Disease, Fits, Epilepsy, Neuralgia,* and the various *Ulcerous* affections of the muscular and nervous systems.

Syphilis or *Venereal* and *Mercurial Diseases* are cured by it, though a long time is required for subduing these obstinate maladies by any medicine. But long continued use of this medicine will cure the complaint. *Leucorrhœa* or *Whites, Uterine Ulcerations,* and *Female Diseases,* are commonly soon relieved and ultimately cured by its purifying and invigorating effect. Minute Directions for each case are found in our Almanac, supplied gratis. *Rheumatism* and *Gout,* when caused by accumulations of extraneous matters in the blood, yield quickly to it, as also *Liver Complaints, Torpidity, Congestion* or *Inflammation* of the *Liver*, and *Jaundice,* when arising, as they often do, from the rankling poisons in the blood. This *SARSAPARILLA* is a great restorer for the strength and vigor of the system. Those who are *Languid* and *Listless, Despondent, Sleepless,* and troubled with *Nervous Apprehensions* or *Fears,* or any of the affections symptomatic of *Weakness,* will find immediate relief and convincing evidence of its restorative power upon trial.

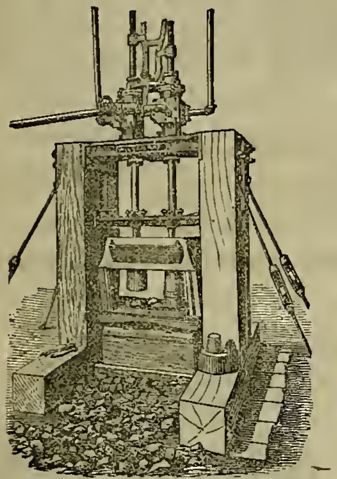
THE WILSON

Patent Steam Stamp Mill.



This extraordinary Mill, now so justly popular in the East, is now offered to the miners of the Pacific Coast. Having been in operation now for about eighteen months, the Company feel confident that the

WILSON STEAM STAMP MILL,

For Durability, Efficiency,

AND ECONOMY OF WORKING,

HAS NO EQUAL.

☞ The Wilson Steam Stamp Mill is the only Steam Mill that has had the severe ordeal of practical working, and proved itself eminently successful. It is now in operation in several of the Eastern States and Territories, and gaining an envious popularity. The whole machine is so simple as to be readily understood by the most ordinary minds. In fact, its simplicity is its durability. Tho expense of crushing rock or cement with this Mill is less than one-half the expense of any other Stamp Mill, and less than one-half the cost. For further particulars inquire of

A. BICKNELE, Agent,
Nevada City, California,

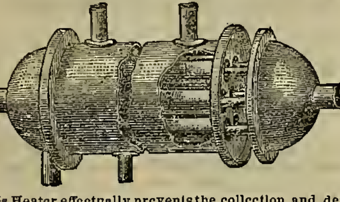
Or of THE WILSON STEAM STAMP MILL CO., 326 Walnut street, Philadelphia, Pa.

Notice.—All persons are hereby warned not to manufacture or use any Steam Stamp Mills that are an infringement on the Wilson Patents, as they will be prosecuted to the utmost rigor of the law.

F. R. WILSON,
20v19-tf Supt. W. P. S. S. M. Co., Philadelphia.

CROSS' COMBINED

Heater & Sediment Collector



This Heater effectually prevents the collection and deposition of sediment in the boiler from impure water. From April 1, 1869, the Royalty on this Heater has been

REDUCED 45 PER CENT.,

Which enables the Vulcan Iron Works, McAfee, Spiers & Co., Risdon Iron Works, of San Francisco, Keep & Bargion of Stockton, and Williams & Co., of Sacramento, the parties having the right to build them, to furnish these Heaters at greatly reduced rates. Send for Circulars to

WM. B. CROSS,

VARNEY'S

PATENT AMALGAMATOR.

These Machines Stand Unrivaled.

For rapidly pulverizing and amalgamating ores, they aave no equal. No effort has been, or will be, spared to have them constructed in the most perfect manner, and of the great number now in operation, not one has ever required repairs. The constant and increasing demand for them is sufficient evidence of their merits.

They are constructed so as to apply steam directly into the pulp, or with steam bottoms, as desired.

This Amalgamator Operates as Follows:

The pan being filled, the motion of the muller forces the pulp to the center, where it is drawn down through the aperture and between the grinding surfaces. Thence it is thrown to the periphery into the quicksilver. The curved plates again draw it to the center, where it passes down, and to tho circumference as before. Thus it is constantly passing in a regular flow betwoen the grinding surfaces and into the quicksilver, until the ore is reduced to an impalpable powder, and the metal amalgamated.

Setlers made on the same principle excel all others.—They bring the pulp so constantly and perfectly in contact with quicksilver, that the particles are rapidly aud completely absorbed.

Mill men are invited to examine these pans and setlers for hemselves, at the office, **229** Fremont street,
1v1 San Francisco.

THE GREAT MEDICAL DISCOVERY!

Dr. J. Walker's California

VINEGAR BITTERS.

FOR FEMALE COMPLAINTS, whether in young or old, married or single, at the dawn of womanhood or the turn of life, these Tonic Bitters display so decided an influence that a marked improvement is

More than 500,000 Persons

Bear testimony to their wonderful Curative Effects.

WHAT ARE THEY!

soon perceptible in the health of the patient. PIN TAPE, and other WORMS, lurking in the system of so many thousands, are effectually destroyed and removed. ☞ Send for a Circular. ☜

They are not a vile

FANCY DRINK,

Made of Poor Rum, Whiskey, Proof Spirits, and Refuse Liquor, doctored, spiced, and sweetened to please tho taste, called "Tonics," "Appetizers," "Restorers," etc., that lead the tippler on to drunkenness and ruin, but are a true Medicine, made from the native roots and herbs of California, free from all alcoholic stimulants. They are the GREAT BLOOD-PURIFIER and LIFE-GIVING PRINCIPLE, a perfect Renovator and Invigorator of the System, carrying off all poisonous matter, and restoring the blood to a healthy condition. No person can take these Bitters according to directions and remain long unwell.

They are a gentle Purgative as well as a Tonic, possessing, also, the peculiar merit of acting as a powerful agent in relieving Congestion or Inflammation of the Liver, and all the Visceral Organs. In Bilious, Remittent and Intermittent Fevers, these Bitters have no equal. For full directions, read carefully the circular around each bottle, printed in four languages—English, German, French and Spanish.

One Hundred Dollars will be given for an incurable case, provided the bones are not destroyed by mineral poisons or other means, and the vital organs wasted beyond the point of repair.

For Inflammatory and Chronic Rheumatism, and Gout, Dyspepsia or Indigestion, Bilious, Remittent and Intermittent Fevers, Diseases of the Blood, Liver, Kidneys and Bladder, these Bitters have been most successful. Such Diseases are caused by Vitiated Blood, which is generally produced by derangement of the Digestive Organs.

Cleanse the Vitiated Blood whenever you find its impurities bursting through the skin in Pimples, Eruptions or Sores; cleanse it when you find it obstructed and sluggish in the veins; cleanse it when it is foul, and your feelings will tell you when. Keep the Blood pure and the health of the system will follow.

WIESTER & CO.,

PATENT BROKERS,

No. 314 Bush Street, San Francisco.

PATENTS BOUGHT AND SOLD ON COMMISSION.

For the benefit of those who live at a distance from the city, we give below a brief description of a few of the valuable Patents which we have in our office. It may be well to state here that no Patent is received by us for negotiation until it is first endorsed by reliable experts, to whom each is subjected for acceptance or rejection. We treat all patents alike, recommending only where true merit is found in the invention.

Odermatt & Ettlin's Fountain Pen.

PAT'D. AP. 6. 1869.

We call the attention of manufacturers to this new invention for supplying writing and drawing pens with a constant flow of ink. The pen-stalk contains sufficient ink to last for two or three days' constant use, and is provided with stop-cocks, which make it perfectly safe for carrying in the pocket. The flow of ink is under perfect control of the operator. A slight pressure on the thumb and fore-finger on the elastic sides of the holder is all that is required to regulate the flow of ink to suit the writer. It never blots unless forced to do so. The cost to manufacture is small, and the demand for a good Fountain Pen is very extensive among all classes of literary and business men. A sample of this invention can be seen and tried at our office, 314 Bush street, San Francisco. The entire Patent, or the Right for any State, can be bought on reasonable terms. Full particulars furnished on application.

NEW LIGHT ON A NEW PRINCIPLE.

Gas for everybody in the city and in the country. Equal to coal gas at one-half the cost. The gas is generated and burned in a new style Vapor Lamp. No wick, no chimney, no explosion; and no man who is out of business and has a few dollars should fail to purchase a County or State Right and commence making money. Parties owning territory get the Lamps at Manufacturers' prices. Call and examine the light, or write for particulars.

A NEW PAPER FILE AND MUSIC FOLIO.

Two excellent inventions included in one patent. Either can be manufactured at a small cost, and neither has an equal in its line. No more expense for binding music. Each sheet has a complete and durable binding as soon as it is placed in the folio. The California Legislature has endorsed the Paper File by purchasing three hundred and fifty, to take the place of the old style binders. It certainly is the most complete article of the kind ever invented. Whoever buys the right to manufacture and sell this invention will secure a good basis for a profitable business. Only the Territory west of the Rocky Mountains for sale. Parties in the city should call and examine the article. Full particulars furnished on application.

Important to Assayers.

Crucibles.

The Patent Plumbago Crucible Co.

Manufacturers of all kinds of
Melting Pots, Portable Furnaces,
CRUCIBLES, and other fire-standing Goods,
Battersea Works, London.

THE MORGAN PATENT CRUCIBLES have uniform quality, never crack, withstand the greatest heat without danger; heats more rapidly than any other; change of temperature has no effect on them; stand on the average forty to fifty pourings.

CERTIFICATES:

United States Branch Mint, San Francisco, Cal., March 12, 1869—Messrs. A. S. Hallidie & Co., Agents Morgan Crucible:—I have carefully tested the Morgan Patent Plumbago Crucibles purchased from you for the U. S. B. Mint, and cheerfully certify to their superiority and economy over all other Crucibles used by and under me. They are fully what you represent them, and I shall continue to use them in preference to any other. J. M. ECKFELDT,
Melter and Refiner, U. S. B. Mint.

Eagle Brass Foundry, 206 Fremont street, San Francisco 12th March, 1869—Messrs. A. S Hallidie & Co., 519 Front street—Gentlemen:—We have used and tested the Morgan Patent Plumbago Crucible, for which you are agents, and pronounce them superior to and cheaper than any Crucible used by us heretofore. GREENBERG & MOORE.

Messrs. A. S. Hallidie & Co.:—We have thoroughly and severely tested in every way the Morgan Patent Plumbago Crucible obtained by us from you, and find them superior to any we have yet tried, although we have used every pot obtainable in this market, we have none equal to the above, and concede your claims for them. We think they will average 45 pourings of brass.
GALLAGHER, WEED & CO.,
California Brass Works, 125 Front street, San Francisco.

Assay Office of H. Harris, Silver City, Nevada, April 24, 1869—Messrs A. S Hallidie & Co.—Gents.:—I received from you three Crucibles of the Morgan make, which I have used since their arrival, and tested by constant use. Since 1847, when in the New Orleans Mint, I have always preferred the Crucible of Dixon's make over Adus, Gautier, and Taunton, Mass. Yours I find to be not alone of more finished make, but to stand double or treble the work of Dixon's Crucibles. The No. 12—the smallest sent—has stood so far 32 meltings, and is as good and sound as when received. Your Crucibles do not scale off like others; and as they are forty per cent. cheaper, I do not see why they should not be preferred by all assayers on account of durability and cheapness. Yours respectfully, H. HARRIS.

On hand and for sale by the Agents,
A. S. HALLIDIE & CO.,
18v18-9p 519 Front street, San Francisco

Sheffield Scientific School

Of Yale College, New Haven, Conn.

This department of Yale College, instituted in 1840, and endowed with the National Land Grant in 1866, furnishes advanced instruction in the various branches of Mathematical, Physical, and Natural Science.

The School is under the direction of the President of the College, a Board of thirteen Professors in different specialties, and six assistant instructors.

Regular courses of study, leading to the degree of Bachelor of Philosophy, conferred by Yale College, are arranged as follows: 1—Chemistry and Mineralogy. 2—Civil Engineering. 3—Mechanical Engineering. 4—Mining Engineering and Metallurgy. 5—Agriculture. 6—Natural History and Geology. and 7—Select Course.

Advanced students are also admitted to optional courses, and if already College graduates, are received as candidates for the degree of Doctor of Philosophy.

Tuition, $125 per year of forty weeks.

The Libraries, Museums, Laboratories and Apparatus accessible to students, are varied and extensive.

For copies of the Annual Circular and Report, letters may be addressed to the "Secretary of the Sheffield Scientific School," New Haven, Conn. v16-1y16p

Patent Solicitors.

San Francisco, Saturday, April 30, 1870.

VOLUME XX.
Number 18.

Swamp Lands near San Francisco.

E. L. Beard, Esq., is engaged in a very extensive reclamation of the salt marshes on the eastern shore of the bay of San Francisco, beginning at Alviso, the head of the bay, and extending beyond the Mission of San José. The area comprises 21,000 acres, which Mr. Beard has bought from the State. In its present state, the land has no value, being overflowed at high tide with salt water. But when the salt water is shut out by embankment, the soil has no superior. Besides the overflow from the bay, these marshes have winter overflow from the Alameda and other fresh water streams, which spread their floods over all the land. This makes it necessary to cut channels of sufficient capacity to confine the streams to fixed boundaries.

To protect against salt water, embankments are being made by Chinese labor, by which this kind of work is admirably executed. There being very little pressure from the bay waters, a very slight dyke is required compared with Sherman Island; but the proprietor gives his embankments much broader bases than the island reclaimery. The bay walls are mostly twelve feet base, two and a half feet high, and eight feet top level. Here and there they are sixteen and eighteen feet base, and four to five feet high. They cost from ninety cents to two dollars a rod. The sloughs are extra work of greater cost. The sod is not turfy. It cuts like a bank of wet clay; and the square clods are built up into the embankments after the fashion of solid masonry. Sufficient of this marsh land has been reclaimed, from time to time, to prove that the salt soon works out and all crops grow well on it.

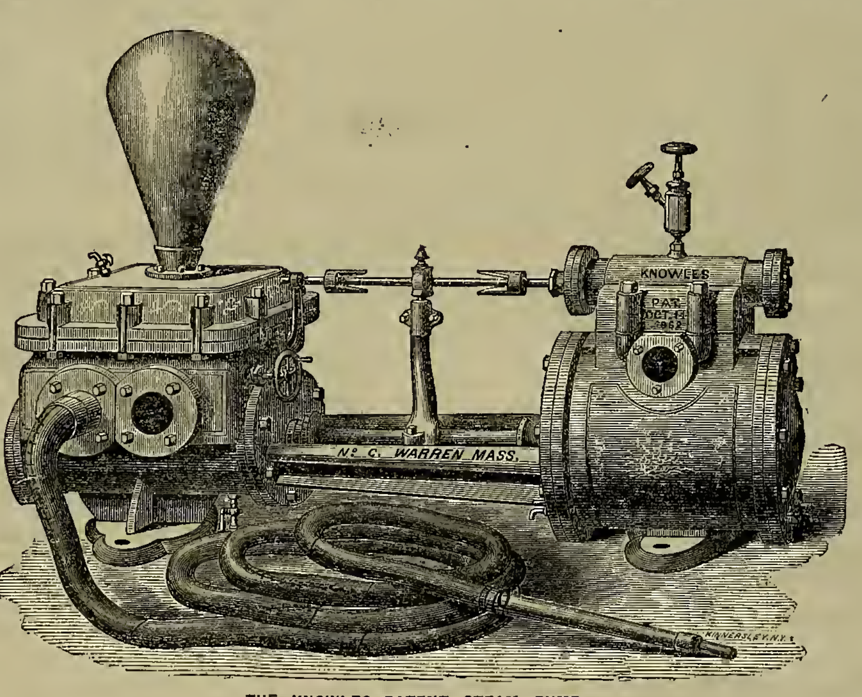
But it has peculiar advantages that fit it for rice culture. It has complete command of fresh water, and can be overflowed at pleasure. For wheat, we do not want accession of land under present prospects; but we do want rice land; and we trust that this large area will be appropriated to its cultivation. In a very short time we can be independent of imports, and we can find outside markets for rice in favorable competition with Asiatic countries. Let no one doubt the adaptation of our climate to this useful grain. Rice men from China and Japan have pronounced it fully equal to their own; and they say that rice never fails of a crop on lands of such moist subsoil, when irrigation is also at command.

◆

Blossom Rock.—The explosion last week was a perfect success. The central column of water was thrown up to a height of 225 feet, and the rest followed in a huge mass to a height of 80 feet. Surveys since made demonstrate that the rock was demolished so that at low tide there are now 38 feet of water over it. The thanks of the community are due to Col. Von Schmidt, as well as to his brother, who has had the actual operations in charge, and who deserves prominent mention in this connection; and all will agree that the price of the contract has been deservedly won.

The Knowles Patent Steam Pump.

The annexed cut represents the Knowles Direct Acting Steam Pump, which was patented by Mr. L. J. Knowles in 1859, and which has since met with a most favorable reception by engineers and mechanics, a guarantee that the high claims made by its manufacturers have a good strong foundation. Among the advantages thus claimed for this pump we may mention several for the benefit of that class of our readers who are interested in this subject, and who desire to know the principal points of the many steam pumps offered to the public.



THE KNOWLES PATENT STEAM PUMP.

It has no cranks or fly-wheels, no dead points (it is asserted), and is always ready to start when steam is admitted, without the need of lever or starting-bar to start it, or handiwork to get it past the centers. It will work its steam valve with water, and consequently is in condition to start up although the cylinder and steam chest are filled with the water of condensation. The arrangement of the steam valve with the ports is such that whenever the throttle-valve is opened the steam has a free passage into the cylinder, or should the valve (an ordinary D or slide-valve) be in position to cover the ports, the piston valve takes steam and carries the slide valve past these, therefore allowing the great desideratum of a minimum speed. This pump controls its valve by steam when working very slowly or at a moderate speed, but when working at its greatest capacity the tappet connection to the piston rod drives the valve before the steam in the chest has time to throw it, showing that the momentum of the piston carries the valve reversing the stroke more quickly than can be done in a pump depending on steam alone to work its main valve. Here is the advantage claimed over all other pumps:—Having two connections with the main valve (by steam and tappet arm), thus making it impossible for the piston to strike the heads, for the valve being driven ahead of the piston, the steam must necessarily stop and immediately reverse it. The parts, which are comparatively few in number, are made so that any one can be replaced, if broken, by the extra piece which is always to be obtained from the agents. There is no gum packing, the joints being all ground, and the whole is built exceedingly strong and durable.

So much for the advantages claimed. With regard to the opinion of engineers and others, we find that this pump has received the highest premiums in Boston, New York (1863), Baltimore. Cincinnati, Buffalo, Syracuse, Springfield and Worcester, and the first medal and diploma over all competitors at the Fair of the American Institute held in New York in October, 1869.

The largest of the kind ever built are used at the Fairmount Water Works, supplying the city of Philadelphia. At the Hoosac Tunnel are several of the same build, one weighing 217 pounds over 10 tons. They are to be found in the coal and iron mines in Pennsylvania, the silver mines of Mexico, the copper and silver mines of South America, and are patronized by the Novelty, Delameter and other large works in New York and elsewhere. The N. Y. Central, and the Erie, Harlem, N. J. Central, Union and Central Pacific and other railroads have them, and they have the recommendation of the Chief Engineer of the Navy for use in the navy yard and government steamer, of the New York and Boston Board of Fire Insurance Companies and of many others.

This device is adapted for any purpose when pumping is required, and may be obtained of Messrs. Steen & Cushing, general agents for the Pacific coast, No. 9 First street, San Francisco.

◆

Ready-made Houses.

The *Manufacturer and Builder* tells us that houses are kept on hand in Chicago for sale. The parts of the house can be packed in a small space, as furniture is now packed in pieces, ready to be put together at the place desired. As an instance, it says that a house was ordered in the evening to be erected next day twelve miles off. In twelve working hours the house was ready for occupancy. Houses ordered for the sea-side in Connecticut have been sent there and occupied in ten days from the date of the receipt of the order in Chicago.

Just now the manufacturer is sending to new towns on the Pacific Railroad seven ready-made churches for the Presbyterians, intended for immediate occupation.

All that the journal seems to know about the method of construction is, that all the parts are packed in dozens—viz: twelve sashes, twelve doors, twelve frames, etc. Large orders are being supplied by railway to places west of Omaha. We find no mention of the cost, but we infer that it is low.

Would it not be well for some of our San Francisco mechanics to get up houses on this plan for transportation to such interior localities as have to draw their lumber supplies from this city? It will cost no more to deliver houses so made up than the lumber in the rough for their construction, at the point desired. Moreover, the facilities for the use of machinery in San Francisco gives great advantage in getting out many of the parts which must be prepared by hand labor in the country. Our climate is well adapted to light structures; and if Chicago can send them to the Atlantic shores, surely our mechanics ought to be able to send them over the shorter distances required on this coast.

◆

The San Francisco Microscopical Society, lately organized under favorable auspices, held its regular meeting Monday evening. A congratulatory letter was read from the American Microscopical Society of New York, which society sent, with the letter, some very interesting specimens of diatoms. A number of persons were elected resident and corresponding members, and the Corresponding Secretary was instructed to open a correspondence with the various microscopical societies of the world. We wish the Society all success, which, from a personal acquaintance with some of its members, we doubt not it will obtain.

Ore Deposits.

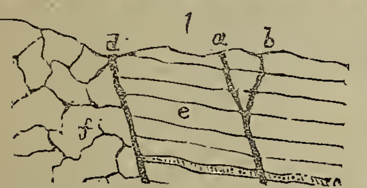
[Prepared from various German works for the Scientific Press, by Guido Küstel.]

In what Condition the Metals are found in Nature.

The metals occur either in metallic condition, as gold, silver, platinum, lead, copper, mercury, bismuth; or they appear as alloys; for instance, silver amalgam, platiniridium; or, most frequently, in an orey state, or mineralized—that is, chemically combined with other substances—whereby the appearance of the metal and its nature are entirely changed; thus we find silver, copper or lead combined with sulphur, as silver or copper glance and galena. The substances with which the metals are found in combination are principally: sulphur, arsenic, chlorine, carbonic acid, oxygen, and some less frequent bodies, as selenium, tellurium, etc.

How the Ore is Deposited in the Earth.

The ore is found in *fissure-veins, layers, stockwerks and impregnations.* Veins are often filled with minerals differing from those constituting the surrounding country rock in which they are imbedded. The rock overlaying a vein is the top or hanging wall, in opposition to the foot-wall or underlayer on which the vein lies. Noting the course or direction and the dip or inclination of a vein by means of compass and level, its situation can be described minutely. The width of a vein is measured by the rectangular distance from the hanging to the foot-wall.



What a Fissure-Vein Is.

A fissure-vein may be designated as a fissure, resulting from plutonic or volcanic actions, or shrinkages of the earth's crust, extending to an immense depth, wherefrom the vein matter originates. The most of the ledges having a considerable width and depth are fissure-veins, but also smaller ones belong to the same class.

Fissure-veins do not run parallel with the stratification of the country rock. They are always younger than the country rock in which they are imbedded. In Fig. 1, *a* represents a fissure-vein in gneiss, with a spur-vein, *b*.

The term "true fissure-vein" seems to be used for a fissure-vein of an endless depth. This term is not very proper, since all fissure-veins are "true." If it is no true fissure-vein, it is no fissure-vein at all.

Mother-Veins.

The term mother-vein is applied generally to a vein of the largest dimensions, in course and width, amongst other smaller veins in its proximity, but it is wrong to combine therewith the idea of the mother-vein being the oldest, and hence the source of the smaller ones. The largest veins amongst others of different age is sometimes the youngest one.

How Wide the Fissure-Veins Are.

The width of different mineral veins varies to a great extent, from less than one-half an inch to several hundred feet, but the majority of veins will be found from one to four feet wide. The width is not permanent, but changes often; it has been observed, however, that the wider a vein is the more regular it runs. It may be mentioned here, that there are veins entirely bare of metals, consisting of granite, basalt, greenstone, etc.

To what Depth the Fissure-Veins Continue.

The depth of wide fissure-veins is unknown as yet; almost all of them continue towards the internal hot region, whereto they never can be followed. But although untraceable, it is not said that a fissure-vein continues as far as the fluid masses beneath the earth's crust. Smaller fissure-veins discontinue sometimes at different depths. These veins were filled from above by infiltration.

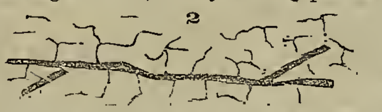
Only few mines are opened beyond a perpendicular depth of 2,000 feet. In regard to the ore, although many veins appear to be richer on the top, it is by no means a consequence that all veins are getting poorer by increasing depth, or that metals cease at a certain depth. They are often found to appear in strata alternating with dead masses, the latter filling up the veins sometimes to a considerable depth. It is on account of these barren masses in deeper regions that mines are often abandoned.

What a Contact-Vein Is.

A contact-vein is imbedded between two different kinds of rock. For instance, if one wall is granite, the other limestone, the vein between is a contact-vein, forming the boundary between those two rocks. Between the granite, *f*, of Fig. 1, and the gneiss, *e*, is the contact-vein, *d; c* shows a layer-vein.

How the Fissure-Veins Generally Appear.

Generally, fissure-veins are found socially. When one vein is discovered, it is very probable that more may be found in the neighborhood, mostly running parallel and generally of the same character. Parallel veins appear often in groups. Frequently they are found in confusion running in every direction, often crossing each other several times and forming a sort of network.



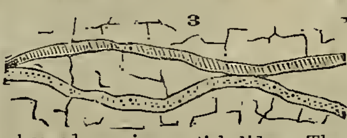
If two veins cross each other, the younger passes through the older, as, for instance, the vein, *a*, in Fig. 1, cutting the older vein, *c;* but there are also cross-veins which were filled at the same time, consequently no real crossing of the vein matter can be discovered. Some veins join each other at a certain point, but instead of crossing run, running together, the older keeping its course. Sometimes they part again or cross each other, as shown in Fig. 2. It occurs also that two veins will meet under a sharp angle, part again, or remain together for a short distance, as seen in Fig. 3, or in Fig. 4, where the vein, *a*, crosses *b*, sometimes repeatedly, and is found alternatively on the hanging and on the foot-wall of *b*.

Are Veins Found to be Cut Off?

Veins appear sometimes suddenly to give out. It is, however, mostly the case, that, being traversed by another vein or fissure, it is dislocated, not continuing, therefore, in its original course on the other side of the crossing, but found at a certain distance in some direction, depending on the slide which took place horizontally, vertically, or between both of them. The fault occurs either through the motion of the hanging or of the foot-wall, or sometimes through the motion of both in different directions.

The Cause of Dislocations.

The faults and dislocations of veins are due to some mechanical subterranean force of volcanic nature, whereby the rocks are upheaved, causing partial slides. The displacement of a vein depends on the extent of the slit and on the angle caused by the direction of the shift with the cross line of both veins; but it is very difficult for the miner to make any reliable suggestion as to the point where the displaced vein may be found, unless guided by experience in the same vein. For instance, a vein is displaced by a younger fissure, and the distance and direction of the displaced vein found; it is then easily calculated where the exact place of a second vein is to be found, if displaced by the same first younger fissure. The faults are often exceedingly complicated if several veins are dislodged by successive younger ones. By the powerful friction of sliding veins, often beautifully polished surfaces are produced as if glazed, sometimes scored with parallel furrows and ridges, by which the direction of the slip is indicated. The hanging-wall is generally the sliding part. A complicated disturbance by faults can be seen in Fig. 5, representing a mine in Cornwall. Here, *a* is the oldest vein, carrying tin ores, and is dislodged by the two copper veins, *b* and *d; e* is the youngest vein, filled with clay, disturbing the copper vein, *b*, and also the tin vein, *a*.



Distribution of Ores in Fissure-Veins.

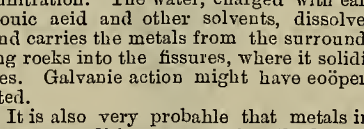
In most of the fissure-veins there is no regularity. Nearly all show richer and poorer regions, local deposits or bonanzas, nests and pockets of ore. Sometimes the ore accumulation sets down in a certain direction called a chimney. The causes of the unequal distribution of ores is not known as yet. It is often observed, that gold especially is found richly impregnated in the quartz of outcrops or near it, but poor when followed downwards. High elevated veins are generally richer than those found in valleys or flat lands. The width of a vein seems to have an influence on the distribution of ore, as it is no rare occurrence that veins become richer when narrower; but this is not always the case. A vein appears richer if joined by one or two others, or if crossed.

Influence of the Country-Rock on the Character of the Ore.

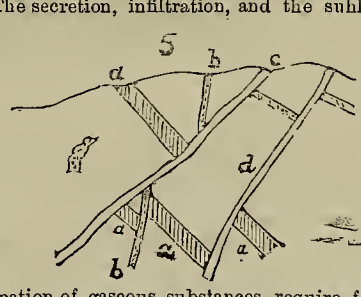
The observation has been made frequently that fissure-veins passing from one formation into another, change in richness. There are veins which, entering another rock strata, loose the ore entirely, but gain it again in crossing rock of the first character. At Kongsberg, Norway, the veins are richer in gold when passing through mica slate and gneiss. The tin veins at Altenberg, Saxony, are rich when in porphyry, but poor in granite and syenite; as soon, however, as they enter porphyry again, they become rich as before. These are local occurrences. A country-rock favorable for the ore in one locality, may prove the reverse in another region. The gold and copper veins in Carolina become locally richer whenever they meet or cross another sort of rock. Similar circumstances are very numerous.

How the Fisseres were Filled with Ore.

The theory of fiery liquid masses, which were supposed to have entered the fissures upwards from the interior of the earth, has not many advocates now. It can not explain how the silicate of iron of a molten mass containing other metal oxides besides, could be disengaged and transformed into pure white quartz, impregnated or in company with different crystallized sulphurets, native metals, etc. Also, the texture in many veins of a symmetrically stratified condition, speaks against the above hypothesis. Besides, it hardly could be supposed that a fissure could reach the very fluid mass of the earth's interior. More in accordance with the observations, is the theory that veins were filled with ore by infiltration. The water, charged with carbonic acid and other solvents, dissolves and carries the metals from the surrounding rocks into the fissures, where it solidifies. Galvanic action might have coöperated.

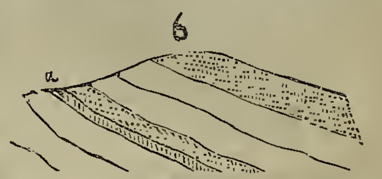


It is also very probable that metals in gaseous condition penetrate into the fissures repeatedly, at different times, and being condensed or precipitated, fill, by degrees, the space. This process, under certain circumstances, might be interrupted and finished by infiltration. According to Prof. Cotta's opinion, it is impossible to establish a theory explaining the filling of veins generally, but different veins, having been formed in various ways, must also be explained accordingly. Many metalliferous veins, especially such as expose symmetrical layers containing quartz, carbonates of lime and magnesia, fluorspar, heavy spar and sulphurets, were undoubtedly formed by precipitation of liquid solutions. The texture and nature of the composing minerals show this distinctly. The solution may originate from an immense depth. The secretion, infiltration, and the sublimation of gaseous substances, require, for completion, an incalculably long period, in which the different minerals are formed in succession, and this explains the corresponding stratas of different minerals in a vein which never could be considered as the result of an injection of a hot fluid mass, which would fill up the fissure in a short time with a uniform compound; but it is not absolutely impossible that a certain class of ores in a hot liquid condition, produced by the melting of already existing deposits, may fill up veins and refrigerate therein.



Did the Ore Remain Unaltered from the Beginning?

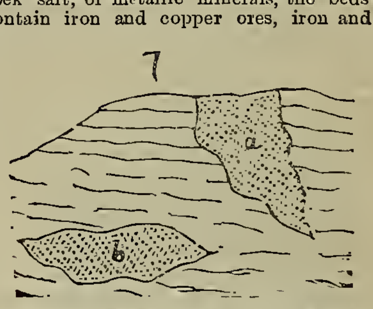
In very many veins the ore was exposed to numerous changes after the first formation, partly by changing their elements and partly by intrusion of substances from above; as water, oxygen, phosphorus, carbonic acid, etc. For this reason, in lead veins we find carbonate, sulphate, phosphate and arsenate of lead; in copper veins, malachite and lazurite, phosphate of copper, etc. Where volcanic rock abounds, as in Arizona, Nevada, etc., the ore often appears metamorphosed. On and near the outcrops, where the ore is in contact with air and moisture, carbonates are predominant; deeper down they appear as oxides, with a trace of sulphur or without, showing a horny appearance as if acted upon by heat. A very frequent ore of this kind is the Stetefeldite (in Nevada and Arizona). Copper oxide, lead oxide, a mineral of light and dark color, antimony oxide of a light yellow color. The last three minerals, are found in Arizona, and show a similar horny appearance as the Stefeldite.



A Layer or Bed.

Beds or layers differ from fissure-veins principally by being deposited between stratified rocks, lying parallel with the strata of the rock. Contact-layers are imbedded between two different kinds of stratified rocks. The origin of beds appears identical with that of the surrounding rocks. A symmetrical stratification of different minerals, such as is sometimes found in fissure-veins, is never found in beds. Their original position is generally but little inclined, but they occur also steep. Compared with fissure-veins, the layers are often found wider, but less extensive in length and depth. They are exposed to faults and dislocations like fissure-veins, although less frequently.

Some minerals found in beds never occur in fissure-veins, as coal, lignite and rock salt; of metallic minerals, the beds contain iron and copper ores, iron and copper pyrites, lead ores, blende, galmei, etc. Fig. 6 shows a nearly horizontal layer-vein.



Stockwerks.

Spheroidic, elliptic or otherwise irregular accumulated masses of ore, distinctly separated from inclosing rocks, are called a "stock" or stockwerk, the latter applicable where a system of such deposits is found. A stock differs from a bed or layer by its very irregular shape, showing generally a great width, extending horizontally or vertically, and occurs generally on the border of different rocks or near to it, especially in crystalline slate-formation with limestone, or with crossing eruptive rocks, in limestone or dolomite. A stock ends very often in the shape of a wedge each way.

Iron ore mostly is found in stocks, but also lead, copper, silver and gold ores. In Fig. 7 a vertical stock is represented by *a*, and a horizontal one by *b*.

Impregnations.

The ore appears sometimes in such a singular condition that its classification amongst veins, beds or stocks, as it was done heretofore, seems to be quite improper. Professor Cotta proposed to adapt the term "impregnation" for ore-bearing rocks having an uncertain external boundary. The rock appears spotted or impregnated with particles of ores, extending in different directions without showing a distinct line of its ending. It is very probable that the ore penetrated certain regions of a rock subsequently, but there might be found also similar beds in which the ore was distributed originally in that way. The impregnations occur independent for themselves, but often also combined with other lodes in the hanging and foot-wall.

The independent impregnations form extensive bed-like regions in country rock. They are sometimes so minute as to be invisible to the naked eye, but in other cases again they appear in small crystals or grains, equally distributed or partially concentrated. Tin and quicksilver are often found as impregnations, but also gold, silver, copper, lead, zinc, cobalt, nickel, bismuth, arsenic, iron and manganese-ore.

Mechanical Progress.

Variable Expansion Gear for Winding Engines.

M. Audemar, engineer of the mines at Blanzy, France, is the inventor of a new apparatus of this kind, which is said to secure a very important saving in boiler space and in fuel. *La Houille* thus describes it: "The apparatus consists of a double cam, one-half of which serves for the forward stroke, and the other half for the back stroke. Each portion of this cam has varied profiles, so as to give the various degrees of expansion, from the smallest to the greatest; and it is so disposed that the middle becomes the neutral point, like that of the Stephenson slide, and corresponds, like it, to no admission, whilst the two extreme points give full open. A valve on the Cornish system, placed before the ordinary distribution of the machine is used to produce the expansion of the steam. This valve is put in motion by the cam, the rotation of which is caused by the gearing on the shaft of the engine, and it opens and closes according as one or other part of the cam is for the time being in operation. If the Stephenson slide be at its neutral point, the cam would be in a similar position, and the two being set in motion by the same lever, will at the same time occupy the extremes of their course. If, then, the engineer inclines his reversing lever, the several profiles of the cam being presented to the valve, produce a corresponding cut-off, which will become absolutely none if the lever be pushed full home. Thus, the mere inclination of the lever which the engineer already uses, suffices to produce the desired effect both for the forward and backward movement."

A Novelty in Steam Engines.—An engine has recently been patented which has two cylinders;—one, the primary cylinder, which is within the boiler, and the other, the atmospheric cylinder, which is exterior to it. The two pistons are upon opposite ends of the same rod. The pressure of the steam upon the water in the boiler forces it into the open end of the inner cylinder, driving its piston outwards. The steam above this piston exhausts into the outer cylinder, and, by expansion, counterbalances the pressure of the external atmosphere against its piston, its outer end being open; the stroke in this direction being completed, the valve cuts off the exhaust, and admits the steam again into the inner cylinder above the piston, which in its turn counterbalances the pressure of the water against the opposite side of its piston,—the outer cylinder at the same time exhausting into the outer air.

Steel-making in Pennsylvania.—A number of gentlemen in Allentown, Pa., have formed an association for the manufacture of steel and iron by the "Excelsior Process," and have already commenced operations. The *Daily News*, published at that place, says that a large number of chisels and other tools have been made, in which any desired temper can be secured; and some of the most experienced mechanics have used and worked this steel, and declare it to be equal to the best cast steel for strength and retension of fine sharp edge under hard use. At the Rolling Mill they rolled several steel top rails with such perfect success that when the first rail was run out the puddlers and rollers cheered. The lower part of the rail was made of wrought iron and welded so perfectly that by placing a short piece of the rail under the powerful crusher at the mill it broke lengthwise in the iron below the weld. The manufacture of steel under this process, it is claimed, costs but a trifle more than wrought iron.

Large Photographic Lens.—The largest portrait lens ever made in England was recently completed. It is 10½ inches in diameter. It admits so large a volume of light that photographs covering a space of 10 by 12 inches may be done in eight seconds. In the open air, groups of 15 to 20 persons (each face about the size of a sovereign, and the whole picture 24 inches by 24 inches) can be taken with an exposure of 10 seconds. The cost was upwards of £200.

Toning of Photographs.

The following is an extract from an article on "Practical Photography" in *The Engineer:* A good standard toning bath may be made of chloride of gold one grain, pure acetate of soda thirty grains, water eight fluid ounces; it should be mixed a day or two before required, and may be used over and over again for some time, a little fresh chloride of gold being added now and then as the solution weakens. Another very good toning solution may be made by shaking up some solution of chloride of gold, strength one grain to the ounce of water, with a few grains of chalk to remove the free acid. Then take of this solution ten drachms, acetate of lime twenty grains, chloride of lime one grain, hot distilled or rain water twenty ounces. This mixture improves by keeping, and to use it add two ounces of it to eight ounces of tepid water, and use the liquid thus produced to tone the pictures. This toning solution tends to give good black tones, and the first one here given produces rich violet tones. Another toning solution may be mixed thus:—Solution of bicarbonate of soda (strength, eight grains to the ounce of distilled water) forty minims; solution of chloride of gold (strength, fifteen grains to five drachms of distilled water) twenty minims; distilled water four ounces; mix these an hour before use.

A Valuable Iron Bed.—A large deposit of iron ore has been recently opened up in York county, Pa., which is said to have the remarkable quality of turning pig iron into good merchantable steel, by simple mixture and manipulation with the pig iron in a puddling furnace of the ordinary construction. It has been tested by several experienced iron makers, and the facts vouched for. The Philadelphia *Ledger* says: "The chemical analysis of the ore shows the presence of considerable quantities of manganese, silicon, and aluminum with the iron. The ore is soft and friable in the bed, so much so that it can be mined with the spade, but upon exposure to the atmosphere it soon hardens. Professor Lesley, who has examined the ore bed, estimates the contents at 17,000,000 tons. For a few months past the discovery has made quite a stir among the iron furnaces and rolling mills of our State and Maryland, and there is a strong desire to know more of a matter that seems to promise such important results."

De-railment of Trains.—A correspondent of *Engineering* says that the chief cause of the violent oscillation of a train which so greatly increases the danger of being thrown from the track when at great speed, is the side throw of the engine from left to right and *vice versa*. He says: "The cause of such oscillation is that all engines have right and left-hand cylinders; thus assuming that the steam is admitted at the back or plain side of the right-hand piston, and, at the same time, at the front or rod side of the left-hand piston, it is very evident that the front end of the engine will be thrown violently against the right-hand rail; and, although the weight of the engine and cone of the wheel may, in some measure, counteract this indirect thrust, still it cannot altogether obviate this strong blow against the flange of the wheel; and, as this is in full operation during the full journey of the engine, the wear and tear of the stock and roads are necessarily very great, as well as the great risk of 'de-railment.'"

The New Engine at Brooklyn.—The splendid engine recently completed for the Brooklyn Water Works has a steam cylinder 85 inches in diameter with 10 feet stroke, and delivers through a 36-inch force-tube a constant stream of water into the reservoir, a distance of 3,450 feet and a height of 166 feet. The flow of water into the reservoir is perfectly even. The actual work accomplished, as appears by the reported experiments, is as follows: For every hundred pounds of coal used, 72,000,000 foot pounds have been produced; that is, 72,000,000 pounds of water were raised one foot high, which is equal to 426,000 pounds, or about 50,000 gallons, raised 170 feet into the reservoir; so that for every pound of coal consumed under the boilers, the engine throws 500 gallons of water into the reservoir.

Scientific Progress.

Muscular Oxidation Independent of Organization.

Becquerel looks upon the organism as a mechanism, and upon muscular respiration and nutrition as accompanied by *electro-capillary* currents, the intensity of which is proportioned to the energy of the chemical action which is going on. He details before the French Academy some experiments to determine whether the oxidation which occurs in muscle after death is similar to that which goes on in living bodies by means of arterial blood. He placed a bit of muscle from a recently killed ox in a glass filled with oxygen. In another glass, similarly filled, he placed a piece of the same muscle reduced to pulp. Two similar preparations were made and placed in hydrogen gas. In the oxygen, with the muscle intact, the effect was the same as in the presence of arterial blood; there occurred a consumption of oxygen and a formation of an equal quantity of carbon—i. e.. dioxide; in the muscle reduced to pulp, it was the same, only the transformation was more rapid. In the hydrogen there occurred also respiration and formation of carbonic dioxide, which was six times less than in the oxygen. The result in nitrogen was essentially the same. He says, therefore: "One is forced to believe from this, that when arterial blood does not furnish enough oxygen to the muscles to effect respiration normally, the muscles procure it by consuming themselves."

Effect of Temperature on Coal Gas. Experiments were recently made upon this point in the laboratory at the University of Munich. Of these experiments, *Engineering* says: "The illuminating power of the gas at the normal temperature of 64½° Fah. was taken as the standard, and the object was to compare, by means of a Bunsen's photometer, this power with that obtainable when the gas was burnt in the same burner at a higher or lower temperature. The burner was attached to a U-tube. The illuminating power at the normal temperature being represented by 100, it was found that when the U-tube was immersed in snow, so as to bring the temperature of the gas down to 32°, the power was reduced to from 76 to 85; while when a mixture of salt and snow was used to give a temperature of—4°, the power was reduced to from 33 to 40. Heating the gas above its normal temperature was found to have less influence upon its illuminating power than cooling it below that temperature. By immersing the U-tube in boiling water, and thus raising the temperature to 212°, it was found that the power was increased to 104; while when melted paraffine was substituted for the water, and the temperature thus increased to 288°, the power became 118. Thus while a reduction of temperature of about 32° lessened the power by about 20 per cent.; an increase of temperature of 224° raised that power by about 18 per cent. only."

Dr. Livingstone.—The Bombay *Gazette* says the latest date from Dr. L. is July 9th last, near Lake Bengiveolo, into which flows the Chambeze. He reiterates his belief that he has found the sources of the Nile between 10 and 12 degrees south—that is to say, nearly in the position which Ptolemy assigned to them. The waters of the Chambeze and of the Lufira, each connecting together in its course a number of lakes, are believed to enter Lake Tanganyika, and thence Lake Choambe,—which last Dr. L. considers the same as Baker's Albert Nyanza.

Bathybius;—Another Opinion.—In our issue of March 12th we gave Prof. Williamson's idea of the nature of this substance. The opinion of Dr. Wallich does not coincide with this. According to him, Bathybius, instead of being a widely extended *living* protoplasm which grows at the expense of inorganic elements, is rather to be regarded as a complex mass of slime with many foreign bodies and the *debris* of living organisms which have passed away. Numerous living forms are, however, still found on it.

Catastrophism, Uniformitarianism and Evolutionism.

These are "three great schools of geological thought, each of which is more or less antagonistic to the other two. The first accounts for all geological phenomena by the operation of forces different in their nature, or immeasurably different in power,' from those which we now see in action. Among the most eminent of its exponents in modern times may be reckoned Baron Humboldt, M. Elie de Beaumont, Professor Sedgwick, and Sir Roderick Murchison. * * The second, or the uniformitarian, is the doctrine of Hutton and Lyell, by which all phenomena in the past history of the earth are ascribed to forces identical in nature with, and not more energetic than, those now active on the face of the earth. * * The third, or evolutionism, theorizes upon 'the development of the universe from diffused atoms of matter endowed with simple attractive and repulsive forces.' This will be, according to Prof. Huxley, the doctrine of a future era in geological inquiry; catastrophism being the doctrine of the past, and uniformitarianism that of the present. The evolutionists of the present day are few in number but eminent in reputation. Dr. Tyndall, Mr. Herbert Spencer, Professor Huxley, and Sir William Thompson may be quoted as the most prominent leaders in England. The doctrine of the origin of species is indeed merely evolutionism applied to biology, and so far Mr. Charles Darwin may also be considered to belong to this school. Its founder was the great Emanuel Kant."

In Professor Huxley's address to the Geological Society of London, he says: "To my mind there appears to be no sort of necessary theoretical antagonism between Catastrophism and Uniformitarianism. * * Still less is there any necessary antagonism between either of these doctrines and that of Evolution, which embraces all that is sound both in Catastrophism and Uniformitarianism, while it rejects the arbitrary assumptions of the one and the as arbitrary limitations of the other. Nor is the value of the doctrine of evolution to the philosophic thinker diminished by the fact that it applies the same method to the living and the not-living world, and embraces in one stupendous analogy the growth of the solar system from molecular chaos, the shaping of the earth from the nebulous cubhood of its youth, through innumerable changes and immeasurable ages, to its present form, and the development of a living being from the shapeless mass of protoplasm we term a germ."

Dimorphism in Worms.—M. Claparède, the Swiss naturalist, in a recent article on the Annelids, expresses the opinion that the Nereids are transformed into Heteronereids at the time of sexual maturity. He thus concludes: "The fact of animals presenting two sexual forms is not entirely new. The beautiful observation of MM. Leuckart and Mecznikow, and those of M. Schneider on the *Ascaris nigrovenosa*, have made us acquainted with analogous cases among the Nematodes, where one of the generations is hermaphrodite, and the other presents separate sexes. Among the Acalephs, certain Geryonidæ, according to M. Haeckel, and among the Nematodes, the *Leptodera appendiculata*, according to M. Claus, present two sexual forms."

The *American Naturalist* says:—"The bearing of these remarkable discoveries, as well as those of the dimorphic forms of insects, on Darwinism, and especially Professor Cope's theory of the origin of genera, is startling, and strongly confirmatory of the latter phase of the theory of evolution."

Paper Parchment.—We quote the following from a late lecture at the Royal Institution by Dr. Odling: "When sulphuric acid is diluted with half its volume of water, and blotting-paper is immersed for a quarter of a minute in the mixture, and is then well washed in plenty of water, the blotting-paper is transformed into paper parchment; it then has great tenacity, will not permit the passage of water, and will lift heavy weights. Sized paper requires a longer immersion in the acid to become thus parchmentized A slip of paper which, when made into a loop, will just lift a weight of 14 ℔. without breaking, will, after being treated as above with weak sulphuric acid, lift a weight of 75 ℔. without breaking. Mr. Graham, the late Master of the Mint, used parchment paper in his experiments on dialysis, for it has the curious property of permitting none but solutions of crystalline substances to pass through it."

Mining Summary.

The following information is gleaned mostly from journals published in the interior, in close proximity to the mines mentioned.

California.

ALPINE COUNTY.

Items.—*Miner*, April 16th: More Exchequer ore will be sent to Reno for reduction. It will be more closely assorted than before....Prospects in the Globe are more encouraging....Leviathan matters are assuming ship-shape under the new English owner. More hands are put on and a regular increase of force ordered until full. ....We have seen some splendid ore taken out by Geo. Wiseman from the Gould & Curry, up Scandinavian Cañon. The vein is small, but very rich....Schenectady shipped yesterday to San Francisco three tons washed Tarshish sulphurets, worth about one dollar per pound.

Mountain.—*Chronicle*, 16th: On Wednesday and Thursday the Mountain No. 1 claim was surveyed by Surveyor-General Marlette, of Nevada. In the upper tunnel the ledge has a pitch of 27 degrees east. This upsets the theory that the tunnel had passed the ledge. The report of Mr. M. will be received on Monday.

AMADOR COUNTY.

Coney.—*Dispatch*, 23d: This mine which has been lying idle for several months, was sold last Wednesday to a San Francisco company for $22,000. It is supposed that the new proprietors will start the mill up again shortly.

Still Burning.—The fire in the Amador mine was burning at last accounts, and the Eureka shaft is beginning to cave in.

Aqueduct.—Cor. of *Ledger*, April 23d: The Bower Bros. picked up two nuggets of gold, weighing together one-half pound, besides a liberal sprinkling of fine gold. Kent, McKenzie, & Co. have struck diggings in Hawkeye gulch and erected a splendid new hydraulic. James Evans has also put up a new hydraulic at the head of Pleasant valley.

CALAVERAS COUNTY

Railroad Flat.—*Chronicle*, 23d: With the opening of spring, operations in quartz have been resumed. A number of new lodes have been discovered. Cudell, Sanderson & Co., Chapman & Co., Lefoy & Co., and others, have large quantities of ore ready to be crushed as soon as the ground settles sufficiently to permit its being hauled. The Petticoat never looked more favorably. At a depth of 200 feet a lead of high grade ore, from six to ten feet in width, has been developed. A large force of hands is constantly employed. We are credibly informed that several custom mills will be erected during the present season, including chlorination works for the reduction of sulphurets.

Palomo.—We learn that very rich rock has been recently struck in the Palomo mine in lower Rich gulch. It is expected that the next clean-up will be huge.

NEVADA COUNTY.

You Bet.—*Transcript*, April 24th: The sale of the extensive hydraulic and cement mining claims and ditch property of Ed. Williams has been negotiated with Mallory & Stone and other parties at Gold Run, Placer county. The price to be paid is $55,000 and the bargain to be closed in 10 days.

Marietta.—Lindsey & Co., the owners of this mine on the South Yuba above Washington, propose increasing the capacity and improving the works. The ledge averages 12 feet wide and pays all round $20 to the ton. The company has opened the ledge and crushed enough rock to demonstrate the uniformity of the yield and size.

A Nugget.—A few days since a lump of gold, worth $40, was found in the Brandy Flat claims, near Washington, by Mr. Ferran.

A Specimen.—A. Isoard yesterday purchased a quartz specimen, valued at $250, from a Spaniard for $212.50. It was found this week near Omega and weighs 16 ounces.

Perrin's Mine.—This is yielding $30 rock, and gives employment to 30 men.

Rock Creek.—Same of 22d: A gold bar weighing 68 ounces, was brought to town yesterday, from the claims of Clingenspor & Co.

Sucker Flat.—Crary, O'Brien & Co. are burning powder at the rate of 1,800 kegs a week. On Monday they discharged 240 kegs, on Tuesday they put off a blast of 775 kegs, each time doing first rate execution, and they expected yesterday to be ready for another shot of 800 kegs.

Marcelus & Maltman.—*National Gazette*, 23d: Work in the tunnel has been suspended for some time, for want of giant powder. There is none in market. The tunnel is in 1,200 feet, and has about the same distance yet to run.

Specimens.—The Nevada Consolidated Mining Co. took out $250 in coarse gold from their ground sluice on Thursday, after a run of five days. Some of the specimens would weigh half an ounce.

Empire.—We find the following announcement of the new English Co. in the *Alta* of 16th: Empire Gold Mine, Limited—Capital £100,000 in £2 shares—to be fully paid up on allotment. The mine, a freehold, is situated in Grass Valley, California. The property has been brought into working order, and £63,700 has been expended on the works, the profit for the last year being £27,973. The purchase price is £95,000, of which £30,000 may be paid in shares.

Empire.—*Gazette*, 25th: Work at the mine was re-commenced this morning, under the superintendency of J. F. Nesmith. The mill will not be running for a week or ten days.

Badger.—This mine has been leased by a company. The machinery for the Essex is being erected at the Badger.

The ledge in the Idaho mine looks better than ever before.

Scott's Flat.—*Transcript*, 25th: Jacobs & Co. are doing well. Cobb, Baxter & Co., at the last clean-up, took out $2,300. A slide occurred in Holmes' claims a few days since, upon which they are now washing. Ashburn & Baker have been all winter washing out a slide, and have not been able as yet to advance upon the bank.

PLACER COUNTY.

The Grass Valley *Union* of 20th has talked with an experienced Nevada county miner who had just returned from the vicinity of Auburn and Ophir. He says it offers an inviting field for the prospector. The milling has heretofore been exceedingly crude, and would, he says, break a Grass Valley company.

The same says: We understand that on Wednesday last, one man on Austin's ledge took out $50 in an hour. The ledge is situated between Ophir and Newcastle, south of Auburn ravine.

PLUMAS COUNTY.

Indian Valley Mine.—Quincy *National*, April 16th: We are informed that the water engine, recently put up, works admirably.

SAN JOAQUIN COUNTY.

The *Alta* has a letter from Hill's Ferry, dated 18th, which notes the discovery and location in that neighborhood of a silver-bearing ledge from four to six feet wide.

STANISLAUS COUNTY.

Great Silver Excitement.—Tuolumne City *News*, April 22d: Some weeks since Mr. Newsom's discovery of silver in the Coast Range, in this county, was reported. It is now said that five miles north of this spot, in a direct line, parties have discovered "The Lost Mine." There is a tradition that a very rich silver mine was worked somewhere in the Coast Range by a wealthy Mexican years ago. However this may be, there are evident proofs of work having been done in the newly discovered ground. There are three shafts, now partially filled up. A trail is regularly graded in the mountain side for a mile. We have visited the spot, which is about 40 miles from this place, the last 10 miles over an exceedingly rough country. We found Mr. Keys, of Stockton, with a party of five men, engaged in cleaning out one of the shafts. Little can be known of the thing until these are opened. Claims have been staked off and recorded for two or three miles on the line of the work. The district is to be known as Rogers' district. For over 20 miles in length the mountain range is being prospected for silver.

The Stockton *Gazette* says that there has been a Stanislaus county legend that Mexicans a century ago took out fabulously rich silver ore somewhere in the neighborhood and shipped the bullion regularly to Mexico; the operation being finally stopped by the Indians. Much search has been made for this mine, for ten years past. The lucky man was Steve Rogers, who was hunting estray horses. The traces of two tunnels are visible. Ruins of log huts also, and of two arastras. The same reports a $480-assay of some of the croppings, and says that Stanislaus county is wild with excitement.

SISKIYOU COUNTY.

Mining Items.—Yreka *Union*, April 22d: The mill of Jones & Co., at the Forks at Humbug, is crushing quartz for Smith & Co., from the Knapp ledge....The miners on Humbug are busily ground-sluicing. At present there is a very good head of water, and the prospect is that they will get their claims in good condition for washing up....But little doing at Happy valley.

TRINITY COUNTY.

Northfork.—*Journal*, April 23d: William Ritterbush, on the hill, has very rich ground. We saw one pan tried—proceeds, $1.65. Just above the bridge, Herman Schlomer got $7.50 out of a prospect hole 6½ feet deep and 4 feet square on the bottom. Conrad Miller, just above Northfork, cleaned up, as the result of his last four days' work, three ounces and $7.50. The claim just opened by R. J. Holmes prospects as high as $20 to the pan.

Dutton Creek.—There is not much to chronicle. Lange completed the main ditch this week, but has another branch ditch to dig. He expects to have three sluice heads on the mines. The mines look as favorable as ever.

Junction City.—The miners are generally doing well, for the scanty supply of water. The claims of Haas & Hager is said to be paying enormously—one informant saying 50 ounces per week.

Arizona.

Mining Items.—Prescott *Miner*, April 9th: Three mills are now running in this vicinity, besides several arastras. The last clean-up at the Big Bug mill yielded $1,300. This amount was taken out in five days. Taylor & Co., who have been working Charter Oak ore, in a new arastra, near the head of the Hassayampa, cleaned up recently $57 to the ton. The Eureka is running on good ore, from the Pine Mountain lode. The Sterling is pounding away. A clean-up has not yet been made. Excitement runs high about the lodes recently discovered near Camp Date creek. Fred. Henry has found the "richest thing yet," in Walnut Grove district. It is a ledge of gold-bearing rock that prospects "viciously" for 300 yards. We saw a lot of the ore, Wednesday, that displayed more free gold than any in many a day. C. Y. Shelton, of Walker district, has just finished working eight tons of Mountain Jay ore, from which he got $36 per ton. The Vulture mill is doing remarkably well. News from the placers continues good.

British Columbia.

The *Colonist* says that Mr. Ogden, agent of the Hudson Bay Co. at Stuart's Lake Station, had forwarded to the office, at Victoria, one hundred and fifty ounces of gold dust, from Fitalle creek. Amongst the dust were a number of lumps of native silver, weighing from two to four bits each. This money was paid for provisions for a small party of prospectors. Already three hundred men had reached Victoria from different places; but Mr. Ogden says that the end of May will be time enough to reach the diggings, as by that time there will be no scarcity of provisions.

Colorado.

California Lode.—Central City *Register*, April 20th: This, with its extensions, are being worked for nearly a mile in length. One hundred and six miners are employed under ground. There are six whims and four engines used, and two more engines will soon be in place. The aggregate depth of the shafts is 2,700 feet, from which comes a weekly production of about 100 cords—600 to 700 tons—of stamp mill ore, yielding from three to twelve ozs. of gold per cord. At a low estimate of its assay value, this ore is worth from $12,000 to $15,000 in gold.

Items.—Fleming, Reiley & Sorden, on the "Irish Flag," report a pay vein of 18 to 24 inches, and a crevice of three to three and one-half feet. The quartz is yielding six ounces per cord. Work will be resumed in the Briggs mine to-day. Whitcomb's 12-stamper, is running steadily on "Flack" ore, for Storm & Co., and on Burroughs ore for Jolly & Co. Sparks & Fagan have shut down, having been delayed with water. Mr. Hardesty is building an eighteen-stamp mill in Nevada gulch. Two batteries—twelve 570-lb. stamps,—will be ready for duty in ten days. Joun Gray is working the Central Co's property on the "Gunnell," with a pay vein of two to eight inches. He sells first quality ore for $80 a ton. The second runs from four to six ounces per cord. Edward Jaques, of New York, will refit the Stoner mill. A new engine and boiler are on the way from Massachusetts. Bull & French are working the "White" lode. It has a shaft 70 feet deep. The crevice is about two and one-half feet wide, Jas. Wood is working the Butler. He has a shaft 95 feet deep. The whole vein matter—about two feet—has run as high as four and one-half ounces to the cord. J. W. Clayton is mining on Nos. 1 and 2 E. on the "Flag." He has an 80-foot shaft on No. 1, and is still sinking.

The Briggs mine netted in March $10,800. So says the *Herald*.

The Terrible Lode.—Georgetown *Miner*, April 14. The new company proposes to commence, June 1, the erection of dressing works, of twenty-five tons capacity. All first-class ore will be crushed and forwarded to England; the second and third classes will be treated at home. Smelting works, of large capacity, will be erected next year.

Clear Creek.—The same gives a list of the mills and smelting works in the county with the location and capacity of each. The number of establishments is 11, and the aggregate daily capacity is 110 tons.

Items.—Herring Tunnel is in 300 feet and being driven rapidly. The Magnet lode is now in rich pay. The Taft Bros., on the Comet, have struck a body of rich ore. An Eastern company will work the Junction lode. Griffith lode is in "bonanza." Work has been commenced on the Sterling. Pay ore struck again in the Equator. Another 300-foot contract let in the Marshall Tunnel. Work has been going on all winter in Darly district. Capt. Lyght has struck a large body of pay ore.

Summit County.—At Lincoln, Hoops & Blair, drifting and sluicing, have taken out $4 per day to the hand. At Salt Lick gulch, mouth of Ten Mile creek, Pat. Cassiday and others have been all winter taking out $5 per day to the hand. Peter Halsey and G. M. Parker have struck two large argentiferous ledges in Illinois gulch.

Idaho.

Loon Creek.—*World*, April 14th: Tassell, express messenger, arrived from Oro Grande on Saturday. From him we learn that mining operations have commenced in earnest, and that there is a great scarcity of laborers. It is now, and for several weeks will be, difficult to get through to Loon creek, on account of the softness of the snow. Meat has entirely given out at Oro Grande, but provisions of other kinds are abundant. Everybody contemplates a lively mining season. Wages are from six to seven dollars.

Mexico.

Guerrero.—Acapulco cor. of *Bulletin*, April 5th: A point of importance to this State of Guerrero is the discovery of extensive veins of precious ores, which keep the mining engineer of Tixtla busy making assays. A circular, published by said gentleman, says that the government is willing to make over to capitalists a number of mines, which yield at least two marks of silver per carga of 300 pounds of ore, on condition that the State should be allowed to reserve a few barras. In the district of Tabasco, close to this city, four rich mines have been discovered. M. Pedro Navarret, in the district of Miua, has opened 70 distinct veins, of which El Tesoro is the richest. He has made a collection of specimens to take to the United States and Europe, expecting to raise funds for working the mine.

Montana.

Radersburg.—Helena *Gazette*, April 11th: Mr. Keating has purchased the Posthlewaite 15-stamp mill, to be put up on the famous Keating lode. This lode's rock, in arastras, paid from $40 to $60 to the ton. There is now 900 tons of quartz out and 14 miners taking more out. The mill is expected to be ready in four weeks. Mr. Sample has purchased a 12-stamp mill, which will be erected on the Robert Lee lode. A number of hundred tons of rock now waiting. Quinn's branch ditch will be completed on the 20th. This brings water higher on the mines than ever brought before. One hundred men are wanted in Radersburg to work for wages.

Nevada.

COPE DISTRICT.

Gold.—Elko *Independent*, 20th: George Turney brought in $600 worth of gold dust. The ditch was completed Monday, and from this time regular shipments will be made.

Ore.—Five thousand pounds from the Oregon ledge came in Saturday, consigned to Oppenheimer & Co.

Mountain City Mine.—Same of 23d: Authentic advices report the mine looking better than ever. The whole body of ore within a width of five feet will average $800 to the ton. The company had ten tons of this ore on the dumps.

HUMBOLDT.

Galena.—*Register*, 16th: At a meeting of the owners of the Butte mine, Tuesday, it was decided to build a mill for the low grade ores. The Co. have derived sufficient funds from the proceeds of first-class ores shipped to build the mill.

The Stars and Stripes Co. will also build a mill at once.

Uncle John Atchison is on his way to Arizona. He left his mill and mining interests in Cope with friends. He is noted for having been among the first at every mining camp in the State.

Rumors.—Extravagant reports of the richness of quartz mines recently discovered 50 miles north of the Humboldt, in ranges south of Independence valley, are being circulated.

Battle Mountain.—Cor. of same: A shaft on the Buena Vista has disclosed $100-ore. A shaft is 75 feet deep on the Butte, shows a vein from two to six feet wide, which will average $150 to the ton. Veritas has a 95-foot shaft, exposing immense quantities of good smelting ore. The White mine is shipping $200-ore, and holding the second class for the completion of Bruce & Co's smelting works. The Shiloh sends its first class ore to San Francisco.

REESE RIVER.

Bullion.—*Reveille*, 20th: The Manhattan company shipped direct to New York, to-day, 34 bars of silver bullion, weighing 3,540 pounds, of the value of $24,212 93. During March, the mill produced $88,217.52.

Mineral Hill.—*Independent*, 20th: Curtis & Huber are laying the foundation of their mill, which will be one of the finest in the State, with all modern improvements, together with the Stetefeldt furnace. The shaft on the Giant ledge is down 53 feet, and the vein is nine feet wide.

WASHOE.

Ophir.—*Enterprise*, April 24th: No inconvenience on account of water in any part of the mine. The drifts at the 700-foot level are progressing satisfactorily. The north drift is in 47 feet and has 45 to go.

Hale & Norcross.—The new seventh station is completed, and drifting east through the vein commenced, The face is already in good ore. From the sixth level, 85 feet above, the winze is 62 feet deep and in good ore all the way. The daily yield is 170 tons.

Gould & Curry.—This mine yields 90 to 100 tons of ore per day, assay value, $54 per ton. Some very high grade ore, estimated to be worth $1,500 per ton, is found at this point, three or four tons being sacked up daily and send to the mill at Rono. Phil. Deidesheimer, formerly of the Burning Moscow, has been appointed Sup't.

Occidental.—This company levied an assessment of $6 per share, on Tuesday, amounting to $60,000. This is the first assessment ever levied.

Sutro Tunnel.—This now measures 978 feet. The ground is not quite so hard. The water is increasing.

Sacramento & Meredith.—The mill is progressing rapidly. It will probably be set at work by the middle of May.

Chollar-Potosi.—The daily yield is 200 tons, superior to that lately obtained. A large amount of ore has accumulated at the dumps. There is also a good supply at the mills.

Caledonia.—The face of the west drift at the 200-foot level is now 80 feet from the shaft, and is in hard blasting rock.

Yellow Jacket.—Gold Hill *News*, 23d: The new ore at the 900-foot level is looking better. The dirt north from the Crown Point, 75 feet beyond the south line. The daily yield is 350 tons.

Imperial-Empire.—The bottom of the shaft is in very hard blasting rock. The station for the 1,200-foot level is being opened.

Belcher.—Upper levels yielding 80 tons of $20-ore. The 730-foot level toward the south boundary of the mine is not of high grade.

Kentuck.—The daily yield still shows a falling off, and no new ore bodies are discovered.

Crown Point.—Upper levels yielding 75 tons low grade ore per day. The incline from the 1,000-foot station of the shaft is down 50 feet; rock favorable.

Overman.—Yielding 160 tons per day, all from the upper level. A connection was made with the old Mary Ann shaft last week at the 400-foot level.

WHITE PINE.

Review.—*News:* Mining is reviving. The rumor that English capitalists have purchased a number of the best mines on Treasure Hill and Chloride Flat, including the Eberhardt, has contributed to stimulate business. There is this healthy difference between this year and last, and that is the money now circulated is derived from the legitimate resources of the country. The Base Metal Range is putting in an appearance, as a mining region, that will furnish labor for thousands upon thousands. The shipments of bullion for the week ending April 18th, amount to $33,717—and of base bullion, 49,000 pounds.

Items.—The shaft in Crown Point No. 8, at the depth of 40 feet passed abruptly from almost solid galena into free chloride ore, assaying $125. A fissure vein has been opened in the Trench mine six feet wide at a depth of 33 feet, with $1,000 ore. Noonday has on dump 100 tons first class ore, and 200 second class. Montauk will be able to supply a 10-stamp mill as soon as the roads become good. Shoo-Fly has a shaft 24 feet down—20 feet of it through solid ore. Wabash supplies the Sheba mills with good ore. The Stanford mill started up with several hundred tons of ore at the batteries. Alsop smelting works have turned out 70 tons bullion since they started on the present run. The Shermantown works have 30 tons of bars at the furnace, worth $200 per ton. One hundred and two mines, by count, are now being worked in White Pine District. McIntosh and Barclay shipped on the 22d. from the White Pine Smelting Works, 20,290 pounds of base bullion.

Eberhardt and Aurora Mining Co. The capital stock is £300,000, in £10 shares, all of which have been subscribed. The price to be paid for the Eberhardt and Aurora South mines is £300,000, one-half in cash and the balance in shares—the latter to be retained until profits to the extent of £125,000 have been made. The property has been examined by the company's engineer, Melville Atwood, and by Thomas Philpots, acting agent.

Pogonip & Othello.—This ground has passed into the hands of a company incorporated under the laws of Illinois, with a capital stock of $1,600,000, divided into 1,600 shares of $100 each.

Outside Districts.—Morning Star, Freiberg District, has a 28-foot ledge of base ore of high grade. A brick smelted in a frying pan, assays $1,123 per ton in silver. The Shonte mine, has been sold to a Chicago company for $40,000. In Shoshone, the Indian and Illinois mines show an abundance of ore that will mill from $50 to $100 per ton without assorting. The Pittsburg mine gives assays as high as $1,200. Lexington bids fair to rival Ely. Silver Park is growing lively. Ely people are too poor to get away. In Eureka, the Champion mine has been sold to Ike. Bateman & Co., for $20,000. The Buckeye has 1,000 tons of ore out, which will work $100. Four furnaces are running in the district, and four more to be ready in 30 days.

New Mexico.

A Los Angeles telegram of 21st says: It is asserted that the famous silver mines are just within the limits of Arizona. Tucson capitalists have formed a company called the Mine Madre Mining Co. Rock taken at Paudon from the immense ledges at Burrow district is astonishingly rich. Miners and parties from California and all points are coming into Tucson.

Utah.

Snake River Mines.—Corinne *Reporter*, April 19th: Within a few days parties arrived from Snake river report prospects as flattering. Mr. Morrison states that diggings which pay $2 or $3 per day are common, but his party only work in the best eddy drifts, many of which are paying $25 per day, and few less than $15. There are 200 men at work within a distance of a hundred miles up and down the river, all within a 175 miles of Corinne.

New Incorporations.

The following have filed certificates of incorporation with the County Clerk, San Francisco:

Lloyd Patent Axle and Journal Co. April 22d. Capital stock, $500,000, divided into 5,000 shares. Trustees: George W. Smiley, George A. Lloyd and Anthony Rosenfield.

Merchants' Exchage Bank.—April 24th. Capital stock, $1,000,000; number of shares, 10,000. Trustees: Levi Stevens, J W. Ladd, N. P. Cole, J. M. Ryder, A. N. Coleman, P. M. Bowen, H. A. Crane, S. Hemenway and G. H. Wheeler.

Meetings, Elections, Etc.

White Pine Smelting Co.—April 20th. Trustees: D. D. Shattuck (President), E. D. Keyes and H. L. Hutchinson. J. J. Scotchler was elected Secretary.

Noonday S. M. Co.—April 25th: Trustees: J. D. Fry, M. J. McDonald, Geo. Congdon, O. H. Bogart and Louis Vesaria.

New Idria Quicksilner M. Co.—April 25th. Trustees: W. E. Barron (President), Thomas Bell, D. O. Mills, W. C. Ralston and William Burling. Edward Mickle was reëlected Secretary.

San Francisco Mining Stock Market.

The mining-share market continues quite active, notwithstanding the slight recession noticeable throughout almost the entire list. At present the strong speculative disposition, so recently one of the features of the market, is not nearly so apparent, and combinations to carry stocks up or down are, for the moment, without force. Outside stocks—by which we mean those not located on the Comstock lode—are getting to be a feature of our market, and, during the past week, a greater number have been offered, and larger sales have been effected than for a long time past.

We clip the following from the *News* of the 25th, with regard to the White Pine mines: "During the past week work has been pushed with renewed vigor in all the principal mines, while prospecting has been extensively carried on. We have no changes of importance to announce. The sale of the Aurora Consolidated and Eberhardt mines, to a London company, may be considered accomplished. The Aurora South has also been favorably reported on by the agent of another English company, negotiating for its purchase. Pogonip & Othello has been sold to a Chicago company, whose agent is daily expected here to commence work on the mine and prepare the foundation for a 20-stamp mill. A large number of base-metal mines, theretofore idle, were started up last week, and the District has never presented a more busy or prosperous appearance than at the present time. Our bullion shipments for the week foot up, $17,162 25 to San Francisco; $12,281 21 to New York—total, $29,443 46, and 48,790 pounds of base bullion."

Chollar-Potosi—has been well maintained, but sold to a less extent than during the previous week. The yield for the week ending April 22d amounted to 1,300 tons, showing an average assay-value, from car-samples, of $72 51 per ton; previous week, 1,400 tons—assay value, $70 19 per ton. At the south end of the stope, a marked improvement of ore, both in quantity and quality, is noticeable, and at a later date, this ore was increasing in width. In the entire Blue Wing section, a large amount of good ore is visible. At the first station of the new shaft 58 feet have been added to the branch drift running north, the face showing heavy clay. On the 26th inst., $32,964 in bullion was sent to the office, in this city.

Hale & Norcross—sold to a rather moderate extent, declining somewhat toward the close. On the 24th inst. the winze had attained a depth of 64 feet below the sixth level, the ore continuing to be of good quality, the assays for the week averaging over $100 to the ton. At the seventh station the north drift is now twenty-five feet north of the shaft. They are also running a cross-cut east from this drift, which is now 14 feet east of the latter drift. This cross-cut has not yet reached the east wall. Both of these drifts are in excellent ore, said to be of much better quality than the ore found in the winze now being sunk below the sixth level. For the week ending April 23d, 1,008 tons of ore were extracted, 331½ tons coming from the upper mine, and 676½ from the lower. They had on hand, at that date, 6,630¾ tons of ore, of which 2,565 tons is low grade. On the 24th inst., they received $30,424 in bullion.

Kentuck—has met with limited sale, at a recession. For the week ending April 22d, they extracted 303¼ tons of ore, showing a 65 per cent. assay value of $6,490 14, equal to $21 42 per ton; previous week, 355¼ tons, equal to $14 79 per ton.——Crown Point was pretty active. The ore yield for the week ending April 22d, amounted to 360½ tons, the 65 per cent. assay value showing $5,326 36, or $14 72 per ton.——Imperial was in the market to a considerable extent, at a slight recession. The southwest drift is again in clay, which has been penetrated, the face exhibiting very hard white barren quartz. A start has been made from the 1,200 foot station. They are getting some good ore from the Alta mine, but the vein being narrow, it comes out slowly.

Overman—has been sold at quite uniform rates. The estimated value of the crude bullion sent forward on the 23d inst. was $21,800. The cross-cut west, on the 226 level, running through the Mary Ann chimney, is reported to show some good ore. During the week, 1,221 tons of ore were extracted; previous week, 1,135 tons.

Savage—was in the market to a less extent, selling at a decline. Isaac L. Requa has been appointed Superintendent of this mine, in place of Charles Bonner, resigned.——Empire Mill levied an assessment of $10 per share, on the 22d inst.——Oriental (W. P.) levied an assessment of 20 cents per share on the 22d inst.——Metropolitan M. & M. Co. paid a divident of 50 cents per share on the 26th.——Original Hidden Treasure, (W.P.) will hold its annual meeting of stockholders on Tuesday next, 3d of May.—*Commercial Herald.*

San Francisco Prices of Copper Ores.

San Francisco, April 28, 1870.

W. T. Atwood states the following as approximate price at which copper ores can now be sold in this city. There is no sale for ores which assay less than 10 per cent.:

	Per ton.		Per ton
12 per cent. ore	$24 00	18 per cent. ore	$41 40
13 " "	26 65	19 " "	44 65
14 " "	29 40	20 " "	48 00
15 " "	32 25	25 " "	62 50
16 " "	35 20	30 " "	75 00
17 " "	38 25		

Ores assaying above 30 per cent., $2.50 per unit. Bars at the rate of 13c. per lb. for pure copper.

◆

Tea Culture.—The Sacramento *Reporter*, of April 14th, says: "We had the pleasure of a conversation yesterday with J. S. Harbison, who has just returned from a trip up the mountains, visiting *en passant* the Japanese colony of Herr Schnell at Placerville, El Dorado county. He speaks in glowing terms of the prospects of the little colony, and anticipates that Herr Schnell will come out ahead on his venture. About one hundred and ten acres have been laid out with over 200,000 tea plants or nuts, as they are more correctly termed, which look finely and give promise of a bounteous crop of savory teas. The Japanese, a race infinitely superior to the Chinese, are excellent agriculturists, and all the work on this plantation is done on purely scientific principles. As tillers, they have no superiors, being besides ingenious and capable in a hundred different ways. They are comfortably domiciled, and express themselves well satisfied with their situation. They like our people, and do not hesitate to say that the soil on which they are now at work is superior to that of Japan. A considerable quantity of mulberry trees have also been laid out, but as yet it is too early in the season to accomplish anything with the silk worms, which are now in the first stages of their existence. We further learn from Mr. Harbison, that his own bee trees have commenced to develop finely, the bees swarming in considerable numbers. It now depends altogether on the weather whether he will have a good harvest of honey or not."

◆

Statistics about Gold.—The production of gold from the mines in the United States was for the last two years $122,000,000, or over $60,000,000 yearly. It is a curious coincidence that as our indebtedness to Europe, comprising Government bonds and railway securities, is about $1,000,000,000, the product of our mines seems to be a special fund to pay the interest on an average of six per cent. per annum on this indebtedness. The production of gold throughout the world, from the discovery of America to 1843, had steadily increased to $34,000,000 per annum, which was the production for that year in the whole regions of civilization. In the year 1853, the yield was about $250,000,000, and has not been less than $200,000,000 any year since. The production of gold in the last twenty years has been double what it was for the two hundred years before, the progressive increase being due to the improvement in machinery for extracting the ore.

◆

Assaying.—We see that Mr. F. W. H. Aaron has succeeded Knight & Co. in the assay business at Marysville. Mr. Aaron has had a large experience and enjoys an enviable reputation. We doubt not that he will sustain the credit of this office, which is one of the oldest and best in the State.

Farming and Gardening.

COMMUNICATIONS for this department are solicited from all parts of the Pacific States and Territories.

Important to Wheat Growers.

Hon. Horace Capron, Commissioner of Agriculture, in a recent letter to Hon. B. C. Cook, of the National House of Representatives, gives some hints on wheat growing, which should be considered and acted upon by every grower of that cereal. We copy from the letter as follows:

1. *Deterioration from Imperfect Seed.*—Regard must be bad to pedigree in wheat, as in cattle or horses, or the deterioration is sure to result. Among wild herds the prevailing law of the strongest aids in preserving its average excellence; but the prevalent neglect of the selection of seed of cereals is a sure means of degeneracy. Seed is generally taken at random, often an inferior and imperfect quality, because No. 1 wheat commands a higher price in market. Like produces like, and this shrivelled grain tends to slow growth in the plant, to late ripening, and consequently greater risk of insect ravages; it is immature and lacking in vitality, and decreased plumpness and diminished weight may be expected in the harvest; it may have germs of mildew affecting it, with insufficient vitality to resist the attacks of fungoid enemies.

2. *Deterioration by In-and-in Breeding.*—The use of the same seed year after year undoubtedly tends to deterioration, on the well-known principle holding in animal reproduction.

3. *Neglect of Rotation in Crops.*—On the richest wheat soils, with continued cropping, even with change of seed and careful selection, a diminished yield is usually apparent after the second crop. Illinois, Minnesota, California, Australia,—every famous wheat section known, attests the certainty and rapidity of decreased production under a practice which disregards rotation.

4. *Deficient and Careless Cultivation.*—As a rule, the only preparation for seeding is a slight scratching of the soil, sometimes only a harrowing of the weedy, grassy, uneven surface from which corn has just been cut; and weeds have thus an equal or superior opportunity for growth, and eventually smother and dwarf the wheat, furnishing a prolific cause for deterioration.

The wheat plant is susceptible of great improvement if the same judgment and care is exercised as is exhibited by successful breeders of farm animals. It will also degenerate with wonderful facility under the average management of pioneer wheat-growers. After this careless culture becomes unprofitable, and probably not until then, will the requisite means for improvement be used. Is it not now time to commence such improvement in Illinois?

OLIVES IN SANTA BARBARA.—According to the Santa Barbara *Press*, olives make a fine growth in that county without irrigation. On the fine hillside, a southeastern slope lying in plain view of town on the north, is the young olive orchard of Fernald, Blanchard and Towle. Although so much exposed to the sun, none of the trees are irrigated. The plow does the work. Results are gratifying. They have trees four years from the cutting which are seven inches in circumference. They also have some 500 bearing almond trees—next year will have 2,500. They have likewise 200 English walnut and 10,000 vines of choice table grape varieties. All are doing well, and without irrigation.

THE BANANA.—This fruit is doing well in Florida. It bears in three years from the offshoot. Complaint is made, however, that of the great variety which exists in other countries, two only have been introduced into that State. There is a great demand for the plants there, much beyond the supply. Persons who desire large numbers can get only three or four, and are compelled to wait for their increase. Quite too little attention is being paid to the cultivation of this valuable fruit in California.

THE INDIA-RUBBER TREE.—Mrs. Harriet Beecher Stowe is cultivating the india-rubber tree on her plantation in Florida.

The Uncertainties of Farming and How to Avoid Them.

One of the great causes of uncertainty in farming operations grows out of the fact that the farmer depends less for his results upon forces under his own control, than does the manufacturer or artisan. Moreover, the farmer encounters more hindrances in the way of changing his products suddenly, as the price of any particular commodity may go up or down, than obtains with most avocations. He must arrange at least a year beforehand for most of his crops, and the ones which at the commencement of the year promise best, often promise least before the year is half expired. He has to "go it blind" to a very great extent. One year a good crop of wheat is profitable. The next year the market is overstocked by large crops, which affect his market, though grown, perhaps, thousands of miles away. One year the seasons are favorable; the next, the rust, mildew, blasts, drouth or insects destroys his anticipations. He can never tell what is to be a lucky or which an unlucky year. Too often he sows with sublime faith to reap in direst sorrow. Truly, says one, "The farmer is a man of sorrows and disappointments, from the beginning to the end, and farming is an uncertain occupation."

While there is much in all this that cannot be avoided, much may also be overcome by judicious management and careful calculation. The great mistake, and the one most general in this country, is the disposition to venture everything on a single chance. A prudent merchant never ventures his all in a single ship—he distributes his chances. But all wheat, all barley, all fruit, all roots, all stock or no stock, is generally the rule in California, and it is a poor rule. Diversified farming not only distributes the chances in the market; but secures a higher order of cultivation—instead of deteriorating the land and crops, it improves both.

Another trouble, too common with farmers, grows out of the fact that they utterly fail to keep any account with the farm. They don't know the cost of raising this or that crop, and of course they are unable to arrive at the comparative profit or loss thereof. Now a farmer should know, to a certainty, what each field or patch of wheat, barley, potatoes, corn, flax, etc., costs, per bushel or cental. He should note as accurately as may be, how much this or that field has improved or run down,—within the last or any past term of years. Careful accounts should be kept of everything bought for or sold from the farm. If no other benefit is derived therefrom, the habit of care and thought engendered by such a practice will more than pay for all the extra trouble.

Every farmer should take an agricultural paper to aid him in the practice of his labors. It is there he finds the condensed experience of the age. Every intelligent farmer in the land is, through the agricultural press, made his friend and neighbor, with whom he may consult and compare experience. The present is an age of progress—progress in everything. It is impossible for a farmer to take and read for one year a good agricultural paper without being benefitted many times the amount of its cost. Every careful thought, every well-considered word or action of our lives, if spread before the world, is as seed sown upon good soil, which will grow up to be a use and joy forever. The newspaper—we mean, of course, the really useful paper—is the great vehicle for the spread of modern thought—the great reservoir of progressive knowledge. Knowledge, carefully applied, is the lever with which the farmer may successfully grapple with even the usually uncontrolable forces of Nature. Knowledge of his business will enable him to render one of the naturally most uncertain avocations, as sure as any calling in which man can engage.

Diseases of the Horse—No. 3.—"Stifle."

Not having received any reply to our query asking for the proper mode of treating "stifle," we subjoin that of our correspondent who suggested the query, with some other general remarks of our own. We take the liberty of saying that our correspondent, Mr. S., is a nephew of Mr. B. P. Shillaber (Mrs. Partington), and, of course, cousin to the well-known genius "Ike." Mr. S. writes, under date of March 3d, as follows:

I got a colt stifled, a week ago, and knew not what to do. I made many inquiries; but of the many, I met but one who said he could cure it. I consulted Youatt and Stewart; but neither give the simple cure which the case admits of.

The man who knew of it chanced to be working for me, and I gave him permission to try his plan.

He first placed ropes, well covered with sacks, from one side of the stable to the other, passing under the colt and well secured upon both sides. He next wrapped cloth about the well leg, between the fetlock, and then tying a rope, thus raised the well leg from the floor, fastening the rope to a beam overhead. This brought the weight of the animal upon the stifled leg, when the patella assumed its natural position. That being done, he fomented with a liquid made by boiling the inside of white oak bark in water until it became quite black. He did this five times the first day, about ten minutes each time. In twenty-five hours he let the well leg down, and the cure was effected. He, however, continued the fomentations for two days longer, and then let the colt go. In three days the animal was as well as ever.

The object of the ropes under the animal is to allow him to rest whenever he becomes too tired to stand on one leg. The position is not the best, but it gives him rest for a short time, until becoming uncomfortable in his unnatural position, he again gets upon the leg which is diseased.

Many persons may know of this, or of a better mode of treatment; but I would have given much to have known this the morning the accident happened. Now, Mr. Editor, I thought that by asking a question now and then, the replies will surely give us some information. Ask, if you please, "what is the best method to cure stifle?" and if you get no better than this, you are at liberty to publish what I have written, and I, myself, certainly, and I presume others of your readers would like to hear something, in addition, from you, on a subject about which the books within ordinary reach say so little.

I take great interest in your farming department, and read every word carefully. Wishing you every success, I remain, yours truly, CHAS. E. SHILLABER.

Cordelia, Solano county, Cal.

Remarks.

Colts, under certain conditions, as when they are laboring under a faulty state of the nutritive functions, are often troubled with the "stifle." The lack of proper digestion, or the feeding of improper food may induce it. The stifle joint is not often subject to sprain. A faulty state of the nutritive functions, in a growing animal, interferes with the healthy building up of the bones throughout the system, and is often especially manifested in the bone pulley and ligaments over which the patella plays, by the appearance of incipient ulceration. Under such circumstances, the animal must be fed upon the most nourishing diet, and should take with his daily food, or otherwise, a drachm each of carbonate of iron, phosphate of soda and powdered gentian. He should be well cared for and protected from undue heat, cold, moisture, or draft, and should stand on an even floor. In extreme cases, a succession of blisters should be employed as counter-irritants, applied directly over the stifle joint, each succeeding one to be applied as soon as the skin is left clean of scab from the preceding one. As a blister, a compound of one ounce of powdered cantharides, half an ounce of oil of origanum and fifteen ounces of spirit of wine may be rubbed over the joint, repeating until the desired effect is produced. Milder treatment may answer in ordinary cases. Care must also be taken to keep the bowels in good order; nitre may also be required for the proper regulation of the urinal functions. Of course, under such circumstances, a good veterinary practitioner should be consulted.

Milder Cases.

A laxation or slipping of the patella bone sometimes occurs without any special disease of the bone or system—simply from a too great laxity of the muscles which hold it in place. This also is much more common among colts than among full-grown animals, and is generally produced from causes similar to the above. The muscles are not properly nourished, although the bone itself may be unaffected. The remedy, in such cases, is to slip the bone back in place, and apply persistent bathing; the bath employed in the case described by Mr. S. is no doubt as good as any—the object being to *contract* the ligaments which hold the bone. Various methods are employed for putting the bone in place; that employed in the case alluded to is probably as good as any for the case then in hand. The animal should be fed on the best and most substantial food, so as to most readily and thoroughly build up his system and make him strong in muscle. Mild cases of this kind, which right themselves, as they sometimes do, are often taken for *cramp*.

A Sprained and Dislocated Stifle.

As has been already said, the stifle joint is not often subject to sprain. The only allusion to any medical or surgical treatment of the stifle mentioned by Youatt in his work upon the horse, is in reference to cases of this kind, and reads as follows:

The stifle joint is not often subject to sprain. The heat and tenderness will guide to the seat of injury. Occasionally, dislocation of the patella has occurred, and the horse drags the injured limb after him, or rests it on the fetlock; the aid of a veterinary surgeon is here requisite. The muscles of the inside of the thigh have sometimes been sprained. This may be detected by diffused heat, or heat on the inside of the thigh above the stifle. Rest, fomentations, bleeding and physic will be the proper means of cure.

INFLAMMATIONS, ETC., ON HORSES.—For all strains, wrenches or contusions, when the skin is not broken, hot fomentations of vinegar and water, applied by means of flannel bandages, frequently renewed, are the best possible treatment. Where there is much swelling and acute inflammation, linseed, turnip or carrot poultices may be applied with advantage, and the parts should be kept tightly bandaged, when not under other treatment. If the case is one of lameness, and the disability continues after the swelling and inflammation have past, the part should be wrapped with a close, but not tight bandage, saturated with cold water.

PRICES IN OLDEN TIMES.—In the "good old times," before the discovery of America, money was so scarce that the price of a day's work in England was fixed by an act of Parliament in 1351 at one penny. At that time twenty four eggs sold for one penny, a pair of shoes for four pence, a hen for a penny, and a fat ox for six shillings and eight pence. So that, in those days, a day's work would buy a hen or two dozen of eggs; two days work would buy a pair of shoes; and a fat ox cost eighty day's work. On the whole, human labor brought in the average about half as much food and perhaps one-fourth as much cloth or clothing as it now does.

MEDICAL PROPERTIES OF CELERY.—A correspondent of an Eastern agricultural paper says: "I have known many men, and women too, who, from various causes, had become so much affected with nervousness, that when they stretched out their hands they shook like aspen leaves on a windy day—and by a daily moderate use of the blanched foot-stalks of celery leaves, as a salad, they became as strong and steady in limbs as other people."

HOW TO DETERMINE A COW'S TEMPER.—Some one says a cow's temper can be determined by breathing in her nose. When you have breathed a few times in her nostrils, if she is kind, she will hold up her nose; otherwise she will catch it away.

Grape-Growing Near the Coast.

Mildew.

Within a few years several grape crops in Alameda and Santa Clara counties have suffered seriously from the effects of mildew; in some cases resulting in entire loss to whole vineyards. Under the influence of the cool sea breezes, damp atmosphere and fogs that prevail throughout the lands bordering on the bay, grapes are much more subject to the attacks of this fungus than are those grown among the interior valleys and hills; although I have known it to attack grapes grown on the damp river bottoms in the Sacramento Valley and even among the foot-hills of the Sierras, in localities exposed to excessive dampness from copious irrigation and shaded by trees. But everywhere in California, beyond the reach of sea damps, where the air is warm and drying, and the land dry and elevated above the overflows, grapes never mildew, but are excellent. Hence it is readily inferred that mildew on grapes is occasioned by excessive moisture, by cool damp air and the want of sunshine. Under favorable conditions grapes are a sure crop, where the blight sometimes ruins all. And it is a matter of no small moment to the owners of vineyards within the limits of its ravages to insure their crop of grapes against the effect of mildew. By my own observation, and from reliable information obtained of grape culturists, I am convinced that vines planted a liberal distance apart,—say seven or eight feet,—are much less liable to suffer than where grown closer together. Also, that the *surface* soil around and under the vines should be thoroughly loosened up and dried out; and that it is better to train the vines close to the ground than to raise them above it. The bunches of grapes that lay upon the dry earth, sheltered by the spreading leaves, are less liable to mildew than when the vines are elevated upon stakes and arbors.

Exposing the fruit to the sun, either by trimming off the leaves, or by shortening in the vines, is worse than useless. The evaporation of the surplus juices of the vine—*a matter of vital importance*—as well as the complete maturity and ripening of the fruit, depends upon the *leaf surface* exposed to the sun and air. The leaf is not only the lung but the stomach of the plant. It has the opposite effect intended, when vines and leaves are cut away in summer, to forward and perfect the fruit, yet nine in ten persist in doing it. Sometimes, when a great abundance of second growth lateral shoots crowd the inner space about the bunches of fruit, it is good policy to cut such side-growth out. But the *cutting back* of the *main vine* gives a tendency to produce these superfluous laterals, through the effort made by the vine to reproduce the leaf surface so essential to health and full maturity. In moist, deep, rich soils, where the vine makes wood too abundantly to fruit well, *spring pruning, to bleed the vine*, will correct the habit, and induce fruitfulness; just as root pruning of fruit trees of too vigorous growth will check it and cause mature fruitfulness. To cut back the branches will produce the opposite effect!

Sulphur a Perventative of Mildew.

Many experiments have proved this assertion. A timely and proper application will insure the grape against mildew. It is advisable to apply it as soon as the fruit buds are formed—the sulphur to be pulverized and dusted on the vine thoroughly, and again when the blossoms are full. The sulphur should be applied in every case when the vines are wet with dew and fog.

It is better to destroy the sporules of the fungus, than to wait until the same is grown on to the fruit. When applied to the fruit, the sulphur will destroy the mildew, but it also greatly injures the flavor of the grape by adhering to it.

It is as expedient, and quite as sure, to sulphur the blossoms as to sulphur the fruit. But it is the truth we wish to arrive at—the best way is always the best. Let every culturist experiment in various ways and *note results.* S. H. Herring

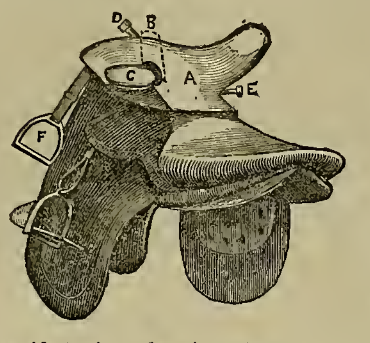
Jersey cattle are increasing in popularity in the East.

Improved Side-Saddle.

Among other California inventions, we present an illustration of one which will be of interest to our lady readers. Here in this State the gentler sex are quite famous as equestriennes, and the improvement comes naturally from a California lady.

In the figure, A represents the horns which slide from front to rear, or the reverse, increasing or diminishing the size of the seat of the saddle at will, making a seat fitting persons of all sizes, and allowing them to change their position at any time for an easier one, by simply turning the thumb-screw. The dotted line, B, shows the position of the horn when erect for riding, and C shows it as dropped for dismounting. D is the lever to move from one side to the other, in order to drop or raise the horn; E is the thumb-screw for fastening the horns in the desired position. This dropping the horn obviates the danger of catching the dress when dismounting, and not only prevents the garments from being torn, but may also be the means of preventing serious injury to the person of the owner. There is an additional stirrup, F, for the right foot, if the leg becomes benumbed or tired in riding long distances.



This saddle is as cheap as the common side-saddle is, we are informed, coming very extensively into use, and is rapidly superseding the old forms. The horns can be riveted to any saddle tree. The inventor is Clara A. Bartlett, of Stockton. Any further information may be obtained from the general agent, F. F. Houghton, 310 and 312 Clay street, San Francisco.

A Honey Extractor.—It is estimated that from fifteen to twenty pounds of honey are consumed by bees in the production of a single pound of comb; hence the great importance of carefully extracting the honey and returning the comb to the hive, whereby the yield of honey is greatly increased. Many plans have been devised to accomplish this end; but generally with very poor success. A machine has recently been devised in Germany, however, which is said to work admirably. It is called a *Smeloctore*—literally translated, a "honey-slinger," which exactly describes it. The comb is simply placed in a convenient rest or frame and made to revolve with such velocity, within a proper receptacle, as to "sling" all the honey out from the cells. This it is said to do without disturbing or harming any young brood which may occupy a portion of the cells subjected to the "slinging" operation. An American, named Peabody, the same person who invented the famous Peabody rifle, has also invented and patented a machine, which operates on the above principle, and is said to possess some advantages over the German device. This machine is figured and described in a late number of *Colman's* (St. Louis) *Rural World.*

Potato Sugar.—At a recent meeting of the Lyceum of Natural History, New York, specimens of syrup and of sugar made from potatoes were exhibited. It was asserted that syrup and sugar can be made at a low cost from the refuse of potatoes after undergoing distillation to obtain spirits. Potato syrup, it is reported, is used extensively by confectioners, and that the sugar has been introduced into the manufacture of lager beer. A factory, it is stated, has recently been established in Brooklyn, and potato sugar is produced in large quantities.

What I Know of Farming—No. 15.

Plowing—Good and Bad.

There are so many wrong ways to do a thing to but one right one that there is no reason in the impatience too often evinced with those who contrive to swallow the truth wrong end foremost, and thereupon insist that it won't do. For instance: A farmer hears something said of deep plowing, and, without any clear understanding of or firm faith in it, resolves to give it a trial. So he buys a great plow, makes up a strong team, and proceeds to turn up a field hitherto plowed but six inches to a depth of a foot; in other words, to bury its soil under six inches of cold, sterile clay, sand, or gravel. On this, he plants or sows grain, and is lucky indeed if he realizes half a crop. Hereupon, he reports to his neighbors that deep plowing is a humbug, as he suspected all along, but now he knows, for he has tried it. There are several other wrong ways, which I will hurry over, in order to set forth that which I regard as the right one.

Here is a middling farmer of the old school, who walks carefully in the footsteps of his respected grandfather, but with inferior success, because sixty annual harvests, though not particularly luxuriant, have partially exhausted the productive capacity of the acres he inherited. He now garners from fifteen to thirty bushels of corn, from ten to twenty of wheat, from fifteen to twenty of rye, from twenty to thirty of oats, and from a ton to a ton and a half of hay, as the season proves more or less propitious, and just contrives to draw from his sixty to one hundred acres a decent subsistence for his family; plowing, as his father and grandfather did, to a depth of five to seven inches; What can deep plowing do for *him?*

I answer—By itself, nothing whatever. If in every other respect he is to persist in doing just as his father and his grandfather did, I doubt the expediency of doubling the depth of his furrows. True, the worst effects of the change would be realized at the outset, and I feel confident that his six inches of subsoil, having been made to change places with that which formerly rested upon it, must gradually be wrought upon by air, and rain, and frost, until converted into a tolerably productive soil, through which the roots of most plants would easily and speedily make their way down to the richer stratum which, originally surface, has been transposed into subsoil. But this exchange of positions between the original surface and subsoil is not what I mean by deep plowing, nor anything like it. What I *do* mean is this:

Having thoroughly underdrained a field, so that water will not stand upon any part of its surface, no matter how much is deposited, the next step in order is, to increase the depth of the soil. To this end, procure a regular sub soil plow of the most approved pattern, attach to it a strong team; and let it follow the breaking-plow in its furrow, lifting and pulverizing the sub soil to a depth of not less than six inches, but leaving it in position exactly where it was. The surface-plow turns the next furrow upon this loosened sub soil, and so on till the whole field is thus pulverized to a depth of not less than twelve inches, or, better still, fifteen. Now, please remember that you have twice as much soil per acre to fertilize as there was before; hence, that it consequently requires twice as much manure, and you will have laid a good foundation for increased crops. I do not say that all the additional outlay will be returned to you in the increase of your next crop, for I do not believe anything of the sort; but I *do* believe that this crop will be considerable larger for this generous treatment, especially if the season prove remarkably dry or uncommonly wet; and that you will have insured better crops in the years to come, including heavier grass, after that field shall once more be laid down; and that, in case of the planting of that field to fruit or other trees, they will grow faster, resist disease better, and thrive longer, than if the soil were still plowed as of old. (I shall insist hereafter on the advantage and importance of subsoiling orchards.)

Take another aspect—that of subsoiling hill-sides to prevent their abrasion by water:

I have two bits of warm, gravelly hill-side, which bountifully yield corn, wheat and oats, but which are addicted to washing. I presume one of these bits, at the south-east corner of my farm, has been plowed and planted not less than one hundred times, and that at least half the fertilizers applied to it have been washed into the brook, and hence into the Hudson. To say that $1,000 have thus been squandered on that patch of ground, would be to keep far within the truth. And, along with the fertilizers, a large portion of the finer and better elements of the original soil have thus been swept into the brook, and so lavished upon the waters of our bay. But, since I had those lots thoroughly subsoiled, all the water that falls upon them when in tillage sinks into the soil, and remains there until drained away by filtration or evaporation; and I never saw a particle of soil washed from either save once, when a thaw of one or two inches on the surface, leaving the ground solidly frozen beneath, being quickly followed by a pouring rain, washed away a few bushels of the loosened and soddened surface, proving that the law by virtue of which these fields were formerly denuded while in cultivation is still active, and that deep plowing is an effective and all but unfailing antidote for the evils it tends to incite.

We plow too many acres annually, and do not plow them so thoroughly as we ought. In the good time coming, when steam shall have been so harnessed to a gang of six to twelve plows that, with one man guiding and firing, it will move as fast as a man ought to walk, steaming on and thoroughly pulverizing from twelve to twenty-five acres per day, I believe we shall plow at least two feet deep, and plow not less than twice before putting in any crop whatever. Then we may lay down a field in the confident trust that it will yield from two and a half to three tons of good hay per annum for the next ten or twelve years; while by the help of irrigation and occasional top dressing, it may be made to average at least three tons for a lifetime, if not forever.—*Horace Greeley.*

Something New in the Cultivation of Corn. We find the following in the St. Louis *Journal of Agriculture.* The idea may be productive of much practical good: An intelligent and reliable neighbor of ours, who has for many years been making experiments with corn, has discovered an importance and value in replanting corn, which is quite novel and worthy of publication. We have always thought that replanting corn was of little consequence, but this gentleman says: "it is of so much consequence he replants whether it is needed or not—or rather, he plants two or three weeks after the crop is planted, a hill about every fifteenth row each way." He says: "If the weather becomes dry during the filling time, the silk and tassel both become dry and dead. In this condition, if it should become seasonable, the silk revives and renews its growth, but the tassel does not recover. Then, for want of pollen, the new silk is unable to fill the office for which it was designed. The pollen from the replanted corn is then ready to supply the silk, and the filling is completed." He says nearly all the abortive ears, so common in all corn crops, is caused by want of pollen, and that he has known ears to double their size in this second filling.

Large Cranberry Field.—Washington Territory boasts of an immense cranberry marsh, yieldind 100,000 bushels in a single crop.

A NEW BANK.—We would call the attention of our readers, most especially those interested in the mechanical and industrial pursuits, to an advertisement in our columns, of the Merchants' Exchange Bank of San Francisco, for subscriptions to its capital stock. The following advantages are claimed for this incorporation: That it will be conducted on the same principles as govern our best Eastern banks, and is strictly a people's bank, intended to further all of the industrial pursuits of the coast. Its by-laws are simple and liberal. Its nine Trustees or Directors are made a Finance Committee to pass on all paper. Its terms of subscription are extremely liberal. Its incorporators are business men of good repute and integrity and men of the people. It is intended to meet one of the great wants of the business community where men of small means can be accommodated. We wish its projectors success. We learn that more than half of its capital was subscribed for the first day the books were open.

◆

J. A. VEATCH.—A telegram from Portland, Oregon, brings us intelligence of the death of Prof. J. A. Veatch. Prof. Veatch was a member of the Masonic and several other orders, and always maintained a high position among his friends and acquaintances. He was formerly a correspondent of the SCIENTIFIC PRESS, and his letters were full of interesting and important matter. His death entails a heavy loss on the community where he resided.

◆

IMPORTANT TO MILLMEN.—A new article to be used in the amalgamation of gold and silver ores, in the place of cyanide of potassium, is the cyanide of sodium, now introduced into the market by Falkenau & Hanks, of the Pacific Chemical Works. The principal advantages of the new preparation are claimed to be its reduced cost and its increased strength, it being made as concentrated as possible.

◆

THE PNEUMATIC BURRING MACHINE.—Dr. Beers, 109 Montgomery street, the well known dentist, has been using for several months this machine, of which we made notice last month, and informs us that it gives great satisfaction. He thinks that it will come into general use for dental purposes.

The Montana Immigrant Association.

A couple of weeks ago we received the circular of this Association, whose object is to prepare and publish, for free circulation, such information concerning Montona as shall encourage immigration to that place. The circular contains considerable matter of interest and also the announcement that "the Association does not propose to engage in buying and selling either public or improved lands, or lands of any kind," which in these days is an assertion worth noticing.

We hope that the efforts of the Association may continue in the direction and manner indicated and be crowned with success. The Territory offers fine inducements for good working men who are willing to depend on their own efforts for a livelihood. The agricultural capabilities of a large part of the land are undoubtedly very fine, and the completion of the Northern Pacific Railroad will bring a market to the door of the farmer. The facilities for stock-raising are especially good, and we believe that to this the Territory will look principally for many years to come. Timber exists in great abundance, and good bituminous coal is found in many places. Limestones and sandstones occur everywhere, of quality proper for building purposes. Iron ore is reported in great quantities, but is not worked as yet. The other metals are frequent, and the yield from the gold placers this year will amount, according to the opinion of many, to 25 or 30 millions. These and other inducements will no doubt bring many immigrants, certainly, when the railroad is built.

◆

New Iron Mines in Maine.

The Boston *Advertiser* contains a description of these mines, which were lately discovered at Trescott, Maine. The quality of the ore is said to be very good, and three tons, crushed, sampled and assayed, gave 64.05 per cent. of iron with considerable lime and manganese. It is extremely soft and friable, requiring but little power to pulverize it, and smelts readily.

The deposit has a course northeast and southwest, and can be traced a mile in length and several hundred feet in width. "About two miles across Cobscoat Bay, in a straight line on the course of this vein or deposit, you strike the narrow point of a promontory. This rises abruptly from the water in a perpendicular cliff about 100 feet high, and presents upon its face, for the distance in width of a quarter of a mile, an almost unbroken body of iron ore, varying in richness from the highest point which science recognizes, down to the leaner grades of ores, but nearly the whole mass is susceptible of being worked in cupola furnaces into pig-iron. This cliff is without doubt the *hanging picture* above groump of the mine at Trescott and underground a continuation of the same.

There are required but one hundred bushels of charcoal to the ton of ore in smelting, while other ores, particularly the harder ones of Iron Mountain, require about one hundred and sixty bushels. There are patent furnaces now being erected at Eastport for the working of this ore. The intention is, for the present, to make iron blooms for steel, but there is ore enough to supply three or four such works."

◆

ORES AT SALT LAKE.—Mr. John Cunnington, of Salt Lake City, advertises in the *Mormon Tribune* that he is prepared to purchase lead or silver ores in quantities of two tons and upwards, for which the highest price will be paid. These ores, we presume, are purchased for shipment. Mining is fast becoming an important industry in Mormondom.

◆

"HOW CROPS FEED."—We have received a copy of this valuable work from A. Roman & Co., and shall notice it, at length, next week.

◆

ALAMEDA FLOWERS.—We have received a fine boquet of choice roses and flowers from the garden of Rev. Mrs. Wm. Taylor, of Alameda.

A Full List of Patents Issued to Pacific Coast Inventors.

[FROM OFFICIAL REPORTS TO DEWEY & CO., U. S. AND FOREIGN PATENT AGENTS, AND PUBLISHERS OF THE SCIENTIFIC PRESS.]

FOR THE WEEK ENDING APRIL 12TH.

HAIR MEDICINE.—Andrew J. Fletcher, Red Bluff, Cal.

FOR THE WEEK ENDING APRIL 19TH.

WATER-PROOF COMPOUND FOR BOOTS AND SHOES.—Martieu H. Böttger, Sacramento City, Cal.

CAMERA-STAND.—William W. Dames, San José, Cal.

DENTAL APPARATUS FOR CASTING PLATES FOR ARTIFICIAL TEETH.—James Alanson Loomis, Carthage, Ill., and Charles Frederick Moll, San Francisco, Cal.

MACHINE FOR ROLLING CONICAL AND OTHER TUBES.—Charles Kewen, San Francisco.

KNOB FOR SAFE DOORS.—Joseph G. Kittredge, San Francisco.

PISTON-ROD PACKING.—Harvey Thomas Lee, Marysville, Cal.

SCREEN ATTACHMENT FOR WINDOWS.—George Reed, William C. Hoagland and John J. Newson, Brooklyn, Cal.

AMALGAMATOR.—Chas. C. Stevenson, Gold Hill, Nevada.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & Co., in the shortest time possible (by telegraph or otherwise), at the lowest rates. All patent business for Pacific coast inventors transacted with greater security and in much less time than by any other agency.

◆

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co's Scientific Press American and Foreign Patent Agency, the following are worthy of mention:

MACHINE FOR ROLLING CONICAL AND OTHER TUBES.—C. Kewen, S. F.—This machine is intended for rolling conical tubes or funnels from sheet metal of any kind, and is more particularly useful for forming locomotive smoke-stacks where they are made conical in shape. It consists of two series of adjustable rollers placed at a short distance apart, and a third series, also adjustable, placed above the space between the first two series. The lower series are revolved by the friction of a revolving elastic table beneath them. The sheet metal is placed so as to roll under the upper series and over the lower ones, by its contact causing the upper ones to roll also, and thus feed the sheet metal while it gives it the proper form. By the use of this device, locomotive smoke-stacks can be made with very little trouble, and for tinsmiths the device will be of great value. The rollers may be removed, replaced or adjusted with great facility, and thus adapted for rolling tubes of almost any description.

PISTON-ROD PACKING.—H. T. Lee, Marysville, Cal.—This is an improved manner of constructing metallic packing-rings for piston rods and valve stems, and is a device easily adjustable at any time, requiring but a few moments for attachment. It consists of two beveled or conically shaped rings, which clasp the piston rod or valve stem inside the cage of the stuffing box, one of the rings fitting directly against the rod and having its beveled edge towards one end of the space, while the other ring faces it, as it were, so that its bevelled side clasps the outside of the first ring. When the gland or follower is screwed down against this packing, the last-mentioned ring is forced farther over the inner one, causing it to clasp the rod more tightly, while the outer one is forced against the outside of the cage, thus making a tight joint. The rings are both made in pieces, so as to admit of the necessary compression and expansion.

AMALGAMATOR.—C. C. Stevenson, Gold Hill, Nevada.—This amalgamating pan has been previously described and illustrated in the SCIENTIFIC PRESS, and needs, therefore, no further full description. Our readers will remember that the principal points were the inclined wings or guides shaped somewhat like the mold-board of a plow, and the covered openings or housings on the upper surface, at the inner periphery of the muller, by which construction a nearly level surface of the pulp is secured, the whole mass is effectually subjected to the grinding and amalgamating process, while the pan works very easily and allows of large amounts being operated on at once. The severe tests to which the pan has been subjected, in competition with others, at Gold Hill, have turned out very satisfactorily to the inventor, who is a millman of very considerable experience.

SCREEN ATTACHMENT FOR WINDOWS.—G. Reed, W. C. Hoagland and J. J. Newson, Brooklyn, Cal.—This device, for the purposo excluding insects, etc., is so arranged that the frame of the screen is continuous with the window frame above and below, and when not in use passes into a boxhead or sill, as the case may be, so as to be entirely out of sight. Moreover, to the meeting rails a guard is attached, so that when the window is opened, the space between the glass of one sash and the rail of the other will not admit any insect. The whole forms a very neat and ingenious device.

CAMERA STAND.—W. W. Dames, San José, Cal.—This invention relates to an improved stand for supporting photographic cameras. It is simple in construction and quite inexpensive, and consists principally of an arrangement of inclined planes, by which the height of the stand and also the inclination of the camera are adjusted, in order to accommodate this to the position of the object to be operated on. By means of this device these operations of raising, lowering and otherwise adjusting the camera are very easily and rapidly performed.

BOOT AND SHOE LASTING MACHINE.—K. Gressau, Virginia City, Nev.—This is an improved machine for lasting or fitting the upper leather of boots and shoes, and consists of an arm or bar, the end of which is firmly fastened to the last through the in-sole which is in its place. This arm has attached to it a series of clamps, which hold the edge of the upper leather, while they are themselves acted upon by screws, which draw the leather tightly across the last and hold it while being stitched. Boot and shoe-makers will find this device very convenient.

◆

Silver in Limestone.

J. P. Kimball has lately written a very interesting article on the silver mines of Santa Eulalia, Chihuahua, Mexico. These mines, said to have been discovered in 1591, are known to have produced more than a million of dollars yearly for the 86 years preceeding 1791. After that time, on account of Indian hostilities and subsequent political troubles, they were gradually abandoned. The mines are in an uplift of the cretaceous fossiliferous limestone. The deposits are spoken of as unique. We quote from the article in *Silliman's Journal*: "The ores, which are mainly the chloride and sulphides of silver, argentiferous galena and salts of lead, together with (though of rarer occurrence) the chloro-bromid (embolite) and iodid (iodyrite) of silver, are very ferruginous, to which circumstance they owe their friable character, and also, to a considerable degree, the spaces in which they have been deposited. Courses of ore are always marked by ferruginous stains, which, properly considered, are segregations of mineral matter, sometimes following cleavages and joints, and sometimes planes of bedding, and, again, sometimes reticulating solid beds, and in all these modes of occurrence, without order or defined limits. A bed, or a number of beds, of the limestone, in places may be thoroughly webbed with such segregations of so decided a character as to impart a concretionary appearance, or as if limestone breccia were cemented by ferruginous ore. In such places the beds are *not* brecciated, but thus strikingly indicate the energy of disintegrating and segregating action under the decomposition or oxydation of iron salts (probably proto-carbonate) originally contained in the limestone, together with diffused salts of silver. These ferruginous portions always afford good mining ground. As some of them are very extensive, and as their distribution is irregular, their excavation results in large and rambling chambers, generally ranging through a number of heavy beds of limestone. Such chambers are often continuous with natural caverns, together forming underground spaces scarcely less imposing than the most noted caves that excite the wonder of tourists."

San Pascual Plantation.

The above is the title of another agricultural organization, which has been recently incorporated, for the purpose of engaging in the cultivation of semi-tropical fruits and other productions in the lower portion of the State. In addition to actual operations in the field, the company will also engage in the business of purchasing, selling, leasing or renting land and its appurtenances for the cultivation named.

The abundant resources of the central and southern counties of the State is attracting the attention and challenging the admiration of the world. The extraordinary advantages of the soil and climate, and their peculiar adaptation to tropical and semi-tropical fruits is already being availed of. Among other means for attracting capital in this direction, and for its immediate and practical application, is the formation of companies, like the above, which will take the initiative, and furnish working capital and employment for the industrious immigrant or resident who may thereby turn his able and willing labor to profitable account. The area of ground in the portion of the State referred to susceptible of cultivation but still untilled is immense, fully equal in extent to the entire area of the State of Massachusetts. The climate of this region is not surpassed for salubrity by any portion of the world, and the desultory experiments in the cultivation of the soil there, and the small amount of labor required, have demonstrated its capacity for the particular class of culture alluded to. The grape flourishes there in its greatest luxuriance, and free from disease; while the orange, lemon, citron, fig, walnut, olive, almond, filbert, etc., and all the cereals, thrive most astonishingly. It is in view of these facts that the company named have turned their attention in that direction, and have secured a large tract of most valuable land, shares in which are offered to the public at a price reasonably low, and in quantities to suit, at $50 each—whole number, 4,000. The managers are gentlemen well known in this community. Their names are: *President*, J. Archibald; *Vice President*, R. M. Widney; *Directors:* J. Archibald, Nath. Heath, R. M. Widney, Chas. J. King and J. A. Eaton; *Treasurer*, London and San Francisco Bank. Office of the Company, No. 344 Montgomery street,—where the Secretary is prepared to give full information with regard to the plan and profits of the enterprise.

◆

The Overland Monthly for May comes fresh and vigorous to us this week and shows no signs of diminished power, but, on the contrary, is rather an improvement on some of the preceding numbers. Its opening article on Rufus A. Lockwood strikes us as an extraordinarily good as well as a most interesting biography of a most dramatic character, and in "Old Bob" and "A Piny-Woods Character" we have sketches by a hand which knows how to delineate the peculiar points of certain phases of life. The "stories" are rather sensational, but good, and "A Lady in Camp" will undoubtedly please the gentler sex. The three articles relating to California will be read with interest and profit, and especially that on silk culture in our State. This is one of the articles which attract so much attention from abroad to our resources. The admirers of "Shoo-Fly" have the opportunity of seeing a paraphrase of the popular song (?) in the Latin tongue, and there is an abundance of good matter on every page of the magazine. Those connected with mining matters, we must not forget to state, will find, under the heading of "In and Under Guanajuato" a most readable sketch of the working of a Mexican mine, and the toils and sufferings of the miners, whose labors are often interrupted for more martial ones when a revolution is gotten up by some "ambitious scoundrel."

The Sutro Tunnel.

We have previously noticed the fact that Mr. Sutro had, after a gallant fight, defeated the bill presented in Congress for the release of the Comstock companies from the payment of a royalty of $2 per ton on all ore extracted from the mines, after the tunnel was within five hundred feet of the west wall of the vein.

That this royalty may prove a heavy burden in case that, at some future time, it may be possible to work very low grade ores, seems to us very probable. It is by no means impossible that we may be able to work with advantage ores worth a few dollars per ton, in which case the royalty of $2 will be a very heavy tax. Still this is not yet the case, and, if successful, the tunnel will certainly aid in legitimate operations. Besides, we do not see how the contract already made can be broken. We find the following very apt remarks in the *N. Y. Engineering and Mining Journal:*

The bill, though actively supported by the senators and representatives from California and Nevada, was defeated by an overwhelming vote. We think the house decided rightly. The legal complications of the matter do not concern us. We base our opinion, and we think the House based its action, on the conviction that the Sutro tunnel is a necessary and important work. Either the companies wish to run it themselves, after putting Mr. Sutro out of the way, or they do not wish to have it run at all. In the former case, there is no reason why the original proposer and promoter of the plan should be set aside in favor of a heterogeneous combination of shifting proprietorship, always at odds with each other, and almost certain not to carry out the work. When the thirty or forty companies on the Comstock lode can point to any one scheme which they have ever harmoniously executed for the benefit of all, it will be perhaps less preposterous to intrust them with this great work. As we have often said, the companies ought to have run this tunnel long ago. They have wasted on superficial tunnels, not one of which is now used, more money than this would have cost; they have thrown away an equal amount in litigation; and the reason is, that they have been operated in the interest of temporary owners, of immediate profits, and of stock speculations.

But their present cry is, that the tunnel is quite unnecessary, because they are working out old reserves of low grade ore near the surface, and do not need deep drainage, ventilation, transportation, etc. This is a confession of the plan formed two years ago, to build a railroad for cheap transportation, and then gut the mines of what ore is available, suspending explorations in depth, and abandoning the ground when the present reserves are worked out. It is a plan which ruins the mines, but may enrich the present owners. We have only to say of it, that it demonstrates the necessity of just such a law as that of which the companies now complain. They shall be forced by the Government, which still owns every foot of the Comstock, to allow others to go forward with the explorations which they propose to neglect.

The question is not one of government aid in money to the tunnel; it is merely, whether the ancient and approved custom of a tunnel-royalty should be allowed in this case, as an encouragement to a measure which promises to explore this important vein in depth.

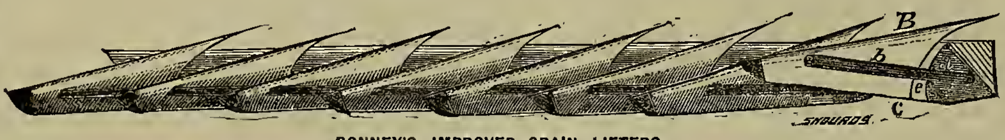
It is true that a few shafts on the vein are very deep, and that comparatively little additional water has been met in them; but increasing depth, and the consequently increasing expense both of pumping and hoisting, present difficulties enough, without any increase of water. As for ventilation, it is well known that the use of the Root blower has become indispensable in the deep mines; and it has been asserted that the artificial ventilation so produced has dried the timbers underground, so as to make them very combustible. The awful fire in the Crown Point, Kentuck and Yellow Jacket, is an illustration of this kind of danger, which, we suggest, does not need to be repeated. In case of a fire occuring in a mine provided with a deep tunnel for ventilating a draught of air would inevitably be in at the tunnel, and out by the shaft. Consequently, miners escaping in the direction of the tunnel would meet with fresh air, and a safe exit. In the catastrophe of last year, the unfortunate victims were cut off from escape by the fire itself, suffocated first, and burned afterwards.

Messrs. Sargent and Fitch made strong argument on the legal aspects of the case; and in that particular, we do not attempt to judge between them and the majority of the House; but they are not on tenable ground when they condemn the plan of a deep tunnel to the Comstock lode; and we think they lost their sturdily maintained battle, simply because they assailed not only the law, but the thing itself, whereas the House considers it of national and immediate importance. Those about to leave a sinking ship may not care to see her saved; but the people do not yet give up the ship.

◆

Bonney's Improved Grain Lifters.

In cutting grain it is often necessary to have some apparatus to elevate the heads which may have been thrown down by the wind or rain. The important question is to get that device which is the most efficient for the purpose, and at the same time the cheapest. The patentee of the lifter which we illustrate claims that he has solved this question. The lifter is compact and strong and easily attached or removed by simply drawing the back bolt. They are, moreover, adjustable, as shown in the sketch, B being raised or depressed by changing the stop bolt, *e*, in front of the shank, *a*, allowing the header to cut close to the ground and dispensing with the extra cost of buying what are termed "trinklers."



BONNEY'S IMPROVED GRAIN LIFTERS.

This is a California invention, which will prove of great use in our State, where there is a broad field for such agricultural devices. Farmers would do well to examine this lifter, which is manufactured by the patentee, O. Bonney, Jr., corner Mission and Beale streets, S. F. Parties desiring information with regard to county and State rights can obtain the same by applying to Wiester & Co., Patent Brokers, 314 Bush street, San Francisco.

◆

The Australian Gum Tree, or Century Plant, at Los Angeles.—An attentive correspondent in Los Angeles county expresses much gratification at our late illustration descriptive of the method of transplanting large trees, and at the same time communicates the following:

There is at Mr. Rose's farm, at Mission San Gabriel, an Australian gum tree—*Eucalyptus amyddalina*—eight years old, whose trunk towers up, like the main mast of a ship, full sixty feet high; and I am told that there are others of a like size at Mr. Wolfskill's.

There is a species of the American aloe, such as in Mexico is called the "Maguay," which is the so-called "century plant," only it blooms here in ten years. It has a beautifully tremstariant, white, long fibre, which the shoemakers of the Mission formerly made use of for sewing shoes, because it was so strong. The fiber, in a full-grown leaf, is more than a yard long, and about as fine as No. 40 cotton. Whether it could be divided to make it finer, so as to make it like the pine-apple cloth, I do not know. The variety we have on our place is not indigenous here, but must have been brought from Mexico. After mashing the leaf, and stripping it in pieces, it is often employed here to fence with. There is a smaller variety growing wild among the mountains. I should think it might be made a useful textile, especially in this dry climate, as it grows without water. There are some plants at Ross Browne's, in Oakland, of the larger sort.

◆

Insurance.—M. Mooney will deliver a lecture at Platt's Hall, on Monday evening next, on the subject of Insurance.

Gold Fields of Victoria.—No. 5.

Three-Dollar Quartz Profitable.

The author of "Gold Fields of Victoria," 1862, publishes statistics to show that a number of companies were working quartz in the Ballarat District, which produced less than $3 per ton, yet afforded a profit of about 30 per cent. per annum upon the capital employed. They are enabled to do so from the fact that they work the entire hill, or nearly so, crushing everything, "quartz, "mullocks," "casing," etc.

The Black Hill Company's mill of sixty stamps of 782 pounds each, and with an engine of 100-horse power, consume 150 tons of wood a week, crush from 1,000 to 1,500 tons of "stuff," and employ ninety men and four horses. They use a self-feeding apparatus, which requires but one man for the sixty stamps. The consumption of iron was one ton a week. The "stuff" averaged 2 dwts. 18 grs.=$2.27 per ton. The cost of mining was 4s.=$1; of crushing, 2s. 10d.=70 cents. The dividends paid amounted to 30 per cent.

Statistics.

In 1858 the population was 77,345. The number of acres under cultivation was 57,472. The imports amounted to $5,282,185, and the exports to $6,014,545, and the gross revenue was $1,962,275. In 1867 the population had increased to 659,887, the imports to $58,370,400, and the exports to $63,622,135. There were under cultivation 631,207 acres, the estimated gross revenue was $16,052,520, and the expenditure amounted to $16,842,680. Vide "The Mineral Districts and Gold Fields of Victoria," by R. B. Smythe:

"From various causes the number of mines has been reduced from year to year, and it is a matter for surprise that the yield of gold has not diminished in proportion. Now that the industry has assumed a settled character; that capital is available, and larger enterprises undertaken with confidence; and good wages are to be got everywhere by industrious and skillful men, it is probable that we shall soon see some change for the better in the numbers employed." It is Mr. Smythe's opinion that the gold mines now need a fresh supply of young and able men! Our readers can apply these statistics and facts for themselves.

◆

Narrow Gauge Railroads.—A paper on this subject was lately read before the London Association of Engineers by a Mr. Burrell, who advocated a narrow gauge—say from two feet to three and a half feet. He asserted that lines could be constructed even in broken and mountainous countries with the narrow gauge at from one-third to one-half of the cost of those with the standard gauge (four feet eight and a half inches). Such lines had been constructed successfully in Norway, Canada, Queensland, Peru, and on the continent to the extent of several hundreds of miles. He described a short road now being constructed in Spain which has gradients from one in twenty to one in forty and curves of less than four chains radius.

◆

The Stone of the Pyramids.—Pouchet says the Pyramids are built of the rock of the Arabian chain, which extends along the Nile. This rock is formed of agglomerated fossil shells, known as *nummulites* (Latin *nummulus*, a small coin), from their resemblance to pieces of money. The Sphinx is cut from a different rock, composed of a smaller species of nummulite.

◆

Electricity and Capillary Attraction.—The rise of sap in trees and plants has been explained on the principle of capillary attraction, but M. Becquerel considers that electricity is an acting cause. A capillary tube that will not allow water to pass through it, does so at once on being electrified, and he considers that electro-capillarity is the efficient cause of sap traveling in vegetable life.

◆

Portable Laughing Gas.—Dr. Doremus, of New York, has put protoxide of nitrogen into portable shape for dentists' use. He condenses it into the liquid state, which is done by a pressure of 800 pounds to the square inch, and bottles it up in a stout jar.

POWDER,

Of SUPERIOR QUALITY, FRESH FROM THE MILLS. It being constantly received and transported into the interior, is delivered to the consumer within a few days of the time of its manufacture, and is in every way superior to any other Powder in Market.
We have been awarded successively

Three Gold Medals

By the MECHANICS' INSTITUTE and the STATE AGRICULTURAL SOCIETY for the superiority of our products over all others.
We also call attention to our

HERCULES POWDER,

Which combines all the force of other strong explosives now in use, and the lifting force of the best blasting powder, thus making it vastly superior to any other compound now in use.
A circular containing a full description of this Powder can be obtained on application to our Office.

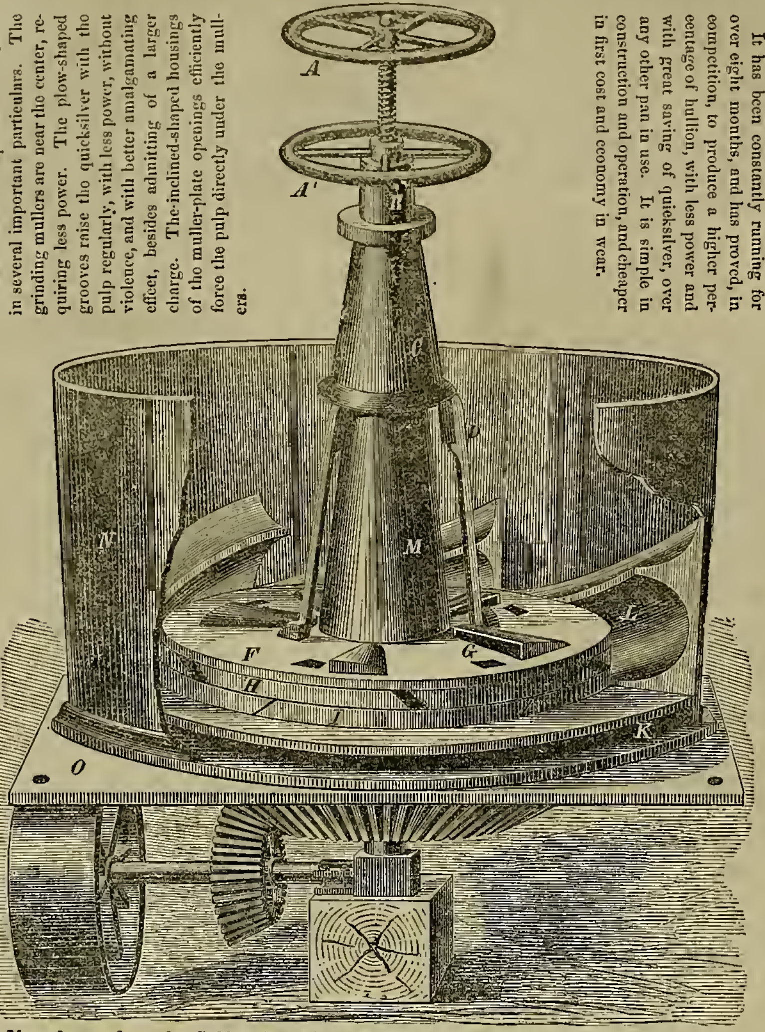
STEVENSON'S PATENT MOULD BOARD AMALGAMATING PAN.

This Pan is far superior to all others in several important particulars. The grinding mullers are near the center, requiring less power. The plow-shaped grooves raise the quicksilver with the pulp regularly, with less power, without violence, and with better amalgamating effect, besides admitting of a larger charge. The inclined-shaped housings of the muller-plate openings efficiently force the pulp directly under the mullers.

It has been constantly running for over eight months, and has proved, in competition, to produce a higher percentage of bullion, with less power and with great saving of quicksilver, over any other pan in use. It is simple in construction and operation, and cheaper in first cost and economy in wear.



Manufactured at the Golden State Iron Works (Co-operative), 19 First street, S. F.,

Where it can be examined and further particulars be learned; or persons may apply to the inventor and patentee, Mr. C. C. STEVENSON, at the Douglas Mine, Gold Hill, State of Nevada, where the Pans have long been in constant operation. 15v20-1mr,1amtf

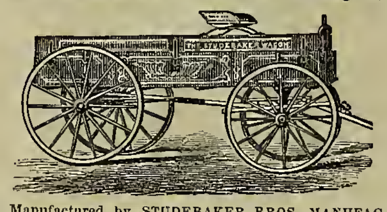
The Celebrated Studebaker Wagon,



Manufactured by STUDEBAKER BROS. MANUFACTURING CO., South Bend, Indiana. WAGON DEALERS, there are nine reasons why you should buy the above Wagon:

First.—They are made of the best selected INDIANA TIMBER, thoroughly seasoned under cover.

Second.—They are made by experienced mechanics.

Third.—The lightest running and most durable Wagon in the market.

Fourth.—Their Thimble Skeins never break, while all others do.

Fifth.—Most uniform and best proportioned Wagon in the market; any part of one will fit another, while other makes will not.

Sixth.—The only Wagon in which the Slope Shoulder Spoke is used; hence they have the best Wheel, which is actually the foundation of the Wagon, and should be carefully examined by persons buying.

Seventh.—They are sold only by responsible parties, and every Wagon is warranted to give entire satisfaction.

Eighth.—Because Teamsters will tell you they are the best Wagons, for all purposes, on the road.

Ninth.—Last, but not least, Studebaker Brothers are practical men, attend to their business personally, and do not entrust it entirely to foremen, as is generally the case in large factories; hence the superiority of their work over all others. Sold by

DR. ABORN,

Oculist, Aurist,
AND
CATARRH, THROAT
AND
Lung Physician.

No. 22 KEARNY STREET,
SAN FRANCISCO, CAL.

Testimonials from Well-known Citizens of California as evidence of his success.

Card from Charles N. Fox, Esq., of the firm of Campbell, Fox & Campbell, Attorneys, 528 California Street.

I have for many months suffered from Catarrh, accompanied with unpleasant sensations and sounds in the ears. Recently I found my hearing impaired, and at once applied to Dr. Aborn, No. 22 Kearny street, San Francisco. He improved my hearing almost instantaneously, and now, after being under his care six days only, I feel as if entirely cured, and my hearing is restored. CHARLES N. FOX.
San Francisco (Cal.), Jan, 10, 1870.

Card from S. O. Houghton, Esq., Attorney at Law.

I have been afflicted with severe nasal Catarrh for two years, which a few months since extended to my throat, producing a distressing cough, and seriously impairing my health generally. I have been under treatment by Dr. Aborn, at 22 Kearny street. San Francisco, for about three weeks, and have been already greatly relieved—my cough has almost disappeared and my health greatly improved. By one application, Dr. Aborn relieved me of a very severe neuralgic pain, and with four applications it was entirely cured. S. O. HOUGHTON.
San Jose (Cal.), Nov. 22, 1869.

From Hon. Jas. A. Johnson, M. C., California.

To whom it may Concern.—Having been a sufferer with Catarrh and a severe bronchial affection for more than seven years, and having found great relief by submitting myself to Dr. Aborn's treatment for a few days only, I take pleasure in saying Dr. Aborn, with his new and improved instruments for local applications to the lungs, air passages, eyes and ears, should encourage all who are affected in those parts to cherish a lively hope that they may find quick and permanent relief. Very truly, JAMES A. JOHNSON, M. C., California.

A Wonderful Cure.

Having been afflicted for over twenty years with a disease in the left nostril, which has been called by different names—cancer, scrofula and ozena—different physicians have tried their skill in attempting its cure, but without success. It has rendered me incapable of labor for the last two years. Since the beginning of June last I have been in the Sacramento hospital reduced to a mere skeleton. On the 23d of November I left the hospital, and since the 26th have been under the treatment of Dr. Aborn in this city, and the disease is already nearly cured, and my strength and general health very much improved, and I have full confidence of a perfect cure. Already I have gained many pounds in weight, and look and feel like another person. The success of Dr. Aborn's treatment in my case should be sufficient to encourage all who have chronic diseases to make another trial for that good prize—health.

WILLIAM BEARDSLEE.
Pacific House, San Francisco, Dec. 13, 1869.

Another Remarkable Cure.

For the benefit of the afflicted and as an act of justice to the skill of Dr. Aborn, I make the following statement: For about two years I was seriously afflicted with a bronchial affection. I had a distressing cough, difficulty of breathing, expectoration, night sweats, and was losing flesh very rapidly. I was treated by five physicians without any benefit, but continued to grow worse, and was finally advised by them to leave the city, as in their opinions I could not be cured in this climate; but my business relations were such as to preclude a change of climate, although my health was declining so fast that I could not have lived long without relief. Two months ago, when Dr. Aborn arrived, I read his publications and the testimonials of his remarkable cures, which led me to believe that there must be merit in his treatment. So I placed myself under his care, and it is with great pleasure that I am able to say that he has cured me of those distressing and dangerous bronchial affections; also, the night sweats, cough, etc. I was unable to attend to business since April last, until after being under Dr. Aborn's treatment for one week. My improvement was so rapid that in one week's time I was able to resume my business, and I have continued to gain ever since so rapidly that even my friends are surprised at the remarkable results of his treatment.

VINCENT MONATTI,

Report of Samuel S. Fisher, Commissioner of Patents.—1869.

[CONTINUED FROM PAGE 206.]

Assistant Commissioner.

The duties devolving upon the Commissioner of Patents cannot be performed by one person. He is not only the executive head of a large bureau, but he is invested with the sole right to extend patents, and he is charged with the duty of hearing appeals from the board of examiners-in-chief. The extension cases amounted to 153 during the last year, and as more patents were granted in 1856 than in 1855, the number of applications must constantly increase. The appeal cases of all classes amount to about 200 per annum, some of them involving the consideration of vast amounts of testimony and voluminous arguments. When to this is added so much of the correspondence as he must attend to in person, applications for office, and the necessary time for interviews, it is obvious that the labors must be arduous and unremitting.

I therefore respectfully recommend that an assistant commissioner be provided for by law, to be appointed by the President, by and with the advice and consent of the Senate; such officer to perform the duties of Commissioner in the case of death, sickness, or absence; and such other duties as may be assigned to him by the Commissioner.

Room over South Portico.

My attention was lately called to the existence of a room over the south portico of the Patent Office building, which, when explored, proved to be a hall 90 feet long by 30 feet in width and 20 feet in height. This has been hitherto practically inaccessible, as it was unfinished and useless. It has now been fitted up and rendered easy of access at a moderate expenditure, thus affording very eligible quarters for the library of copyrights and for the copyists of drawings.

Smaller rooms exist over the other porticoes of the building, which may be profitably arranged for the reception of rejected models.

Copyrights.

Congress omitted at its last session to make any appropriation for the care of the copyrighted books and records.

I am persuaded that the time has come when a radical change should be made in the system of registering copyrights. This is now done in the clerks' office of the various district courts. It is so imperfectly done that coyrights are proverbially worthless. They are usually invalid from a failure to comply with essential formalities; because no officer is interested to see that these formalities are complied with. The clerks omit in many cases to send their records to this office, and to transmit the books. Many of the latter are never received at all. Meanwhile Congress has been called upon from year to year to make appropriations from the funds in the treasury for the care of these books and papers. It is submitted, since mail facilities are now so cheap and abundant, that the work of registration could be done much more thoroughly in the Patent Office, and that the fees for that service (about $3,500 per annum) would pay all the expenses of the necessary clerical force, and for the custody of the books. If it were the business of a division in this office to do this work, correspondence could be maintained with authors and publishers, and copyrights could be perfected. I also ask that the Patent Office be permitted to display and use as books of reference, under proper restrictions, the books, especially those of a legal, mechanical, and scientific character, which are deposited by the authors and publishers under the law. These have been hitherto of no value whatever, except as vouchers.

Trade-marks.

By conventions between the United States and France and Russia (U. S. Statutes at Large, vol. XV, P.—) provision is made for the deposit of trade-marks by citizens of either country in the United States Patent Office, the Tribunal of Commerce of the Seine, at Paris, and the Department of Manufacturers and Inland Commerce, at St. Petersburg. No fee is provided for the reception and filing of these papers. As the office labor to be performed in relation to them is analogous to that attending the filing of caveats or disclaimers, the same fee ($10) would be a proper charge.

It would also, doubtless, be a proper provision if a law were enacted giving validity to trade-marks so filed, either for an indefinite or for a limited period of time.

Conclusion.

In conclusion, it is right that I should say that no class of our citizens has done more for the glory and substantial prosperity of the nation than the mechanics and inventors of the United States, and yet they have never been favored children.

They do not deem it too much to ask that the Patent Office, which is the only institution which they can specially call their own, and which they have built up with their money and established by their genius, shall be supplied upon a liberal scale with every needed appliance for the performance, in the best manner, of all its legitimate duties.

Respectfully submitted.

Samuel S. Fisher,
Commissioner.

◆

Shoshone Falls, Idaho.

We clip the following from the Owyhee *Avalanche* of March 19th: "These falls rival in magnitude and grandeur those of Niagara and Yosemite. Snake river there runs through a narrow, rocky gorge, terminating abruptly in precipitous cliffs fully one thousand feet above the rapids, which form a series of cascades from thirty to sixty feet in height, and finally calm themselves into one smooth expanse which trembles, as it were, on the verge and then leaps in one unbroken mass 210 feet into the yawning chasm below. The contour of the falls is something like a horse-shoe, and their width, following the line of water, is said to be at least four hundred yards. Below the falls the river is perfectly calm and smooth, giving no evidence of the fearful leap just taken. There is no timber in that vicinity except some stunted junipers that find support in the crevices of the rocks. Altogether the sublimity and grandeur of the scenery cannot be surpassed. The solitude of the spot, the deafening roar of the falling waters and the dark outline of the huge black rocks rising above the mist, all produce a sensation of awe on the mind of the spectator and leave an impression of the wonders and immensity of creation."

◆

Asphaltum Pipe.

In our article on this subject in the issue of April 16th, when speaking of the price, the word *inch* was used instead of *foot*. The prices charged are as follows:

2-in. pipe, 10 cts. per in. diam. or 20 cts. per running ft.
4 in. pipe, 10 cts. per in. diam. or 40 cts per running ft.
6-in pipe, 10 cts. per in. diam. or 60 cts. per running ft.

And upwards in the same proportion.

◆

A Traveling Bog.—The shifting of a bog is reported from Ballylongford, County Kerr. The bog, which covered over 200 acres, moved to a distance of nearly half a mile inland, creating great consternation in the neighborhood. Several cabins were thrown down, and cattle and horses were lost. A lake took the place of the bog. The inhabitants on the skirts of the morass barely escaped, the motion of the bog being sudden and unexpected. This not uncommon occurrence may have happened in the ancient coal era, and given rise to some of the appearances (faults) which puzzle us most, in studying the coal.—*U. S. R. & M. Register*.

Treatment of Rebellious Silver Ores, by Charles H. Aaron—a pamphlet of eight pages of concise reading, of practical value to parties interested in the subject. Printed and sold by Dewey & Co., at this office, for 25 cents, post paid.

Philo B. Fox is requested to report list of subscribers taken for the Scientific Press to date. His agency (for Napa, Sonoma and Mendocino counties) is hereby revoked. His receipts, given previous to this notice, will be acknowledged at this office.

DEWEY & CO., Publishers.
San Francisco, April 28, 1870.

Important Invention.—The best drink, not containing alcoholic stimulants, yet answering all the requirements, is that made by Kenyon, Gass & Co., and known as Champagne Mead. It is recommended by the medical fraternity of this city, and should be the exclusive drink of all temperance men. It contains no injurious acids. *

C. Muller, optician, 205 Montgomery, stands first in his profession, and all those who suffer from defective eye-sight should apply to him. *

Continental Life Insurance Co., 302 Montgomery street, corner of Pine.

Mason's Bread of Life, for Dyspeptics, Coughs, Colds, Asthma, Catarrh, Hoarseness, Bronchitis and Sore Throat. Price, 25 cents per box. These lozenges are free from all dangerous properties. Compounded and put up by Dr. J. H. Mason, 750 Howard st. 16v20-3m

No family should be without the Portable Gas Light. It costs only one-fourth as much as coal gas, less than coal oil, and the light is equal to the best coal gas. Call on P. J. Philips & Co., No. 650 Market street, and see it. County rights for sale. It is perfectly safe and reliable, and much more convenient than any other light in use.*

A Valuable Book for Inventors and Artisans.—Dewey & Co., publishers of the Scientific Press and Patent Agents, have just issued a neat little volume of over five hundred well executed cuts of the principal mechanical movements known. These useful representations of the various appliances of power are printed side by side with explanatory notes, which makes the subject clear to every reader. Such a book should be in the hands of every mechanic, and form part of every public school library. It is a handy book, and cheap enough for every farm, shop and factory. Sent to any address from the Scientific Press office, postpaid, for $1.—*New Age.*

Extract from a letter dated St. Louis, Mo., March 1, 1870: "Messrs. Dewey & Co.:—The Scientific Press has been received. Though I am a constant reader of the Scientific American and great admirer of it, I confess my surprise on discovering the Pacific slope in possession of its equal in every respect. A. J. K." (inventor).

Business Fortunes are often made easily, quickly and legitimately by Patent Rights. We advise both sellers and purchasers to patronize reliable agents only. Weister & Co., patent brokers, No. 314 Bush street, San Francisco, are one of the most honest, reliable firms in the United States. *

Photography.—For Cabinet Photographs, or Enameled Cards, of the very best quality, you must go to the NEW YORK GALLERY, Nos. 25 and 27 Third street, San Francisco. Every picture warranted to give satisfaction.

Greatest Discovery Ever Made.

MR. J. W. MAC, while a resident in New Zealand, was so afflicted with the RHEUMATISM, that for years he was completely crippled and unable to attend to business. The symptoms were of the worst type—knees painful and swollen, with sinews contracted; shoulder, arm and hand rendered useless, and accompanied with continued excruciating pain. While in this state of suffering, he got acquainted with a native of the country, who applied to the parts affected a composition spread on coarse canvas, the properties of which were so wonderful that in a short time all the pain left him, the swelling disappeared, his sinews relieved, and he was able to resume his usual avocations. So effectual has been the remedy, that to this day he has enjoyed perfect health, without the slightest return of his former complaint. Knowing the great blessing such a remedy would be to those afflicted with this painful disease, he with great difficulty and expense obtained the secret of preparing the Plaster; and during the many years MR. MAC has applied these Plasters in New Zealand, Tasmania, New South Wales, and this city, their effect has been marvelous, giving to the most painful and long-standing cases sure and certain relief. The most incredulous will be convinced by referring to these persons: B. W. Owens, 405 Front street; F. B. Alderson, Traveling Agent for Dewey & Co., 414 Clay street; James Flynn, 519 Mission street; Michael Gorman, No. 6 Front street; Mrs. W. S. Wright—late of Gilmore House—518 Folsom street, now agent at Virginia City; E. Shenley, corner Montgomery and Filbert streets; W. M. McLeod, Depository American Tract Society, 657 Market street, and a host of others, who all bear testimony to the unparalleled healing powers of J. W. MAC'S (rightly termed Magic) Plasters, for the cure of Rheumatism, Gout, Weak Loins, Tender Feet and Neuralgia. J. W. MAC may be consulted at his office, rooms Nos. 34, 35 and 36, 128 Kearny street, San Francisco, between the hours of 9 to 12 a. m., 2 to 4 p. m. and 7 to 9 p. m.

MARAVILLA COCOA.—*For Breakfast.*—The *Globe* says: "Various importers and manufacturers have attempted to attain a reputation for their prepared Cocoas, but we doubt whether any thorough success has been achieved until Messrs. Taylor Brothers discovered the extraordinary qualities of 'Maravilla' Cocoa. Adapting their perfect system of preparation to this finest of all species of the Theobroma they have produced an article which supersedes every other Cocoa in the market. Entire solubility, a delicate aroma, and a rare concentration of the purest elements of nutrition, distinguish the Maravilla Cocoa above all others. For homœpaths and invalids we could not recommend a more agreeable or valuable beverage." USE

DR. S. GIRARD SMITH'S

ARAMIRACULAS

— FOR —

RHEUMATISM, GOUT AND NEURALGIA

CURES GUARANTEED.

Has cured Thousands. Has never been known
One bottle will relieve you.

OFFICE, No. 621 KEARNY STREET.

Agents Wanted in every City and Town.—Terms Liberal.

Dr. S. Girard Smith, 621 *Kearny street.*—Dear Sir It would be hard for me to say how much I thank you for the benefit your ARAMIRACULAS has conferred on me in curing my RHEUMATISM. I was confined to my bed when I first commenced to take your medicine, and after using ONE BOTTLE I am now able to work as well as before. If you know anything about having that afflictive complaint, you must know how good it is to be cured. I will state to those who may not believe in your medicine, that they can be convinced by referring them to me. Very respectfully, yours,

ENON HARRIS,
Everard's Auction Rooms, 527 Kearny street.

Statement of an old and well-known Physician who has practiced extensively in Europe and America.

We must admit that the many systems of medicine by which we have attempted to heal the human body, and rid it of disease, from the science of ALLOPATHY down to HYDROPATHY, how little they have succeeded, time has abundantly shown by their number of failures. In the cure of RHEUMATISM, GOUT and NEURALGIA, Dr. S. Girard Smith has laid aside the old way and adopted a system, so simple, that I must admit, is so natural and direct, that it recommends itself to all who are suffering with the above diseases. And it challenges and defies all the old methods of treatment. Although I have been educated through a regular course, and graduated in Europe, I must acknowledge the right, and also give due credit for personal benefit received by the new system as practiced by DR. S. GIRARD SMITH, which induces me to bear this testimony to its merits, for the benefit of suffering humanity.

A. M. HOFFMAN, M. D.,
11v20-3m New Orleans.

Ayer's
Hair Vigor,

For restoring Gray Hair to its natural Vitality and Color.

A dressing which is at once agreeable, healthy, and effectual for preserving the hair. *Faded or gray hair is soon restored to its original color with the gloss and freshness of youth.* Thin hair is thickened, falling hair checked, and baldness often, though not always, cured by its use. Nothing can restore the hair where the follicles are destroyed, or the glands atrophied and decayed. But such as remain can be saved for usefulness by this application. Instead of fouling the hair with a pasty sediment, it will keep it clean and vigorous. Its occasional use will prevent the hair from turning gray or falling off, and consequently prevent baldness. Free from those deleterious substances which make some preparations dangerous and injurious to the hair, the Vigor can only benefit but not harm it. If wanted merely for a

HAIR DRESSING,

nothing else can be found so desirable. Containing neither oil nor dye, it does not soil white cambric, and yet lasts long on the hair, giving it a rich glossy lustre and a grateful perfume.

Prepared by Dr. J. C. Ayer & Co.,

Practical and Analytical Chemists,

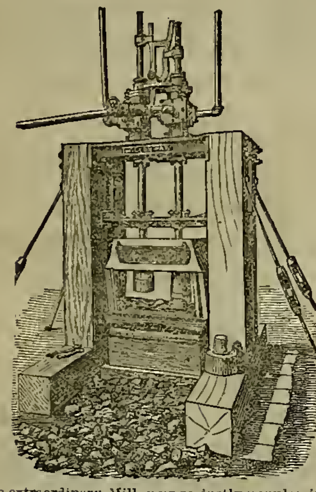
Machinery.

THE WILSON
Patent Steam Stamp Mill.



This extraordinary Mill, now so justly popular in the East, is now offered to the miners of the Pacific Coast. Having been in operation now for about eighteen months, the Company feel confident that the

WILSON STEAM STAMP MILL,
For Durability, Efficiency,
AND ECONOMY OF WORKING,
HAS NO EQUAL.

The Wilson Steam Stamp Mill is the only Steam Mill that has had the severe ordeal of practical working, and proved itself eminently successful. It is now in operation in several of the Eastern States and Territories, and gaining an envious popularity. The whole machine is so simple as to be readily understood by the most ordinary minds. In fact, its simplicity is its durability. The expense of crushing rock or cement with this Mill is less than one-half the expense of any other Stamp Mill, and less than one-half the cost. For further particulars inquire of

A. BICKNELL, Agent,
Nevada City, California,

Or of THE WILSON STEAM STAMP MILL CO., 326 Walnut street, Philadelphia, Pa.

NOTICE.—All persons are hereby warned not to manufacture or use any Steam Stamp Mills that are an infringement on the Wilson Patents, as they will be prosecuted to the utmost rigor of the law.

F. R. WILSON,
20v19-tf Supt. W. P. S. S. M. Co., Philadelphia.

VARNEY'S
PATENT AMALGAMATOR.

These Machines Stand Unrivaled.

For rapidly pulverizing and amalgamating ores, they have no equal. No effort has been, or will be, spared to have them constructed in the most perfect manner, and of the great number now in operation, not one has ever required repairs. The constant and increasing demand for them is sufficient evidence of their merits.

They are constructed so as to apply steam directly into the pulp, or with steam bottoms, as desired.

This Amalgamator Operates as Follows:

The pan being filled, the motion of the muller forces the pulp to the center, where it is drawn down through the aperture and between the grinding surfaces. Thence it is thrown to the periphery into the quicksilver. The curved plates again draw it to the center, where it passes down, and to the circumference as before. Thus it is constantly passing in a regular flow between the grinding surfaces and into the quicksilver, until the ore is reduced to an impalpable powder, and the metal amalgamated.

Setlers made on the same principle excel all others.—They bring the pulp so constantly and perfectly in contact with quicksilver, that the particles are rapidly and completely absorbed.

Mill men are invited to examine these pans and setlers for hemselves, at the office, 229 Fremont street,
1v1 San Francisco.

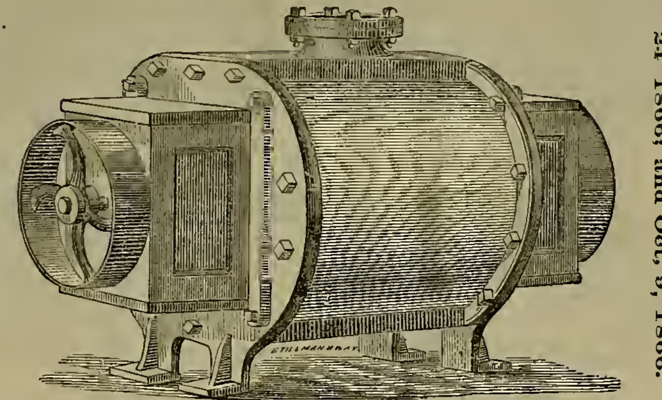
Crandall's Patent Spring Bed.

Manufactory, corner Front and M streets, SACRAMENTO. COOLEY, HENRY & CO., Proprietors. These Spring Beds, wherever known, are universally acknowledged to be superior to any other in use. They are light, durable and elastic, and present no harborage for bugs or any other kind of vermin, thus being free from the objections so often urged against the ordinary spring beds. ☞ Orders received at our manufactory, or at our agency in San Francisco. 7v20-3m

---

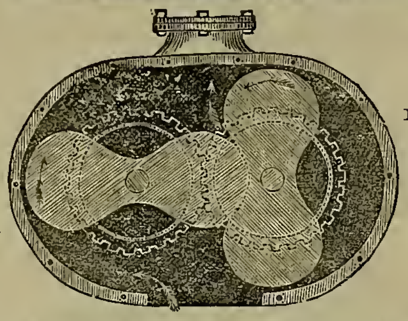
ROOT'S PATENT FORCE BLAST ROTARY BLOWER.
MANUFACTURED BY KEEP & BARGION,
At the Globe Iron Works, Stockton, California.

Awarded the First Premium at the Paris Exposition.



Patented Nov. 1st, 1864; July 24 1866; and Oct. 9, 1866.

ADAPTED FOR **Smelting, Foundry, Mining and Steamships.**



REQUIRES **Fifty Per Cent.** LESS POWER **Than any Blower** Now in use.

One of these Blowers may be seen on exhibition at W. T. Garratt's Brass Foundry, corner of Mission and Fremont streets. They are also in use at the Almaden Quicksilver Mine; Gridley's Foundry, Gold Hill, Nevada; Ætna Iron Works, San Francisco, and many other places.

CAUTION.—Purchasers will find it to their advantage to apply direct to the Stockton Agency, as certain parties, not authorized to manufacture the Blower, have put in the market machines of inferior construction, which do not answer all the requirements of the genuine article.

Quartz, Saw and Grist Mill Irons, Steam Engines, Horse Powers, High and Low Pressure Steam Engines, Steamboats and Propellers, made at short notice.

For circulars and further information, address

PAUL'S
DRY AMALGAMATING
Electric Process.

A SYSTEM FREE OF DUST, that will cheaply work Gold Ores, and gather flour gold, with the same readiness as the coarser, whether free or associated with iron, copper, lead, antimony, or zinc, or all together in one matrix, and produce bullion free of any or all of the base metals

That will work Silver Ores carrying any of the base metals to a higher percentage than any system of raw amalgamation, and produce bullion not less than .950 fine.

That where silver is associated with a large percentsge of lead, copper, zinc, or antimony, a certain percentage can be extracted in fine bullion—the percentage owing to ore—say 30 to 60 per cent, The residue in base metals can be taken up for smelting or roasting by concentration, at no additional expense; the bullion and concentration equaling 95 per cent. of value of ore.

[From Superintendent of Rosecrans S. M. Co.]

This is to certify, that I had worked at the Haskin & Grove Mill, Empire, 1,600 pounds of gold ore by Paul's Dry Amalgamating Process, as a test against my own working of same ore by the stamp mill, working wet, and that on comparing results the yield by the Paul Process exceeded the mill returns sixty-three per cent. per ton.

I am satisfied the Paul Process will gather the fine gold, and which it is not possible for a wet working mill to collect. AUG. GUIBOR.

☞ Pamphlets setting forth the practical working of the Process will be forwarded on receipt of any address. Parties interested in mining can gain further particulars by applying to

THE GREAT MEDICAL DISCOVERY!
Dr. J. Walker's California
VINEGAR BITTERS.

More than 500,000 Persons

Bear testimony to their wonderful Curative Effects.

WHAT ARE THEY!

They are not a vile

FANCY DRINK,

Made of Poor Rum, Whiskey, Proof Spirits, and Refuse Liquor, doctored, spiced, and sweetened to please the taste, called "Tonics," "Appetizers," "Restorers," etc., that lead the tippler on to drunkenness and ruin, but are a true Medicine, made from the native roots and herbs of California, FREE FROM ALL ALCOHOLIC STIMULANTS. They are the GREAT BLOOD-PURIFIER AND LIFE-GIVING PRINCIPLE, a perfect Renovator and Invigorator of the System, carrying off all poisonous matter, and restoring the blood to a healthy condition. No person can take these Bitters according to directions and remain long unwell.

They are a gentle Purgative as well as a Tonic, possessing, also, the peculiar merit of acting as a powerful agent in relieving Congestion or Inflammation of the Liver, and all the Visceral Organs. In Bilious, Remittent and Intermittent Fevers, these Bitters have no equal. For full directions, read carefully the circular around each bottle, printed in four languages—English, German, French and Spanish.

One Hundred Dollars will be given for an incurable case, provided the bones are not destroyed by mineral poisons or other means, and the vital organs wasted beyond the point of repair.

For Inflammatory and Chronic Rheumatism, and Gout, Dyspepsia or Indigestion, Bilious, Remittent and Intermittent Fevers, Diseases of the Blood, Liver, Kidneys and Bladder, these Bitters have been most successful. Such Diseases are caused by Vitiated Blood, which is generally produced by derangement of the Digestive Organs.

Cleanse the Vitiated Blood whenever you find its impurities bursting through the skin in Pimples, Eruptions or Sores; cleanse it when you find it obstructed and sluggish in the veins; cleanse it when it is foul, and your feelings will tell you when. Keep the Blood pure and the health of the system will follow.

J. WALKER, Proprietor.

FOR FEMALE COMPLAINTS, whether in young or old, married or single, at the dawn of womanhood or the turn of life, these Tonic Bitters display so decided an influence that a marked improvement is soon perceptible in the health of the patient. PIN TAPE, and other WORMS, lurking in the system of so many thousands, are effectually destroyed and removed. ☞ SEND FOR A CIRCULAR. ☜

Important to Assayers.

Crucibles.

The Patent Plumbago Crucible Co.

Manufacturers of all kinds of
Melting Pots, Portable Furnaces,
CRUCIBLES, and other fire-standing Goods,
Battersea Works, London.

THE MORGAN PATENT CRUCIBLES have uniform quality, never crack, withstand the greatest heat without danger; heats more rapidly than any other; change of temperature has no effect on them; stand on the average forty to fifty pourings.

CERTIFICATES:

United States Branch Mint, San Francisco, Cal., March 12, 1869—Messrs. A. S. Hallidie & Co., Agents Morgan Crucible:—I have carefully tested the Morgan Patent Plumbago Crucibles purchased from you for the U. S. B. Mint, and cheerfully certify to their superiority and economy over all other Crucibles used by and under me. They are fully what you represent them, and I shall continue to use them in preference to any other. J. M. ECKFELDT, Melter and Refiner, U. S. B. Mint.

Eagle Brass Foundry, 206 Fremont street, San Francisco 12th March, 1869—Messrs. A. S Hallidie & Co., 519 Front street—Gentlemen:—We have used and tested the Morgan Patent Plumbago Crucible, for which you are agents, and pronounce them superior to and cheaper than any Crucible used by us heretofore. GREENBERG & MOORE.

Messrs. A. S. Hallidie & Co :—We have thoroughly and severely tested in every way the Morgan Patent Plumbago Crucible obtained by us from you, and find them superior to any we have yet tried, although we have used every pot obtainable in this market, we have none equal to the above, and concede your claims for them. We think they will average 45 pourings of brass.
GALLAGHER, WEED & CO.,
California Brass Works, 125 Front street, San Francisco.

Assay Office of H. Harris, Silver City, Nevada, April 24, 1869—Messrs A. S Hallidie & Co.—Gents.:—I received from you three Crucibles of the Morgan make, which I have used since their arrival, and tested by constant use. Since 1847, when in the New Orleans Mint, I have always preferred the Crucible of Dixon's make over Adus, Gautier, and Taunton, Mass. Yours I find to be not alone of more finished make, but to stand double or treble the work of Dixon's Crucibles. The No. 12—the smallest sent—has stood so far 32 meltings, and is as good and sound as when received. Your Crucibles do not scale off like others; and as they are forty per cent. cheaper, I do not see why they should not be preferred by all assayers on account of durability and cheapness. Yours respectfully, H. HARRIS.

On hand and for sale by the Agents,
A. S. HALLIDIE & CO.,
18v18-9p 519 Front street. San Francisco

Sheffield Scientific School

Of Yale College, New Haven, Conn.

This department of Yale College, instituted in 1840, and endowed with the National Land Grant in 1866, furnishes advanced instruction in the various branches of Mathematical, Physical, and Natural Science.

The School is under the direction of the President of the College, a Board of thirteen Professors in differe specialties, and six assistant instructors.

Regular courses of study, leading to the degree of Bachelor of Philosophy, conferred by Yale College, are arranged as follows: 1—CHEMISTRY AND MINERALOGY. 2—CIVIL ENGINEERING. 3—MECHANICAL ENGINEERING. 4—MINING ENGINEERING AND METALLURGY. 5—AGRICULTURE. 6—NATURAL HISTORY AND GEOLOGY. and 7—SELECT COURSE.

Advanced students are also admitted to optional courses, and if already College graduates, are received as candidates for the degree of Doctor of Philosophy.

Tuition, $125 per year of forty weeks.

The Libraries, Museums, Laboratories and Apparatus accessible to students, are varied and extensive.

For copies of the Annual Circular and Report, letters may be addressed to the "Secretary of the Sheffield Scientific School," New Haven, Conn. v16-1y16p

WIESTER & CO.,

PATENT BROKERS,

No. 314 Bush Street, San Francisco.

PATENTS BOUGHT AND SOLD ON COMMISSION.

For the benefit of those who live at a distance from the city, we give below a brief description of a few of the valuable Patents which we have in our office. It may be well to state here that no Patent is received by us for negotiation until it is first endorsed by reliable experts, to whom each is subjected for acceptance or rejection. We treat all patents alike, recommending only where true merit is found in the invention.

Odermatt & Ettlin's Fountain Pen.

PAT'D. AP. 6. 1869.

We call the attention of manufacturers to this new invention for supplying writing and drawing pens with a constant flow of ink. The pen-stalk contains sufficient ink to last for two or three days' constant use, and is provided with stop-cocks, which make it perfectly safe for carrying in the pocket. The flow of ink is under perfect control of the operator. A slight pressure on the thumb and fore-finger on the elastic sides of the holder is all that is required to regulate the flow of ink to suit the writer. It never blots unless forced to do so. The cost to manufacture is small, and the demand for a good Fountain Pen is very extensive among all classes of literary and business men. A sample of this invention can be seen and tried at our office, 314 Bush street, San Francisco. The entire Patent, or the Right for any State, can be bought on reasonable terms. Full particulars furnished on application.

NEW LIGHT ON A NEW PRINCIPLE.

Gas for everybody in the city and in the country. Equal to coal gas at one-half the cost. The gas is generated and burned in a new style Vapor Lamp. No wick, no chimney, no explosion; and no man who is out of business and has a few dollars should fail to purchase a County or State Right and commence making money. Parties owning territory get the Lamps at Manufacturers' prices. Call and examine the light, or write for particulars.

A NEW PAPER FILE AND MUSIC FOLIO.

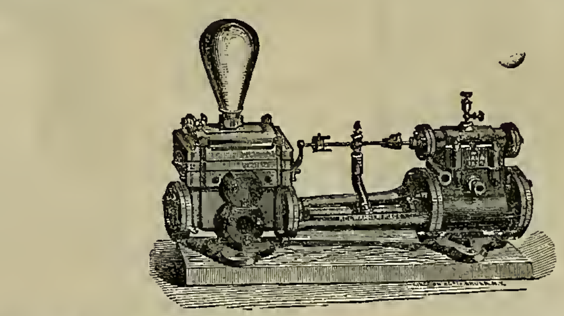
Two excellent inventions included in one patent. Either can be manufactured at a small cost, and neither has an equal in its line. No more expense for binding music. Each sheet has a complete and durable binding as soon as it is placed in the folio. The California Legislature has endorsed the Paper File by purchasing three hundred and fifty, to take the place of the old style binders. It certainly is the most complete article of the kind ever invented. Whoever buys the right to manufacture and sell this invention will secure a good basis for a profitable business. Only the Territory west of the Rocky Mountains for sale. Parties in the city should call and examine the article. Full particulars furnished on application.

WIESTER & CO.,
314 Bush Street, San Francisco.

LOCAL AGENTS WANTED.

One reliable business man wanted in each and every town on the Pacific Coast to sell Patent Articles. We deal in none but first-class Patents, and each agent receives the exclusive right to sell in his town. Address
WIESTER & CO.,
314 Bush street, San Francisco.

KNOWLES' PATENT STEAM PUMP.



This Pump has received the HIGHEST PREMIUM at every Fair where it has been exhibited. It is of superior make and finish; has all ground joints; no packing required. It is positive in its action It is impossible to stop it on centers. It will always start without using a starting bar. We have two hundred different styles and sizes adapted for Factories, Steamships, Sugar Refineries, Breweries, Distilleries, Gas Works, Oil Works, Soap Works, Paper Mills, Tanneries, Bleacheries, Laundries, Railroad Purposes, Quarries, Petroleum Mines, Drainage, etc. Large Pumps for Water Works. Fire and Wrecking Pumps. ☞ Pumps guaranteed for every situation.

E. T. STEEN & V. CUSHING,
SOLE AGENTS FOR THE PACIFIC COAST,
No. 9 FIRST STREET. SAN FRANCISCO.

NEW AND SECOND-HAND ENGINES, BOILERS, and MACHINERY OF ALL KINDS, constantly on hand.

PACIFIC
Rolling Mill Company,
SAN FRANCISCO, CAL.

Established for the Manufacture of
RAILROAD AND OTHER IRON
—AND—
Every Variety of Shafting,
Embracing ALL SIZES of
Steamboat Shafts, Cranks, Piston and Connecting Rods, Car and Locomotive Axles and Frames
—ALSO—
HAMMERED IRON
Of every description and size.

☞ Orders addressed to PACIFIC ROLLING MILL COMPANY Post Office, San Francisco, Cal., will receive prompt attention.

San Francisco, Saturday, May 7, 1870.

VOLUME XX.
Number 19.

The Diamond Pointed Drill.

It has long been well known that good progress could be made in rock-boring by using a rotary cutting action. The first machines of the kind were scarcely more than a sort of auger, yet they gave such results and offered such advantages over the common striking tool, especially in the matter of repairs, that there were many who predicted at the time that rotary machines would be improved so as to supersede all others.

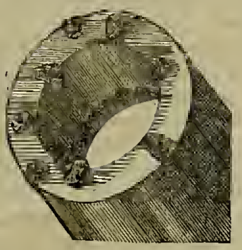

Fig. 1.

A most important step was made when in 1860 Prof. R. Leschot, a French engineer, conceived the idea of setting diamonds in an annular cutter. Before, these machines could be used in soft rocks; now they bid fair to be effective on the hardest. Leschot found that by arranging diamonds in his ring-shaped bit or boring head, as shown generally in Fig. 1, so as to cut out a core, he could work very rapidly and economically. His patent rights have become the property of Messrs. Severance and Holt, who are practical mechanics, and who have been long at work making improvements. They have rendered more secure and convenient the setting of the diamonds, increased the speed, and regulated the feed gear so as to adjust the feed to the varying hardness of the rock. They have added the swivel head, so that the drill may work at any angle, and have substituted the hollow screw shaft, besides making various other improvements. They have several styles of drill, the most common of which we illustrate. Fig. 2 shows a "No. 1 prospecting drill," so called, because of its general use in testing the character and value of mines and quarries. It consists of a small upright boiler, to one side of which is firmly bolted the cast-iron frame which supports the engine, A,—an oscillator of from five to seven horsepower—and swivel drill-head, gears and screw-shaft, B, with drill passing through it, as shown in the engraving. This shaft is made of hydraulic pipe from five to seven feet in length, with a coarse thread cut on the outside. This thread runs the entire length of the shaft, which also carries a spline by which it is feathered to its upper sleeve-gear. This gear is double and connects by its lower teeth with the beveled driving-gear, and by its upper teeth with the release-gear, E. This release-gear is feathered to the feed-shaft, F, at the bottom of which is a frictional gear fitting the lower gear on the screw-shaft, which has one or more teeth less than the frictional gear, whereby a differential feed is produced. This frictional gear is attached to bottom of feed-shaft, F, by a friction-nut, thus producing a combined differential and frictional feed, which renders the drill perfectly sensitive to the character of the rock through which it is passing, and maintains a uniform pressure upon the same. The severe and sudden strain upon the cutting-points, incidental to drilling through soft into hard rock with a positive feed, is thus avoided. The drill proper (passing through the screw-shaft, B), consists of a tubular boring bar, made of lap-weld pipe, with a steel bit or boring-head, D, screwed on to one end. This bit is a steel thimble about four inches in length, having three rows of black diamonds in their natural rough state firmly imbedded therein, so that the edges of those in one row project forward from its face, while the edges of those in the other two rows project from the outer and inner peripheries respectively.

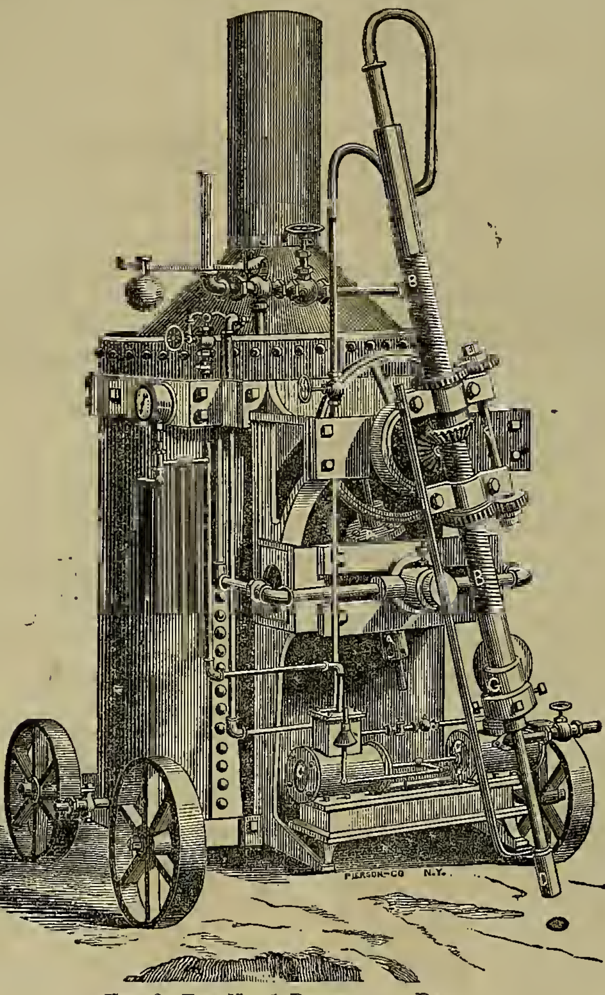

Fig. 2—The No. 1 Prospecting Drill.

The diamonds of the first-mentioned row cut the path of the drill in its forward progess, while those upon the outer and inner periphery of the tool enlarge the cavity around the same, and admit the free ingress and egress of the water as hereafter described. As the drill passes into the rock, cutting an annular channel, that portion of stone encircled by this channel is, of course, undisturbed, and passes up into the drill in the form of a solid cylinder. This core is drawn out with the drill in sections of from eight to ten feet in length.

The sides of the hollow bit are one-fourth of an inch thick, and the diamonds of the inner row project about one-eight of an inch, so that the core or cylinder produced by a two-inch drill (the ordinary size for testing), is one and a quarter inches in diameter.

Inside the bit, D, is placed a self-adjusting wedge, which allows the core to pass up into the drill without hindrance, but which impinges upon and holds it fast when the action of the drill is reversed—thus breaking it off at the bottom and bringing it to the surface when the drill is withdrawn. In order to withdraw the drill it is only necessary to throw out the release gear, E, by sliding it up the feed-shaft, F, to which it is feathered, when the drill runs up with the same motion of the engine which carried it down, but with a velocity sixty times greater; that is, the speed with which the drill leaves the rock, bringing the core with it, is to the speed with which it penetrates it as sixty to one—the revolving velocity in both cases being the same. The drill-rod may be extended to any desirable length by simply adding fresh pieces of pipe. Common gas pipe is found to serve admirably for this purpose, the successive lengths being quickly coupled together by an inside coupling four inches long, with a hole through the center of each to admit the water. The drill is held firmly in its place by the chuck, G, at the

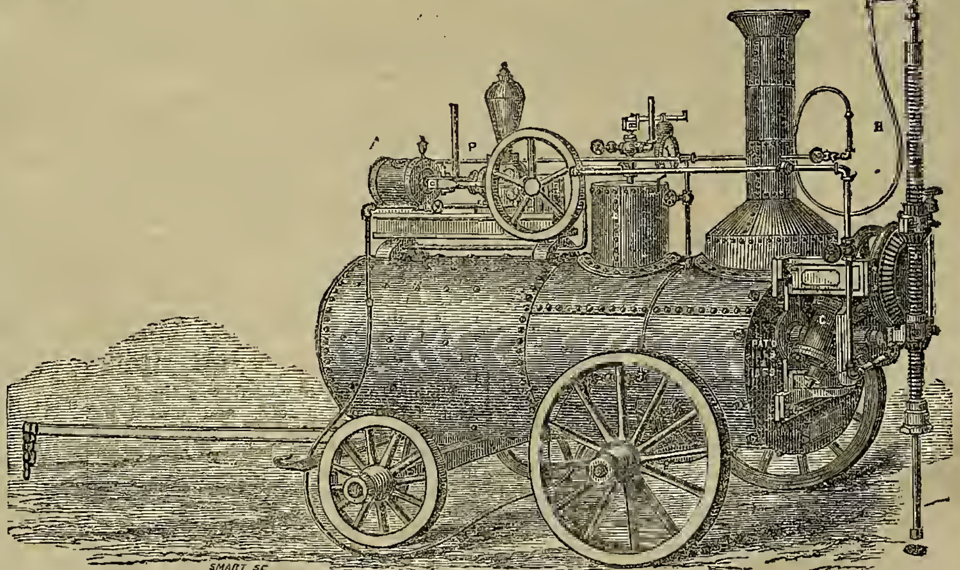

Fig. 3—No. 2 Prospecting Drill.

[Continued on page [illegible]03.]

The San Francisco Mint—Getting the Pure Metals.

In making money—that is, in transforming the crude bullion into the glittering specie—there are two distinct processes required; viz: first, purifying and separating the precious metals, and running them into proper bars and ingots; and secondly, subjecting these bars to operations in a great measure mechanical, such as rolling and stamping, by which they are shaped into coins. Only the first is performed in the "Assay Offices" of the Government, but both are done at the Mint.

Those persons in or near the city who are curious to see exactly how the precious metal is treated, can satisfy themselves by paying a visit to the Branch Mint here between the hours of nine and twelve in the morning, when they will be shown the whole of the works and have the details explained by the gentlemanly conductors of the institution. And if those of our readers who are too distant to visit the place in person will accompany us in spirit, we will endeavor to denote the various processes in a trip through the establishment, which we lately made by the kind permission of the superintendent, General La Grange, and under the special charge of Mr. Sam. Mayer, so well known in musical circles.

Weighing and Melting Rooms.

Our steps lead us first to the weigh-room, whither depositors bring the metals in the most varied shapes, and for which they get a receipt certifying the weight and apparent character of their deposits and the value of which they are paid as soon as this has been ascertained by assay. In this room our attention is attracted principally by the huge scales, strong enough to weigh at once some two thousand ounces, and yet sufficiently delicate to turn with the hundredth part of an ounce.

The bullion, having been weighed on these scales, and given a number, is placed in copper-lined boxes, together with a paper stating its number, character and weight. A similar but fuller account is entered in the books, and the deposit is sent down on a small railway to the room below—the melting room. Henceforth it is known only by its number.

We may as well remark here on the great strictness exercised to prevent any loss of precious metal. After every operation the bullion is carefully weighed so that it is impossible for any to be lost without the knowledge of the book-keeper, the head of the separate departments and all who have access to the books; and if any is unaccounted for, the operators in the process where the loss occurs are not allowed to leave the building until this is made up.

These and other regulations are so strictly observed that there is no possibility of dishonesty on the part of the employés, and any person who has heard stories of immense losses at the Mint need only to visit the place to be convinced that these stories cannot be true.

In the melting-room are several iron furnaces which contain crucibles buried in the red-hot coals. In these crucibles, together with a little borax and perhaps also some saltpetre—the latter only when the bullion is very impure—the gold is melted. When it has become thoroughly fluid and mixed, it is poured out into molds and cooled. Then its number is stamped on it, any grains collected from the flux, which is powdered for this purpose and the grains of metal taken out, are added to it, and it goes back to the weigh room, where it is weighed under official supervision to ascertain the loss in melting.

Assaying.

The bullion can now be assayed. This could not have been done previously on account of dirt which it might have contained, it not being homogeneous, etc. After the assay the depositor can get his money, receiving the full value, *minus* one per cent. for refining and coining charges.

As the process of assaying is generally understood, but a brief description is necessary. From opposite corners of our gold bar two assay pieces are clipped, taken to the assay room, hammered, and rolled into slips, and marked to show to what deposit they belong. One-half gramme (about one-sixtieth of an ounce) is accurately weighed out, twice the amount of pure silver and a small piece of pure copper wire added, the whole wrapped up in a piece of lead foil—about ten times as heavy as the gold and silver—and this sent to the furnace to be cupelled. The silver is added because in the process of parting the gold and silver it is necessary to have between two and three times as much silver as gold, else the acid will not be able to get at all the silver. The copper makes the gold tough, and by retarding the oxidation in cupelling, gives time for this to occur more perfectly. After cupellation the button is weighed and the silver dissolved out by nitric acid. In our California gold there is often quite an amount of iridium, which is now easily perceived as a black substance remaining undissolved with the gold.

Up to this time each deposit has been kept separate from all others; but now that its value is known this is no longer necessary, and it is mingled with others as required.

Parting the Gold and Silver.

In the melting room, whither our gold now goes, two parts of silver are added, for the purpose stated above, and a large amount is melted in a crucible and then dipped out and tossed with a peculiar jerk into a tank of cold water. The result of this last is, that it is obtained in the tank in granules or drops similar to pop-corn, which, by exposing a large surface to the action of the acid in the next process, shortens the time required for dissolving. The water is drained off and the metal carried to the parting room.

Here we see closets with sliding windows, arranged for carrying off the acid fumes, which we may often see issuing from the chimney as a dark brown smoke. In these closets are large porcelain jars, holding about twenty gallons each, which are set in water tanks and heated by steam pipes. Some 150 pounds of the metal are placed in each jar, about 10 gallons of nitric acid (of 38° Beaumé) added, and the whole kept boiling for six hours. Then the greenish solution of nitrate of silver is removed to a large tank, the gold is washed clean with warm water in a tub, whose bottom is a strainer composed of muslin and filtering paper, the wash water added to the rest of the nitrate of silver, and the gold, which is in the form of a dark brown powder, taken to a hydraulic press and subjected to a pressure of some two hundred tons, which forces out all remaining water and leaves us a solid cake, 12 inches in diameter and three inches thick, weighing about sixty pounds and worth eighteen or nineteen thousand dollars.

Our cake is now baked or dried in an oven, then melted in a crucible with a little borax and saltpetre, to get out any base metal, and then cast into bars some 16 inches long, an inch wide and half an inch thick, with a wedge shape end. This is numbered, and is now ready for coining.

Into the tank containing our nitrate of silver is led a strong solution of common salt. The silver is precipitated as a white wooly mass of chloride. When this precipitate no longer forms, and this is tested in a small becker glass, the solution is drawn off and the silver chloride is washed or "sweetened" with water in tanks with bottoms which form filters.

After being thoroughly washed, the chloride is placed in a large leaden vat in which is put water and granulated zinc. Here is formed metallic silver and chloride of zinc, the latter being soluble in water. Any small excess of zinc is dissolved by adding a little sulphuric acid and the solution is drawn off and thrown away. The silver, after being properly washed, is put in the hydraulic press and formed into cakes the same as the gold, and can be melted into bars or be used again in refining gold.

[TO BE CONTINUED.]

* * *

To Mend Rubber Hose.—Wm. Hunt, New York City, writes the *Club*: "The inclosed method of mending rubber hose ought to be known to everybody. I mended mine in several places two or three years ago, and it is yet strong and good. The plumbers said there was no other way but to use couplings costing a dollar each. I used iron pipe, cut to order, three inches long, costing three cents each. Cut the hose apart where it is defective; obtain from any gas-fitter a piece of iron pipe two or three inches long; twist the hose over it until the ends meet, wrap with strong twine, well waxed, and it will last a long time."

Mining in Humboldt County, Nevada.

[Written for the Scientific Press.]

Editors Press:—Battle Mountain Station, on the Central Pacific Railroad, 384 miles from Sacramento, is the stopping place for visitors to the Battle Mountain mines, some seven miles distant, and the depot of distribution for the surrounding country. Those bound for the mines secure here a seat in one of Mr. J. A. Blossom's fine coaches, which run to the mines, seven miles, and to Galena, seventeen miles distant, and enable one to make the trip quickly and with ease. Mr. Blossom has, moreover, a fine livery stable, and has also five large teams at work hauling ores for shipment to San Francisco or Liverpool.

Old Battle Mountain takes its name from a battle fought between a band of emigrants and a party of Indians, and the railroad station is named from the mining camp. The citizens of the latter place have, however, to prevent confusion, determined to change its name to Safford, in honor of the Governor of Arizona, who was formerly of Humboldt.

The mines here are chiefly of copper and galena, and are very rich in silver, with gold in some instances. The first acquaintance I made here was Mr. G. W. Fox, who, with Mr. R. McBeth, discovered the mines in 1867. These gentlemen were prospecting in the district and lost their horses. In the hope of being able to get a view of the animals they ascended a high mountain and came across the lead known now as the Little Giant.

Little Giant Mine and Mill.

Through the kindness of the Superintendent, Mr. A. Morrison, I was enabled to go through this mine, which has been worked steadily since that time. The ledge, which is well defined, is about one to three feet wide, and runs north 50° west with a dip of 50° to the southwest. The ore is rich in chlorides, and here and there in sulphide of silver.

We went in on tunnel No. 4, which extends in 150 feet on the ledge. Above this is tunnel No. 3, 190 feet long, then No. 2, 175 feet, and then No. 1, the distance from which to No. 4 is 500 feet. These are all on the ledge, and the work is carried on by stoping from one to the other. From what I have seen I think I am just fied in calling the mine one of the most promising of the district.

Two miles from the mine is the company's 5-stamp mill, run with a 25-horse power engine. Sagebrush is used as fuel. They are working with one Horn and two Wheeler pans and two large settlers, and anticipate setting up five extra stamps at an early day. The stamps run only during the daytime; the pans are at work day and night. The rock has averaged, I am told, $250 per ton for many months. I saw also at this mill Mr. U. Harris, who is working the tailings with the Evans patent riffles, which are giving some very good results and paying handsomely.

The Alaska and the Mary Ann.

Leaving the Little Giant we passed on over to the side of a mountain still larger than the one I left, and visited the Alaska mine. This is owned by D. B. Higgins & Co. Mr. Higgins, who is Recorder of the district, has been some eight years in Humboldt county, but has concluded to locate in this particular spot. His ledge is four feet wide and he has sunk down thirty-five feet, having a fine body of ore in sight all the way down. A contract has just been made for sinking 15 feet deeper, and the ore will be shipped to San Francisco for smelting.

The next mine we visited was the Mary Ann, taken up in 1868, and owned by Heintzlemann & Co. The vein appears very well, eight men being employed on it. Twenty tons have been sent to Mr. Fox's mill for treatment, but as this was being worked at the time of my visit, I cannot give the result. The ore assays well.

This is a very promising camp, which has sprung up within the last six months, and now contains a hotel, a blacksmith shop, a 5-stamp mill and about twenty-five houses. There are here about 150 men. Through the place runs a fine spring, furnishing a supply of excellent water. From here we ride further in Blossom's comfortable coaches to Galena. W. H. M.

Earthquakes in the Mississippi Valley.

A series of earthquake-shocks occurred in the Mississippi Valley at the close of 1811, continuing to 1813, which were violent enough to modify its surface to a considerable extent, converting dry land into lakes, some many miles in extent, raising low lands and creating yawning fissures. New Madrid, Missouri, appears to have been one of the foci of the disturbance, and here the shocks were repeated almost hourly for months in succession. The region being but sparsely inhabited, and the houses being mostly log cabins, the destructive force was not felt to so great an extent as if there had been a dense population, but the shocks were severe enough to have made such a city as San Francisco a mere mass of ruins.

Foster, in his work on the Mississippi Valley, has collected several descriptions of the shocks. The first occurred on the night of the 16th of December, 1811. About midnight, while the major part of the population of New Madrid were engaged in dancing and frollicking, the shock came with sufficient violence to shake down many of the houses. The greatest consternation prevailed. The entire population rushed into the open air; and there, in the midnight darkness and upon the rocking earth, Protestant and Catholic knelt side by side and offered supplications to the Mightiest.

The shocks extended over a period of twenty or thirty months. Sometimes they would come on gradually and finally culminate, and sometimes they would come suddenly with terrific force and gradually subside. In every instance the motion was propagated from the west or southwest. Fissures were formed six and even seven hundred feet long and twenty or thirty feet broad, through which water and sand would spout to the height of forty feet. There issued no burning flames, but flashes, such as result from the explosion of gas or from the passage of the electrical fluid from one cloud to another. Trees were often split in the center and left with one part standing on one side of the fissure and one part on the other. Whole tracts were covered with water which, when it retired, left a stratum of sand on the land which destroyed its value. As the concussions continued and the rumbling noises and explosions, the birds themselves lost all power and disposition to fly, and retreated to the bosoms of men. A few persons sank in the chasms, one died of fright, and one perished miserably on an island which retained its original level in the midst of a wide lake created by the earthquake. Houses were swallowed up, and often men were saved from the same fate by having felled trees at right angles to the fissures, and placed themselves on the trunks. So great was the destruction of property and so irretrievably ruined were many of the farms that Congress subsequently passed a law granting to each proprietor who had sustained a heavy loss, a section of land in the "Boon-Lick country" in exchange for his desolated farm.

Earthquake shocks still occur in this region, and blasts of air and gas yet find their way to the surface through many of the half-filled fissures; but there has been no repetition of the terrible phenomena witnessed in 1811-12.

* * *

Significant.—It is estimated that the aggregate amount of money deposited in all the savings banks of the United States is five hundred millions of dollars. An equal distribution would give each man, woman and child twelve dollars and fifty cents. The savings banks of San Francisco hold deposits amounting to over $29,000,000, or at the rate of $170 to each inhabitant—thirteen times more than the general average for the United States.

Lime spots on woolen clothes may be completely removed by strong vinegar.

Mechanical Progress.

Condensing Steam Donkey Pump.—*Engineering* for April 8th illustrates a new and ingenious pump of this kind, which is a French invention. We quote a portion of the description: "The main feature in this donkey pump—constructed by Claparède & Co., of St. Denis—is, that it is so arranged that the whole of the steam employed to work it is condensed by the water which it forces into the boiler, the heat of this steam being thus utilized as it is in Giffard's injector. * * The exhaust port of the steam cylinder communicates with a pipe, which passes up through a water casing formed by the suction pipe of the pump, and is fitted at its upper end with a valve, kept in its place by a light spring. At each stroke, as soon as the pressure in the suction pipe of the pump is less than that in the exhaust pipe, this valve opens and allows the exhaust steam to come into contact with the water, which is on its way to the pump, when, of course, it is instantly condensed, and thus communicates its heat to the water. At the same time a partial vacuum is produced behind the piston, the amount of this vacuum depending upon the height from which the pump is drawing water, and being, of course, always something less than the vacuum due to that height."

New Flux for Iron and Steel Welding.—The Philadelphia correspondent of the *Iron Age* gives, April 21st, a report of some experiments with a new flux recently purchased by the Pennsylvania Railroad Co. Among them were the following: Twenty-four Bessemer rails, two feet long, were piled and welded solid into an ingot weighing 732 lbs. A 60-inch Krupp's steel tire, 5⅜ inches wide and 1⅝ thick, was welded solid at two heats, and then broken only under hydraulic pressure of 35,000 lbs. A Vicker's steel axle was cut into and welded with a forked weld, and when cold subjected to a hydraulic pressure of 120 tons, which *bent it*, and then to a reversed pressure of 115 tons which broke it *across the weld*. Steel was burned until it crumbled, and restored to its original strength by dipping it in the melted flux, heating and hammering it.

Some experiments with this flux were also tried at Hos's Works, in New York. Welds were made of cast steel to malleable cast iron, and of the highest tempered cast steel to itself and to iron, and, further, of ⅜inch *copper rods* together. This latter operation, as the experimenter states, quite "brought down the house."

Mushet's Tool Steel.—A correspondent of *Engineering* says that having an extensive order for street rails, each requiring twelve ⅝-inch holes to be drilled, and being pressed for time, so that the drills had to be run at a high speed, it was found that hard skin upon the rails would turn the finest special Sheffield steel before it was possible to finish a single rail, and often by the sixth hole. Mushet's tool steel,—of which we have already spoken in the Press,—was tried; and a single drill carefully prepared completed nine rails, or 108 holes, before the edge was turned. The average number, however, was between 40 and 50.

Forty Years Ago.—At a late meeting of the Foremen Engineers, Sir J. Whitworth, in the course of some remarks upon the mechanical progress during the last forty years, particularly in the construction of self-acting machinery, said that twelve shillings per foot was then paid for the labor of chipping and filing iron surfaces. The same work is now frequently done on the planing machine for one penny.

New Propeller.—A new device separates the screw into three parts, one of which is keyed to the shaft, and the others made so as to work freely upon it. When in use, the three are secured together, forming a complete screw. When not required for the propulsion of the vessel, they are disengaged and secured in a line with each other; thus presenting a minimum surface of resistance.

Steel Car Tires—How Made.—"Mr. Ramsbottom, of the iron works at Crewe, England, casts his tire ingots in the form of a truncated cone, a usual size being two feet diameter at the bottom, six inches at the top, and thirty inches in height. This he hammers on its ends and sides till it assumes the shape of an ordinary flat cheese, with a thickness of about twelve inches. Another heat is taken on it, and it is then placed under a steam hammer furnished with a pointed conical tool, and by successive blows with this on both sides a hole is forced through the center of the disk, and this again expanded as the hammering proceeds, till the upper part of the tool, which is flat, comes down upon the tire and consolidates the metal by reducing its thickness. A third heat is then taken, and the ring so formed is placed over a stout beck projecting from the inclined side of an anvil, which maintains the ring in such a position as to give a suitable bevel to the outer face when struck by the hammer, while at the same time its diameter is considerably increased by the operation. After this third hammering it is ready for the tire rolls, and a fourth and last heat is taken for that purpose."—*Slade's Report.*

Band Saws for Cutting Metal.—The *Engineer* for March 25th describes a large machine of this kind recently built at Chelsea for Krupps' steel works at Essen. The table is eight feet square. The blade works around two pulleys at rates variable from 200 feet to 250 feet per minute, and passes through guides to keep it from swerving. The bottom pulley dips into a trough of soap and water, to keep the saw as cool as possible. The material is fed up to the saw through the agency of a lever attached by a chain to the guide just above the table. This machine is capable of cutting through ¾-in. plate at a speed of from 4 feet to 6 feet an hour, and ⅜-in. plate at about 10 feet an hour. When cutting large plate, iron balls are generally inserted between it and the table; this lessens friction and brings the material more completely under the control of the operator. The saw will, in average work, run from four to five hours without re-sharpening.

New Form of Hydraulic Press.—In the testing machines of MM. Desgoffe and Ollivier, of Paris, which are attracting some attention at this time, hydraulic power is employed. The manner in which their presses differ from those in ordinary use, is thus referred to by *Engineering:* "In ordinary hydraulic presses, the pressure is obtained by forcing into the press cylinder successive increments of water, whereas, MM. Desgoffe and Ollivier employ a constant quantity of water and obtain the requisite pressure by forcing into this water a solid body. The principal advantage of this system, to which they have given the name of *sterhydraulique*, is, that it enables the pressure to be increased with perfect steadiness instead of by a series of jerks, as is the case when an ordinary hydraulic press and pump are employed; and in the case of testing machines this is a matter of importance."

Manometer for Furnace Gases.—Bessemer measures the pressure of the gases in the pressure-furnaces for steel manufacture, by means of a manometer consisting of a vessel containing quicksilver, fastened to the outside of the furnace, and connected with the inside by an iron pipe open at both ends. The pressure of the gases causes the quicksilver to rise into a graduated glass tube, in the top of the vessel. A little stream of cold air is admitted from the blast-pipe into the iron tube, which prevents the heating of the quicksilver.

To Recover the Silver from Photographic Baths.—The following method is recommended by the *British Journal of Photography:* Dissolve oxalic acid in water and render the solution alkaline by carbonate of soda; make the silver bath also alkaline in the same way and add to it oxalate of soda as long as any precipitate is formed; collect the oxalate of silver thus thrown down upon a filter, dry, and mix it with equal weight of bicarbonate of soda in a Hessian crucible, and expose to strong heat in a furnace. The reduction takes place easily, and the silver will be found as a brilliant regulus in breaking the crucible.

Scientific Progress.

Hydrogenium-Amalgam.

The following is part of a paper read April 11th before the New York Lyceum of Natural History, by Oscar Loew, Chemical Assistant in the College of New York:

"When zinc-amalgam is shaken with water a slow decomposition of the latter takes place, which can be recognized by the formation of flocculi of hydrated oxide of zinc, and by small bubbles of hydrogen which escape, after the mixture stands for a time. The decomposition of water by zinc is intensified when a small amount of bichloride of platinum is added, in which case a spongy body is formed on the surface of the zinc-amalgam. This body I have found to be an alloy of hydrogenium and mercury. Hydrochloric acid does not act in a way similar to bichloride of platinum. * * The body thus obtained has the consistency and appearance of the ammonium-amalgam, and slowly develops hydrogen under water, as well as in the dry state; by which decomposition the volume will be found to have considerably increased. On heating it in a vessel containing air, it swells up and water is directly formed, the hydrogenium combining directly with the oxygen of the air. The marked reducing power of hydrogenium found by Graham in the palladium-hydrogen alloy may be observed here also. Ferridcyanide becomes ferrocyanide; perchloride of iron becomes protochloride. It has been a supposition of several chemists that the so-called ammonium-amalgam may be hydrogen-amalgam mixed with absorbed ammonia, and I found, indeed, that ammonia is taken up by hydrogenium-amalgam to a certain extent; but the behavior towards acids, and the investigations of Landolt and of our American chemist, Dr. Gallatin, have shown the existence of true ammonium-amalgam; so that these bodies are certainly not identical."

Isopurpuric Salts in Dyeing.—The *Journal of Applied Chemistry* translates from the German of C. Zulowsky an article upon the above subject, from which we quote: Under the term "Grenat soluble" (soluble garnet), a dye prepared by Casthelaz, in Paris, is stated to be the ammonia salt of the isopurpuric acid, which, as is known, is formed by the action of a soluble cyanogen metal upon picric acid. It is not prepared from the pure crystalized, but from an inferior kind of picric acid, and is probably destined to replace the archil in many cases, in imparting to wool all shades from garnet to chestnut brown. It may be readily combined with other pigments, so that a number of different colors may be obtained. According to Casthelaz, the dyeing of wool and silk is effected by the addition of an organic acid to the bath; for instance, acetic or tartaric acid, mineral acids being excluded. The dye bath for silk should be cold or tepid in the beginning. Different shades in red and brown are thus obtained that are dependent upon the concentration of the bath, the nature of the mordant and the time of the operation. These colors are exceedingly brilliant, similar to those that are obtained with archil, yet they are more stable when exposed to light and air.

Gas and Liquid States Continuous.—Dr. Thos. Andrews recently read a paper before the Royal Society, giving an account of extended experiments, from which he concludes that the gaseous and liquid states are only widely separated forms of the same condition of matter, and may be made to pass into one another by a series of gradation so gentle that the passage shall nowhere present any interruption or breach of continuity. From carbonic acid as a perfect gas to carbonic acid as a perfect liquid the transition may be accomplished by a continuous process, and the gas and liquid are only distant stages of a long series of continuous changes.

Antiquity of Man in North America.—In a paper on this subject by Dr. J. W Foster, published in the Transactions of the Chicago Academy of Sciences, he says, in summing up the proofs, that "the discovery by Prof. Whitney, of a human skull in California buried deep in the gold drift, and covered with five successive overflows of lava, carries back the advent of man to a period more remote than any evidences thus far afforded by the stone implements in the drift of Abbeville and Amiens, in the valley of the Somme, or the human skeleton in the loess of the Rhine."

Graham on Diffusion of Gases.—The following is an extract from the address of Prof. Williamson at the anniversary meeting in London of the Chemical Society on March 30th. He is speaking of Prof. Graham, whose scientific labors constitute the especial subject of the address at this the first annual meeting since his death: "The line of research which occupied most of his attention, and in which his results were perhaps the most important, was that of diffusion ; and it would be difficult to overestimate the importance to molecular chemistry of his measurements, of the relative velocities of these spontaneous motions of particles of matter, whether in the state of gas or in the liquid state. It was known that one part by weight of hydrogen occupies the same volume as sixteen parts by weight of oxygen when measured at like temperature, and under like pressure. Chemical investigations prove that these equal volumes of the two gases contain the same number of atoms. We also know that the atoms in such a gas are in rapid motion, and resist the pressure to which the gas is at any particular time exposed by striking against the surface which presses them together, with force equal to that which presses them together. Thus a given volume of hydrogen is maintained against the atmospheric pressure by an energy of atomic motion equal to that of the same volume of oxygen. Each atom of hydrogen accordingly exerts a mechanical energy equal to that of each atom of oxygen; but we have seen that the hydrogen atom is much lighter than the oxygen atom, and accordingly it must move with much greater velocity than the oxygen atom.

Now Graham allowed hydrogen to escape through a very small hole in a plate of platinum, and allowed oxygen to escape under similar circumstances. He found that each hydrogen atom moves out four times as fast as each oxygen atom. His experiments were so arranged as to enable him to measure the relative velocities of certain motions of the atoms—motions not imparted to them by any peculiar or unnatural conditions, but belonging to them of necessity in their natural state. He found, moreover, that heat increased the velocity of these atomic motions, whilst increasing the force with which a given weight of the gas resists the atmospheric pressure."

Walling and Van der Weyde.—We quote a paragraph from Dr. Van der Weyde's last answer to Prof. Walling, in the *Chemical Repertory*,—giving side by side the ideas of both in reference to the cause of motion. We have before made allusion to the discussion:

"That I also say, with Prof. Walling, that motion of matter must have a cause, is evident, my primary cause being gravitation, inseparably associated with matter; Prof. Walling's cause being a force filling the whole universe naturally dissociated from matter, but which occasionally becomes associated with it, and occasionally not; in the first case it manifests itself as gravitation or otherwise; in the second case it does not manifest itself at all, but still exists, 'acting in every direction, and thus according to the law of the composition of forces, its resultant will be zero.' Paired atoms 'intercept a portion of the force and consequently have a mutual tendency towards each other; this is the whole principle of gravitation."

National Academy of Science.—The semi-annual meeting of this body was held in Washington from the 12th to the 16th ult. Among the most valuable papers read were, one by Prof. Gibbs on the measurement of wave lengths; by Prof. Newcomb on the coming transit of Venus; by Mr. Hilgard on the measurement of meridional arcs; by Dr. Newcomb on the moon's mean motion; by Prof. Harkness on the deviations of the compass in iron ships, with a very complete set of experimental observations; and one by Prof. Poey on a new explanation of clouds, to be published by the Smithsonian Institution with full illustrations.

It is said that copper workers are apt to get their gums stained green, and that their perspiration is of a bluish green hue. This, however, seems to do them no specific injury, but, on the contrary, to preserve them from the attacks of cholera.

Mining Summary.

The following information is gleaned mostly from journals published in the interior, in close proximity to the mines mentioned.

California.

ALPINE COUNTY.

Mining Items.—*Miner*, April 23d: The rock in the Globe tunnel is working better and it cannot be over 30 feet to the lode. This company has a mill all ready to put up as soon as ore is found....Silver Glance tunnel is going forward at the rate of two feet each shift, in ore of low grade.... Rumor has it that the ore on the dump of the Morning Star, several hundred tons, has been purchased by parties who will ship it to London....The lower tunnel of the Schenectady is in harder rock, but it is thought a run of 20 feet will be made. ....The Pioneer mill has been running all the week, day shift, on Good Hope rock.

M. C. Tunnel No. 3.—The indications for finer ore were favorable yesterday. The Co. has run across a body of low grade ore, containing at least a half million tons, which will pay a profit with the improved appliances coming into use.

Leviathan.—The lower tunnel is run 25 feet a week, and a shift of men was on Monday put upon the croppings where the nice ore was struck. Prof. Rickard will finish the furnaces and be ready to fire up as soon as the materials can be hauled in.

Exchequer-Buckeye. — *Chronicle*, 23d: Work progressing finely. A shaft is being sunk preparatory to drifting in the 50-foot level. The next ore worked at the Stetefeldt furnace will show rich.

Mt. Bullion Co.—Operations suspended in the tunnel, but a shaft will be sunk on the Duke of Wellington,—the Co's main ledge.

AMADOR COUNTY.

Coney.—*Ledger*, April 30th: Work on this mine will be commenced as soon as the sale in bankruptcy is confirmed by the Commissioner.

Oneida.—Coal from a bed near Ione City will soon be used in the furnaces in place of wood.

BUTTE COUNTY.

Wyandotte.—Cor. of Oroville *Record*, April 30th: At Bidwell Bar mining is prosecuted with fair success. Madame Fitzgerald is working five hands on the "bluff claims," on the east bank of the Feather river. On the town side Mr. Marlow is working three hands, with fair profit. Bell & Co. are making a test of rock from the Bummer ledge, with their arastras. At Stringtown, Messrs. Mooney, Crandall, Tobin, Woodman, and others, are taking out enough to look cheerful. Mr. Slater's quartz mill has ceased to run, however, and times are dull in consequence. At Wyandotte, mining is as lively as ever.

CALAVERAS COUNTY

Rich.—*Chronicle*, 30th: On Tuesday, A. M. Harris, of the Woodhouse mine, Sandy gulch, brought to town the largest amount of amalgam we ever saw at one clean-up; not less than eight or ten thousand dollars. The rock was from the old Woodhouse claim, near the surface.

Big Yield.—Two tons of quartz from the mine of Cudell, Sanderson & Gay, near Railroad Flat, worked in the Thoss mill at West Point $76.50 per ton.

Railroad Flat.—Cor. of same: The Petticoat mill has been running steadily for three weeks. Mr. A. F. Burr is entering upon operations in the vicinity, having negotiated for the Hepburn quartz mill, which is being reconstructed and will be run by steam. A splendid engine has been purchased. The placer mines have not yet complained of scarcity of water, and, judging by the looks of Mr. Clark's ditch, I think it will be some time before they will.

EL DORADO COUNTY.

Rich Strike.—Placerville *Democrat*, April 30th: Stuckslager & Co. struck a rich vein of what appears to be decomposed sulphurets, in their claim near Uniontown, a few days since. They have already taken out several hundred dollars.

KERN COUNTY.

Los Angeles telegram, April 29th: Work on the Joe Walker mine has been resumed. The indications are good. Five large teams, with machinery for pumping out the mine, have made the crossing of Kern river at the Bakersfield ferry.

LOS ANGELES COUNTY.

Soledad.—Los Angeles telegram of 27th: A new mine, owned by Don Andreas Pico and others, develops a ledge two and a half feet wide; the rock is now paying $52.50 to the ton. A gold brick of 53 ounces, the clean-up of 16 tons of surface rock, was received to-day.

MARIPOSA COUNTY.

The Estate.—*Gazette*, 29th: In March the gold yield of the Mariposa Estates was $21,230, and in the first 14 days of the present month, at the Benton mills, the sum of $10,000 was turned out.

NEVADA COUNTY.

Deer Creek.—*Transcript*, April. 29th: A large number of men are at work along the channel. The claims are mostly owned by white men, who lease them to Chinese companies. On the creek there are probably 150 Chinese employed on claims, which, were it not for them, would remain idle.

At Little York things are lively.

At Eureka, three quartz mills are running, and prospects are fine.

At Quaker Hill, Jacobs & Co. have been working steadily with plenty of water.

Cement Hill.—Same of 30th: The New York, Mount Pleasant, North Star and Hawkeye claims have been purchased by a company recently organized. The Co. propose to put on the best modern appliances for hydraulic mining.

Spring Slide.—Same of May 1st: This gravel claim is on Cold Spring cañon. Last year they expended $5,000 in prospecting, and during the last two weeks they washed gravel which paid six dollars per day to the man. The company is to put up mining and hoisting works.

The Eureka Mine.—Grass Valley *Union*, April 27th: Yesterday was the regular semi-monthly melting day. The bricks cast were worth $29,800, and came from 12 days' run of the mill and mine, including sulphurets worked within the time.

Allison Ranch.—Same of May 1st: The miners are down 600 feet below the ground on which the old company worked. They are preparing to sink for a new level. In the present drift the ledge looks well both north and south of the shaft. During the last week or two, the mill, with 12 stamps, has crushed 22 tons of rock for each 24 hours. On Friday rock was being put through worth $60 per ton.

Bright.—This mine, near the Colfax road, has a crushing of 43 tons of rock at mill, giving a yield of about $30 per ton. The ledge has been worked as far as possible without steam, and Driscoll & Co., the owners, are negotiating for machinery.

Norambague.—The tunnel, 1,100 feet in, cuts the ledge at a depth of 250 feet. A crushing of 100 tons of the rock is to be put through mill, in the course of three weeks.

Gen. Grant.—A crushing will be put through at Perrin's mill next week. Only 30 feet depth has yet been reached, but indications are good.

Perrin's Mine.—Down 370 feet on the incline. The ledge is very flat. Forty men underground keep the mill supplied with rock. The mill has 10 stamps, and is capable of crushing 20 tons per day of rock from the Grant. A large water-wheel runs everything. A clean-up of the plates below the batteries last week gave $18,75 per ton, and the gold in the batteries will largely increase the figures.

Banner Mine. — *Gazette*, April 27th: Twenty of the forty stamps now run night and day. The rock averages $23 per ton.

Shanghai Mine.—Same of 28th: A lot of rock, just crushed, paid $56 per ton. The mine had been idle for some time.

Greenhorn.—They have a ledge five to seven feet in width, reached by a tunnel 200 feet long. It only costs $1.50 to get out a ton of rock and convey it to the mill. The mill has eight stamps and is kept humping itself. The rock averages $22 per ton, exclusive of sulphurets, which are worth $90.

Wigham Mine.—Fifteen tons sulphurets saved every month, worth $75 per ton. Shaft now down 520 feet. The rock averages $35 per ton.

PLACER COUNTY.

Mining Items.—*Stars and Stripes*, April 28th: The Mallet mine, owned by W. G Green, and others, has yielded 154 ounces of gold within the last two weeks, worth $16 per ounce. The Good Friday is again paying handsomely, It is estimated that the rock taken from the St. Patrick mine, on Saturday, will yield $1,000. A. O. Bell took out $1,000 from his mine last week.

St. Patrick Mine.—*Herald*, 30th: On Saturday the workmen reached rich rock, which has been growing richer and richer, until on Thursday the whole width of the ledge, twenty inches, for the full length of the shaft showed surpassingly rich rock. We are told by a good judge who visited the mine on Tuesday that there was a quantity of ore out that would pay fully $6,000 to the ton. There is now at the surface 20 tons of ore, not including the richer specimens, which will mill at least $8,000, and the richest ore yet seen is now at the bottom of the shaft.

Ophir.—Cor. of same: The Empire mill has enough quartz engaged to keep running for the next month. Staples & Co. are going to repair their mill. Chas. Pugh is refitting his old mill. The Indian Mound Co. are taking out better quartz than at any time since the discovery of the ledge. George Clark & Co. are taking out very rich quartz opposite Staples & Co's mill. A company of miners from Grass Valley made a purchase of the Hunter ledge lately, and are getting good rock. Wm. Green has taken out several thousand dollars within the last ten days. The St. Patrick is turning out gold by the pound. Since last Friday they have realized $3,000 or $4,000 in specimens. Mr. Eaton has already taken out more than he paid for the claim and all labor on it. McLaughlin has leased the Doeig ledge from Mr. Schnabel. It is near the St. Patrick. Several years ago the owners realized over $90,000 by the hand mortar process. The owners of the Peter Walter start up again about the first of May. Peter took out of this claim before he sold $30,000. The present owners intend to sink the shaft to the depth of 100 feet, and run levels, east and west. The Buckeye, near the Peter Walter, on Humbug flat, has a shaft 140 feet deep. This claim will be in operation in a short time. The Old mine, on Crater hill, owned by Spear & Lyon, will be moving along with the tide of prospecting next week. Reed & Browse, at the time they worked the vein, took out $60,000, and it was only partially worked to the depth of 65 feet, with gold in sight in the bottom level. Sweney & Puffer have realized $2,340 on their last crushing of 156 tons.

SISKIYOU COUNTY.

Quartz Mill.—Yreka *Union*, April 29th: The owners of the Norfolk and Lodi ledges, near Cottonwood, have made arrangements to have A. M. Jones, of Humbug, remove his mill, and put it up near said ledges, for the purpose of prospecting the quartz.

STANISLAUS COUNTY.

The Mines.—Tuolumne City *News*, April 29: The last heard from the party opening out what is called the "Lost claim" was, that they had not reached the bottom of the old shaft. We have just been shown returns from an assay of rock taken from the Nut Pine district, which has proven rich, both in gold and silver.

TRINITY COUNTY.

Keno Flat.—*Journal*, April 30th: Two day's washing last week paid ninety dollars.

Dutton Creek.—The boys expect to begin sluicing next week.

YUBA COUNTY.

Big Blast.—Telegram, April 26th: A large blast was exploded in the old Peterson claim, at Sucker Flat, Yuba county. Eight hundred kegs of powder, weighing 14,000 pounds, were fired at 2 p. m. to-day. The blast was a perfect success.

Arizona.

Walker District.—Prescott *Miner*, April 16th: Eureka 10-stamp mill was running, and Mr. Tiernan was testing the sulphurets. Uncle Billy Pointer had cleaned up his arastras, after working 8½ tons of ore, which paid $40 to the ton. Work upon the Accidental tunnel was progressing....C. Y. Shelton and others were taking ore from their ledges....The placer miners were making small wages. The water was failing rapidly. On Lower Lynx creek, the placer miners have been doing first rate. Jackson, Lovejoy & Co. took out, in five days, with three hands, eighteen ounces of dust, worth $18 per ounce.

Big Bug.—A miner who came over a few days ago, said the mill was running. Rich rock had been struck at the bottom of the 80-feet shaft, so rich that the gold was discernible in it by candle-light.

Hassayampa.—We learn that a clean-up was recently made at the Sterling. Owing to the scarcity of water, not many tons of ore were crushed. Mr. Beseler is working the sulphurets.

Martinez.—Messrs. Fine, Morgan, McAteer, Henry and others arrived here Thursday from this new district. Parties had commenced work on the Martinez lode. The Mayflower, a new lode, is said to be very rich.

Wickenburg.—It is rumored that very rich ore, and water, have been struck at the bottom of the deep shaft in the Vulture mine. The ore, it is said, will pay $1,000 to the ton....The owners of the White Picacho mine were confident of striking the vein this week, in their tunnel.

British Columbia.

The Victoria correspondent of the *Bulletin* writes, April 13th, that the news from the Peace River mines is anything but encouraging.

Idaho.

Bullion.—*Avalanche*, April 20th: Wells, Fargo & Co. shipped Wednesday to San Francisco ten bars Golden Chariot bullion, valued at $21,800, the product of 344 tons, an average yield of about $63.

Flint District.—Black's mill will start up Monday. There is rock ready for crushing from the Leviathan, Pioneer and other mines. Rising Star Co. will soon commence work.

Snake River Mines.—*Statesman*, April 26th: Placer mining is lively. Several hundred are engaged, and from eight to twenty-five dollars per day to the hand is taken out.

Montana.

Summit.—*Capital Times*, April 18th: The assay of the rock from the tunnel in the John How lode shows results varying from $2.50 to $74.50 per ton of gold.

Spring Gulch.—Same of 20th: This is distant from Virginia 15 miles. Prospects as high as $17 to the pan have been obtained in spots, but the drawback is want of water. Fourteen companies have started in at different times to bring in a ditch, seven and a half miles long, from Granite creek. Another company is now engaged on it who are determined to finish.

Madison County. — Same of 25th: Around Central, Nevada, Adobe Town, Junction, and down to the mouth of Alder, claim owners are hard at work. There is only one hindrance—a scarcity of men.

Fine Yield.—A gold retort, weighing 35 and 48-100 ounces, was the yield of nine tons of ore from the Golden Clipper lode, Silver Star, from a nine days' run on a small arastra.

Vawter Lode.—Helena *Gazette*, 25th: Fifty tons of the 350 taken out has been crushed, yielding $15 per ton. The tunnel is in 50 feet, and the vein is from 5 to 15 eet wide.

Philipsburg.—*Independent*, 23d: Horace Countryman made a large number of assays, all of which were flattering—the average from the Speckled Trout being $194 44. There is now ready for smelting four hundred tons of this ore. A smelter is being erected by Mr. Saunders. The shaft on the Speckled Trout is down 82 feet, and shows a body of ore four feet thick. Merrill & Co. are taking fine ore from the Van Timmens lode.

Prospects at Rocker City were never better. Several hundred men are wanted at from $5 to $6 per day.

Cable.—*New North-West*, 22d: Frazier, Carpenter, Hays, Aiken & Co. have their tunnel in 900 feet. It is so straight, newspapers can be read at the face of the tunnel about noon....Mr. Cameron expects to begin work on the 20th.

Silver Bow.—Cor. of same: Boitean, Burns & Co. and Burton & Sherman are putting flumes in Sage Brush gulch, and Gazzert, Lablin & Co. are fluming Conan flat and Pony gulch. Oakwood & Chime, in Pioneer, have their flume ready for water. The Pioneer & Rocker Ditch Co. are extending their ditch to cover Granite, Bully Boy, Bilk, Rabbit, Ready Cash, Star and Herring's gulches, also, Montana, Minnesota, Short, and Deep bars, and Harris' hill. All this ground has paid to haul to water in wagons, and will pay enormously to sluice. Ground is held at high figures. Wages are $6 per day, and men at present plenty, though if the water difficulty was settled there would be many more wanted.

Cedar Creek.—A. J. Simmons writes the Helena *Gazette* that the creek will be high and in many places unworkable, in the early part of the season, and many comers will be disappointed; although there are mines enough known to be paying to sustain several thousand miners when got in running shape.

Another correspondent of same says money will not be plenty until fall—for then only will the whole creek yield pay. Those who are at work are doing well. On Barrett's discovery claim, two days' sluicing, with two hands, yielded at the first run seven and a half ounces, and at the second, nine ounces of coarse gold. On No. 56 above discovery in the same district on Hugh O'Neil & Co's claim, one day's run gave $600. Claims are ranging from $1,200 to $5,000.

The *New North-West* has received the same figures from O'Neil's clean-up as are given above; but adds, that another informant says the said clean-up was only seven ounces.

New Mexico.

The Prospects.—*Press and Telegraph*, April 15th: These were never better. The miners are getting ready. The water supply will be more ample than for last year. This season there will be 60 stamps at work on quartz. Mr. Thomas Pollock on Saturday showed us seven ounces of gold, the result of the first three days' run in his claim at the mouth of Grouse Gulch. Carpenter & Lowthian are putting down 550 feet heavy galvanized 6-inch iron pipe in their claim.

The New Mines.—A correspondent of the *Alta* writes from Virginia district in conformation of the wonderful stories of the richness of the mines. The tradition of the "Lost Mine, and Cabin," is, he says, verified. "The cabin is of rock, 18 feet in diameter, and 4 to 6 feet in height, and in circular form, plastered in the inside with an opening some two feet square, and closed by two huge rocks; the covering consisted of cedar poles laid across and covered with dirt to the thickness of about one foot. At different places and in different ledges are found traces of ore having been removed. Several places on the Harpending, Brown, Idaho, Elias and other ledges furnish undeniable proof of the excavation of tons of rich sulphurets, such as would undoubtedly yield away up in the thousands; it is only when these gray sulphurets are found that any traces of work exist."

The Tucson *Arizonian* of April 9th confirms the stories, and says miners have commenced flowing into that place, and thence into the mountains south and east.

Nevada.

COPE DISTRICT.

Items.—Elko *Independent*, April 30th: C. F. Cutler will soon have mill running at Mountain City....Dyer & Walker received yesterday 150 ounces of gold dust from Cope. Among this was a nugget worth $126. The proceeds of the placers amount, it is said, to $500 per day....The Tucker boys are at work in Bull Run taking out ore to be sent below for milling. A large shipment will arrive from the Porter mine....Reinhart, Drew & Co's mill, at Mountain City, started up Wednesday on Argente ore. The mine owners have contracted to furnish 1,500 tons.

Bruno District.—In all instances where work has been done, the ledges improve in size and quality. The placers are paying well.

HUMBOLDT.

Golconda.—*Register*, April 30th: San Francisco parties are to erect smelting works for the Gold Run mine. Millions of tons of $30-ore can be had in this county at a depth of less than 10 feet.

Bald Mountain.—By letter we learn that extensive mines have been discovered.

Railroad District.—Cor. of *Independent*, 27th: Grant and Peak have sold their interests in the Broadhead mine to a Philadelphia party. The deed calls for $5,000. Mr. Franks is developing the Tycoon. It shows a body of ore 10 feet wide. Whitefield and Witham are turning out ore from the Lone mine. It proves argentiferous lead, containing $80 per ton in gold and silver. Grant & Co. are opening the Rhino, a galena mine, with splendid prospects. Brown, Paxton & Co. are raising ore from their copper mines, the Manhattan, Brown and Richmond. Uncle Fowler is sacking ore from the Bunker Hill. Uncle Sutton proposes to build a smelting furnace immediately. Prospecting continues. Several promising galena and copper veins have been discovered within a few days.

Unionville.—John C. Fall shipped 358 pounds of fine bullion from his mill during the week ending Monday.

REESE RIVER.

Mineral Hill.—*Independent*, April, 30th: The Ward and Spencer Co. has put on night shifts. Shipley turned out 5,000 bricks in five days' work for the new mill.

The Grass Valley *Union* has the following from J. C. King, recently returned from Mineral Hill: Four men, D. Macdonald, D. K. Northy, John Sheehee and James F. Ward, have 41 locations of from 600 to 1,000 feet each, and have opened 21 of them into the hill by running cuts. These cuts are all in mineral. This Co. have now on hand and in sacks 600 tons of ore, and are making preparations to build a mill. They have sent off and have worked 100 tons of ore, and the returns were $503.45 per ton.

WASHOE.

Yellow Jacket.—Gold Hill *News*, April 30th: Daily yield 300 tons. The ore at the 900-foot level has not been looking so well, owing to an extensive "horse."

Hale & Norcross.—Daily yield 150 tons, the principal supply being from the sixth level, and the assays show an improvement in the general character of the ore. The seventh level already gives a yield of 60 tons per day.

Virginia Consolidated.—The drift west at the 500-foot level is in 300 feet. The rock works favorably. Some good ore was developed in the upper workings Tuesday, 200 feet from the surface. Assays from it range above $500 to the ton.

Overman.—Yielding 100 tons daily. In the old Mary Ann chimney, some good ore is found, and the general yield shows improvement.

Hope.—The mine at Silver City is y - ing well. The new mill is completed, and started ten stamps Monday.

Occidental.—The lower tunnel is being driven ahead to effect the connection with the winze from the old mine above. This will take six weeks.

Ophir.—Thirty tons daily extracted from the old upper mine through the south shaft. None yet through the north.

Gould & Curry.—Daily yield 90 tons; assays $52 per ton.

Imperial-Empire.—Drifting west at the 1,200-foot station commenced. Sinking the shaft progresses well, considering the nature of the rock.

Belcher.—The ore streak in the 730-foot level has not turned out as good as anticipated. It is now proposed to raise upon it. The upper levels continue yielding 80 tons of $20-ore daily.

Chollar-Potosi.—Daily yield 100 tons, from the upper levels; average assays, $73 per ton. The dumps are all full and the mills well supplied.

Sierra Nevada.—Assays indicate an improvement in the ore passing through the mill.

Sacramento & Meredith.—The mill will shortly be ready to commence reducing ore,

Crown Point.—Incline 67 feet below the 1,000-foot station. Upper levels yielding 70 tons per day of low-grade ore.

Sutro Tunnel.—*Enterprise*, May 1st: An increased force of workmen are employed. The work progresses finely. The tunnel is in 1,000 feet. The ground is improving for blasting.

WHITE PINE.

Review.—*News*: A large number of base metal mines, heretofore idle, have been started up, and the district has a busy and prosperous appearance. Bullion shipments for the week ending April 25th foot up $17,162.25 to San Francisco, $12,281.21 to New York—total, $29,443.26—and 48,790 pounds of base bullion. Outside districts are attracting the attention of Eastern capitalists to an unusual extent. Pinto district made a sale, a few days since, for $25,000. Eureka has made a heavy sale to English capitalists, while Chicago is investing largely in Freiberg and Philadelphia in Silver Peak. Silver Park is now the most flourishing camp in Eastern Nevada; its two mills running; all the mines opening well, and new and rich discoveries being daily made. Shoshone sends in good reports and a considerable quantity of ore. Robinson district is commencing work on an extensive scale. Ely is languishing and waiting for freight, now en route. New York is investing largely in Reveille.

Items.—*News*: Secret Cañon ores tested so far yield on the average $500 to the ton. ....A new furnace near Swansea is nearly ready to fire up....Chicago manufacturers talk of erecting another separating establishment here, and engaging in the bullion trade....Shaft on the Elko mine is down 70 feet in a 7 foot vein....Frederick Voss now own the Shermantown smelting works. ....The Alsop works have turned out 170 tons bullion during the present run, and the furnace lining is still good....Native copper is now met with in Crown Point No. 8, and no lead is found. Between the two was a stratum of chloride of silver.... Eberhardt is looking better than a year ago. The lower tunnel shows the continuance of the rich deposit to a great depth. ....Eureka is meeting with very rich ore. ....The thousand pounds of Trench ore yielded $1,900 pounds of bullion which gave $1,500 in silver. This is a base metal mine.

Utah.

The Corinne *Reporter* of April 23d says that a party of prospectors from Odgen have developed a ledge of silver ore that is likely to exceed in richness anything ever before seen in Utah or Nevada. This discovery was made eight miles northeast of this city. The names of the discoverers are R. S. Beebe and George H. Bemis. Mr. Bemis informs us that an assay of the ore showed silver $400 to the ton.

The American Mills on California street are worked under renewed auspices. Mr. D. Boyle has bought out Mr. W. C. Benn's share, and thus enters into active partnership. Drugs and spices, besides grains of all kinds, are ground here, and the utmost attention paid to customers' desires.

San Francisco Mining Stock Market.

The interruption to the business of the Board by an adjournment on Monday last for that day, seems to have imparted more activity to operations, and considerable improvement is noticeable throughout the general list since then.

Hale & Norcross—has been rather dull of sale, at uniform rates. On the 1st inst., $24,723 in bullion was forwarded to the office in this city. At the above date, the winze had attained a depth of 76 feet below the sixth level, the ore being still of a good quality. They expect to connect this winze with the north drift from the seventh level in the latter part of the week. On the seventh level, the north drift is now 62 feet north of the shaft. The east cross-cut is now 32 feet east of this north drift, and they have not yet reached the east wall. North of this cross-cut, and east of the north drift, they have blasted out a chamber of ore 25 feet wide, 35 feet long, and 10 feet high, all the ore taken from this space being of good quality, and the vein, at this depth, is reported to exhibit evidence of permanence and extent. For the week closing April 30th, 319 tons of ore were taken from the upper mine, and 753¼ from the lower, making a total of 1,072¼ tons. In the dumps, they have 6,806¼ tons. A dividend of $7 60 per share will be disbursed on the 10th inst.

Overman—has been in the market to a moderate extent, at an advance. On the 2d inst., crude bullion estimated to be worth $35,000, was sent forward to the office in this city. During the week ending May 1st, they extracted 1,027 tons of ore. The body of ore on the 226 level, south, has the appearance of pitching down, and they have commenced running south on the lower levels, with the expectation of cutting this body of ore.

Chollar-Potosi—has been in the market to a larger extent than during the previous week, commanding increased rates. They extracted 1,022 tons of ore during the week ending April 29th, against 1,300 tons the previous week. The Blue Wing stope is looking quite as well as it did a week ago. At the new shaft, the north drift reached a heavy body of clay, and work has been suspended at this point until the clay stops swelling. The ore-slip of the 2d inst. shows that they sent 241 tons to five different mills on that day. This company will disburse a dividend of $1 per share on the 10th inst.

Imperial—has been less active, showing an improvement over opening rates. On the 3d inst., the southwest drift was still in white quartz. The "raise" from the 1,084 level is showing the ore much narrower as they go southward, and on the north line it has entirely cut out. The 1,200 station is in about sixteen feet.

Segregated Belcher—was inquired for to a limited extent. On the 3d inst., $11,397 80 in bullion was forwarded to the office in this city. The rock pays better than they expected, yielding a larger percentage of gold. They take out about thirty tons per day.——Belcher has been well maintained. On the 30th of April, $10,418 in bullion was shipped here. The 730 level is said to look more favorable, yielding better quartz.——Ophir was quite largely dealt in toward the close, under a slight recession. The north-west branch of the Walsh Tunnel is in a reddish quartz, and is reported to look somewhat more favorable, otherwise no change.

Sierra Nevada—sold to a moderate extent. The ore product for the week ending April 30th, amounted to 1,754 tons, 1,718 tons coming from the gravel deposit and 36 tons from the ledge.——Savage sold to a large extent toward the close, advancing to $37 per share. An assessment of $7 50 per share was levied on the 3d inst. ——Eureka (Cal.) will disburse a dividend of $7 50 per share on the 7th inst.——North Star (Cal.) is again paying dividends, having announced one of $1 per share for the present month.—*Commercial Herald.*

San Francisco Prices of Copper Ores.

San Francisco, May 5, 1870.

W. T. Atwood states the following as approximate price at which copper ores can now be sold in this city. There is no sale for ores which assay less than 10 per cent.:

	Per ton.		Per ton
12 per cent. ore	$24 00	18 per cent. ore	$41 40
13 " "	26 65	19 " "	44 65
14 " "	29 40	20 " "	48 00
15 " "	32 25	25 " "	62 50
16 " "	35 20	30 " "	75 00
17 " "	38 25		

Ores assaying above 30 per cent., $2.50 per unit. Bars at the rate of 13c. per lb. for pure copper.

◆

Patents on the Pacific Coast.—To those of our friends who desire to keep posted upon inventions upon the Pacific coast we say, subscribe for the Scientific Press, published by Dewey & Co., San Francisco, Cal., at $4 per year. The opening of the railway across the continent has given to all patents a much higher value in that portion of our country known as the Pacific slope, and all interested will find the paper above alluded to a valuable reference.—*Mechanic and Inventor, Detroit, Michigan.*

The Richmond Disaster.—On the 28th ult., when the court room of the State Court of Appeals was crowded to hear the decision with regard to the contested mayorship, the gallery gave way and precipitated the spectators to the main floor. This in turn fell through, and sixty souls were launched into eternity. Many of them evidently died from suffocation, as their bodies showed no external wounds. Besides these a large number were seriously injured. The fire alarm was sounded, and the fire companies, aided by citizens, repaired to the rescue and the bodies were removed from the ruins. The stores in the city closed and the news carried sorrow everywhere. Some of the most prominent citizens of Richmond were killed, and expressions of sympathy have been sent with offers of pecuniary aid to the families of the victims from many eastern cities. Was the builder of the edifice responsible for this disaster?

◆

Mr. J. S. Hunt, whose advertisement will be found in another column, has shown us some mantles, which were so like real marble that every one would consider them such. They are of the handsomest appearance, and being comparatively very cheap, as they are marbleized slate, and form an exceedingly lasting article, are being used extensively at the East in the finest residences. Persons intending to build should examine the samples which Mr. Hunt has on hand.

◆

Hudson & Menet's Annual for 1870 is a valuable publication for business men everywhere. It gives the name of every State and county in the United States, and nearly all the cities of any note; also, every paper and periodical published, so far as obtainable, with the name of the publisher and locality of the publication. Messrs. H. & M. are General Advertising Agents, at No. 41 Park Row, New York City.

◆

Mechanics, stair-builders and workers in wood will find it profitable and interesting to visit the shop of H. G. Stilley, whose advertisement may be found in another column. Mr. Stilley has a reputation for superior workmanship, and for fidelity in executing orders. We believe that he is the only plane-maker in the city. Stair-builder's routers of every description are made, and every variety of moulding tools repaired.

Farming and Gardening.

Communications for this department are solicited from all parts of the Pacific States and Territories.

Century Plants About to Bloom.

The Oakland *News* says that a century plant *(Agave Americana)*, in the garden of General Kirkham, on Oak street, in that city, is about coming into bloom. The plant has already spread its leaves to a diameter of sixteen feet, and is ten feet in height. From its great size and present indications, it is thought the flower stem may reach the very unusual height of forty feet. Our Eastern visitors, the present summer, who may be here when the plant is in bloom, will thus have an opportunity of inspecting a specimen the most magnificent floral curiosity in the vegetable kingdom.

We notice by the Stockton papers that there is also a century plant in that city, which it is expected will bloom the present season. As there are now a great number of these plants scattered throughout the central portions of the State, it will be but a few years before their presentation of bloom will become an ordinary affair, exciting very little interest except from strangers. The period required for these plants to come into bloom varies with the climate in which they are grown. Under favorable conditions, as in Mexico, where they are indigenous, they often bloom in ten years from the time of planting. Their period of blooming in this State varies from fifteen to twenty years. In the Northeastern Atlantic States, where they have to be kept in hot-houses the greater part of the time, that period varies from 70 to 100 years—hence the name of century plant. The plant never blooms but once. After blooming and perfecting its seeds, it drops them naturally to the ground, where they take root; while the parent plant, having fulfilled its mission, gradually withers and dies; thus returning its substance to the earth to feed and nourish its successors.

The English Wheat Market.—Accounts from Europe still report large importations of grain from the Baltic provinces of Russia to Liverpool, with the intimation that arrivals from that quarter will probably be kept up to an extent sufficient to continue the present depressed state of the wheat market in that city.

This intelligence has already exerted such an influence on the wheat-growers of the Mississippi States as to induce the farmers there to greatly reduce their breadth of this cereal. Many will reduce their wheat one-half and double their corn, converting the latter into pork. The increased railroad facilities in Europe, whereby the great granaries of that continent may be more easily reached, will soon destroy the European market for American breadstuffs, and force our farmers into the necessity of other cultivation, or an increase of our manufacturing interests, in order to provide a home market for our cereals. California farmers will do well to make a note of this, and turn their attention more generally to other crops than wheat. There is no need that we should continue to raise wheat at a small margin or no margin at all for profit, so long as we import from other States more than half of our butter, cheese, beef, pork, etc. We are also importing fibers of jute, flax, wool, cotton and silk to an amount exceeding our present wheat exportations, all of which ought to be produced on our own soil.

Artificial Incubation.—A gentleman near Alameda has now in process of incubation 700 hens' eggs, from which he expects to realize an equal number of chickens, with the aid of artificial heat generated by an ordinary coal-oil lamp. The eggs are placed on shelves, in an air-tight box, and the hatching process can be easily heard by an attentive listener.

Tropical Fruits in California.

It is encouraging to witness the rapid increase in the production of tropical and semi-tropical fruits in this State. The central and southern portions of California are capable of producing all the oranges, lemons, limes, olives, and all other species of semi-tropical fruits required to supply the wants of all the States in the Union. Great profits have already been realized from this branch of fruit-growing, in simply supplying the market of this city. The time is not far distant when such fruits, grown in this State, will find a large market, *via* the Pacific Railroad, all through the interior portion of the continent and the present "Western" States of the Union. Grapes, English walnuts, figs, raisins, almonds, etc., should also be added to the list.

Orange trees, in this State, bear all the year round. Ripe oranges and orange blossoms may be picked from the same tree nearly every month in the year.

The orange is a comparatively hardy tree, long-lived and a great bearer. One orange grove, owned by B. D. Wilson, at the Lake Vineyard, Los Angeles county, consists of 600 trees in bearing, which last year produced an average of 1,200 oranges each, which were sold for an aggregate of $21,000. This grove covers ten acres of land. The trees are young and not yet in full bearing. At the Mission San Gabriel, in the same county, there are thirty trees, sixty years old, which average about 3,000 each. There is a single tree at this Mission, eighty years old, 5½ feet in circumference, which last year produced 5,000 oranges! On the Wolfskill ranch, also in Los Angeles county, is a grove covering eight acres, from the product of which there was, last year, realized $14,000. The oranges, lemons and limes of Los Angeles are mostly natural fruit, and commence bearing at from six to seven years of age. At ten years they will generally average from 1,000 to 1,500 oranges each, worth, on the ground, generally about $2 per hundred.

Olives make a fine growth in almost all parts of the State, and, like other fruit, are generally raised without irrigation—in fact, the best specimens are thus raised. Trees, four years from the cutting, will measure seven inches in circumference.

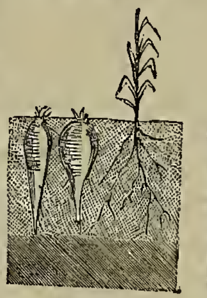
The same may be said of the almond. There is an almond tree in the door-yard of Mr. Furbush, at Santa Barbara, only thirteen years old, which measures forty inches in circumference, three feet above the ground. For the last three years it has borne an average of eighty pounds of almonds, worth from $35 to $40. It was set out merely for a shade—quite a valuable shade tree! Messrs. Ferrold, Blanchard & Towle, in the same place, have for some time had 500 almond trees in bearing; next year their number of bearing almond trees will be increased to 2,500. There are many other almond orchards in the same vicinity and in other parts of the State. The almond of California is not excelled by that produced in any other part of the world.

It would probably take this State fifty years to put itself in a condition to supply the full demand of the United States with the tropical and semi-tropical fruits which our present and rapidly-increasing wants will demand, even if our fruit-growers were to make special and general efforts in that direction. That our people are not altogether idle or lacking in consideration in this matter, may be inferred from the present rapid increase in the number of such trees which are being set out in all parts of the central and southern portions of the State. From the Agricultural Report of 1868 we have the number of a few of the trees alluded to which were then growing in the State, as follows: Orange trees, 17,281; lemon, 3,712; olive, 14,838; prune, 6,527; almond, 25,319; walnut, 15,614; fig, 33,924,—total, 116,471.

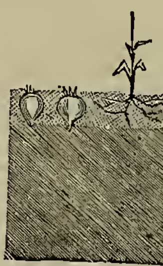
By the report of 1869 it appears that the number had increased to the following figures: Orange, 30,569; lemon, 5,280; olive, 19,946; prune, 8,569; almond, 32,400; walnut, 22,888; fig, 40,819,—total, 162,471; or an increase of 39 per cent. in a single year. The activity manifested in that direction, the present year, warrants us in saying that the report for 1870 will show a still larger percentage.

Agriculture for California—Practical Views.

We would call the reader's special attention to an article in another column, under the above head. The writer is evidently a man of intelligence and practical experience. His views with regard to the system of culture applicable to a large portion of the farming land of this State, are correct, and in full accordance with the opinions often expressed in the columns of the Scientific Press. Indeed we reproduce, in connection herewith, a small figure employed a few weeks since to illustrate the same views in one of our own articles. We do not know how we could better illustrate the experiment reported by the correspondent of the *Bulletin*, than by the two figures herewith presented. If the roots of a plant are kept near the surface, by shallow plowing, they *must* suffer when drouth comes; on the contrary, if we plow or "dig" deep and loosen the soil so that the roots can easily go downwards for moisture, instead of running off at right angles in a vain search therefor, in the dry and shallow bed to which they are necessarily confined by shallow culture, a healthy and vigorous growth will be the result, both above and below ground, as represented above. Pulverize the soil then, and let the roots go down, as they will, to where moisture always exists, in all cultivated soil. Such a course, in most cases, is far preferable to, besides being much cheaper than, surface irrigation.



Deep Tillage.



Shallow Tillage.

We are pleased to add the benefit of our circulation to that of the *Bulletin* in giving publicity to the views and facts therein stated. True, they should "be applied with proper discrimination with reference to local peculiarities of soil and climate;" but actual experience is what is wanted, and the success or failure of an intelligent cultivation is always the surest guide to others.

Successful Tree Planting.—We mentioned, four or five months ago, that Mr. Tuttle, of Grass Valley, had brought from Missouri a quantity of tree seeds, and had distributed them freely among the people here. The consequence of that public-spirited enterprise, says the *Union* of that place, is, that Grass Valley has numerous varieties of the oak not indigenous to the soil, black walnut, persimmon, hawthorne, and other trees, starting into vigorous life, with every appearance of a determination to be successful. A little more attention to such things will make this coast prosperous, despite the wastefulness which has been committed.

It is proposed to form a Wine Growers' Association in the county of Amador for the advancement of the interests of those engaged in the cultivation of the grape. Amador might undoubtedly be made one of the best grape-growing counties in the State.

A Few Hints About Deep Tillage.

When the soil is stirred very deep, especially for grain, it should be done long enough before sowing to attain a sufficient compactness, at its lower portion, to favor the production of a multiplicity of small fibrous roots, rather than a few large ones. An open, porous soil, not sufficiently pulverized, favors the formation of large roots, and does not admit of the very ready ascent of moisture from below.

In plowing, especially in adobe soils, the plow should run no deeper than the soil can be thoroughly pulverized. It is better to plow five inches deep, with thorough pulverization, than ten or twelve where the furrow-slice at the bottom is merely turned over and not thoroughly broken up. An open and porous lower strata causes the soil to dry down to the bottom of the furrow, in consequence of the capillary attraction of the soil being destroyed; while if it was thoroughly pulverized throughout its entire depth, capillary attraction would be constantly at work bringing up moisture from the subsoil to the roots of the plant. The unfavorable results so often reported from deep plowing in adobe soil, may, in all probability, be universally attributed to the fact here stated. The best pulverizer for the soil yet invented is the Standish steam plow. It will be worth millions to California if that plow can be made a practical success.

Fluids will rise, by attraction, higher and more readily in small tubes than in large ones; and just in proportion as the soil possesses an infinitessimal number of small tubes or pores, over large ones, so is its power to draw up moisture from below or receive it from the moist atmosphere above. Deep plowing is worse than useless on dry soils, unless attended by thorough pulverization.

In deep plowing, care should be taken not to mix any considerable quantity of subsoil with the loam. The subsoil in most cases may be stirred and loosened up to advantage, but not brought to the surface to any extent. As a general thing, Nature should be followed in promoting vegetable productions. The subsoil should remain where it belongs naturally; it is thus in its proper place and fitted to do its proper work. Don't reverse the order of Nature.

Many turn up the subsoil with the view of thus mixing with the loam some of the salts necessary for plant food, which have been carried downward by the leaching action of rains. The practice is bad; more detriment than benefit is likely to occur therefrom.

It is true that all soils lose more or less of their essential salts by the leaching process produced by rain; but the best way to recover such salts is to loosen up the subsoil by itself, and let the rootlets of the plants go down after them. They will do it if you give them anything like a fair chance.

The practice of digging holes for the reception of trees far below the surface into the subsoil, and filling up the same with loam and vegetable refuse, is rather to be avoided, for several reasons. Such holes, especially in heavy clay soils, are apt to become huge flower pots, without the usual facilities for drainage. The water in them becomes stagnant and unfit for nourishing the tree. Again, as soon as the lower roots have extended beyond the "filling in," and into the side-walls, which they will do by the second or third year, the change in the soil is so sudden and marked as oftentimes to affect the roots very injuriously.

The surface soil for such planting, when shallow, may be made a little deeper than it naturally exists, and the subsoil may be loosened to a considerable depth and breadth. It may be shovelled out and thrown in again, with a very little loam mixed with it. The walls of the opening should not be made with a clean, smooth cut, as in sinking a well. Let them be jagged and irregular, so that the roots as they grow out into them may not be subjected to any very sudden change in the soil.

Importance of the Poultry Business.

Few persons are aware of the immense importance of the poultry business of this and other countries. New York City, alone, takes annually not less than four million dollars' worth of poultry and eggs; Boston consumes over two million dollars' worth, while Cincinnati annually buys from the neighboring country and sends away, after satisfying her own appetite, twenty-five million eggs alone, which, at only twelve cents per dozen, amounts to $250,000. The total consumption of poultry and eggs throughout the country must largely exceed $100,000,000, or more than three times the annual production of gold and silver on the Pacific coast!

John Bull also has a taste for good things, other than beef; as the single city of London receives not less than $12,000,000 in annual value of eggs alone, from Ireland, Belgium and France, aside from what that big city can gobble up from its own surroundings. Johnny Crapeau, too, does not depend alone upon soup and frogs for luxuries; as the statistics show that France, after sending out less than six million dollars in value of eggs to London, reserves for her own consumption over $200,000,000, of which amount Paris alone takes $10,000,000.

From these facts it will be seen that the consumption of eggs is vastly larger, in proportion to population in England and France, than it is in the United States—in fact, France probably consumes three times as many eggs, in proportion to her population, as do the people of the United States.

The poultry statistics of California are very meagre. We have never seen any estimate of the amount of eggs produced or consumed. The number of chickens in the State was set down in the Assessor's returns for 1868 at 1,450,069; but by the returns of 1869, they appear to have fallen off to 913,318; turkeys in 1868, 157,228; in 1869, 140,052; geese in '68, 25,537; in '69, 34,114; ducks in '68, 81,289; in '69, 63,046. It is difficult to account for the large falling off in 1969; so difficult, in fact, that we prefer to consider the report incorrect.

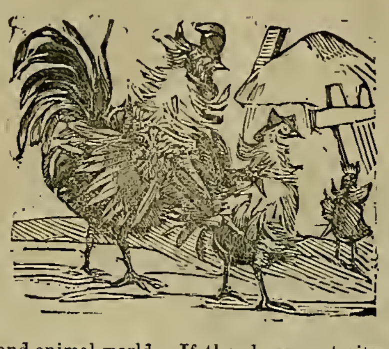
Quite too little attention is evidently paid to the poultry business in California, for, notwithstanding the enormously high prices paid here for eggs and poultry, immense amounts of the former, especially, are shipped to this city from Oregon, and shipments have also been made from Chicago. Turkeys have even been driven from the Southwestern States across the plains to this State. Were it not for the excessive rates of transportation and jobbers' commissions, eggs and poultry might be retailed in this city at less prices than in New York or Boston. Food and land is cheaper here; while the greater advantages of our climate more than counterbalance the difference in the cost of labor.

There is no branch of rural economy more sure or profitable than this. Small as it may appear to some, the above figures abundantly show that it is no trifling concern. It not only produces an immense article of consumption and commerce, but it enlivens and beautifies every rural home. It is, moreover, a business which is in no danger of being overdone. The consumption, per capita, of our population, would undoubtedly be doubled by a reduction of the price to its lowest, reasonably remunerative figure. There is no reason why a dollar should be sent out of the State to purchase either eggs or any species of fowls, other than such as it might be desirable to introduce for their blood.

Too little attention, we fear, is paid to the breed of our poultry, also to the *care* of the stock. When the best breeds are kept, poultry cannot fail to pay in this State, if reasonable care is taken to give them a plenty of fresh water, gravel, lime, good clean food (not refuse grain), a reasonable supply of flesh, clean roosts and shelter. Of course, every poultry raiser knows that great numbers should not be kept in a single inclosure. The inclosures, moreover, should be separated by some little distance, so that the air of no one may be vitiated by the noxious gases from any adjoining inclosure. The most popular breeds are the Black Spanish, the crested or Poland, the Dominiques, Dorkings, the Shanghai and central Asiatic (Brama Pootra) varieties.

The Crisp-Feathered Fowl.

Dame Nature often cuts curious freaks in her canny work, both in the vegetable and animal world. If the above portraits, which we copy from the *Rural New-Yorker*, are from life, they surely exhibit one of her most funny freaks. They are a curiosity, to say the least of them; and are certainly the most demoralized looking pair of fowls whose features and pictures have ever been brought to our notice. They are called, by the correspondent of the *Rural*, the "crisp-feathered fowl," and the question is asked, whether they are in any way related to the French "frizzled fowl?" The *Rural* sees no difference; but judging from the portraits of the two, we should suppose there was quite a marked distinction. In the make of the frizzled fowl, Nature has evinced her caprice by simply turning a portion of the feathers along the back and some other parts of the body around, and making them point towards the head, while the tail-feathers, in both the cock and hen, are quite regular. In the portraits here presented the feathers appear to have been stuck upon the bird, in a gale of wind, pointing every and all ways. Our readers will no doubt be impressed with their novel appearance.



It is said that this breed of fowls does not possess any peculiar advantages over the common barnyard fowl. It is probably more interesting as a curiosity, than valuable for practical purposes.

Castor Oil Beans—Proposed New Oil Mill.—Mr. C. H. Hodges has planted some 200 acres of castor beans the present year, and twenty-one acres of black or Norway oats, on his ranch near Marysville. There are several other ranches in that neighborhood where the bean is being cultivated to a greater or less extent. Dr. McDaniels planted some 200 acres last year, and we presume he has not decreased the amount for the present year. There are some five or six hundred acres devoted to the cultivation of castor beans in Yuba and Sutter counties. We see it stated that the erection of a mill for expressing and manufacturing the oil is contemplated at Marysville. We believe that Dr. McDaniels has a small mill on his ranch, which has been in operation for several years.

Bananas in Florida.—The banana is making rapid growth in Florida. A correspondent of a New York paper, on a visit to that State says: "Once a day we go to see the growth of the bananas which are now fruiting. The largest planted last year is about twenty-seven feet high, the stalk ten inches in diameter. On warm days a leaf will grow between three and four inches. The buds are inclosed in a large purple sheath, Each day it deigns to open, one leaf of the sheath is cast off, and the fruit, with the flowers on its tip, appears. The fruit, unlike most other fruits, forms in the matrix." Equally good results will no doubt soon be realized from similar experiments recently undertaken in this State.

What I Know of Farming—No. 16.

Thorough Tillage.

My little, hilly, rocky farm teaches lessons of thoroughness which I would gladly impart to the boys of to-day who are destined to be the farmers of this last quarter of this century. I am sure they will find profit in farming better than their grandfathers did, and especially in putting their land into the best possible condition for effective tillage. There were stones in my fields varying in size from that of a brass kettle up to that of a hay-cock—some of them raising their heads above the surface, others burrowing just below it—which had been plowed around and over perhaps a hundred times, till I went at them with team and bar, or (where necessary) with drill and blast, turned or blew them out, and hauled them away, so that they will interfere with cultivation nevermore. I insist that this is a profitable operation—that a field which will not pay for such clearing should be planted with trees and thrown out of cultivation entirely. Dodging and skulking from rock to rock is hard upon team, plow, and plowman, and it can rarely pay. Land ribbed and spotted with fast rocks will pay if judiciously planted with timber—possibly if well set in fruit—but tilling it from year to year is a thankless task, and its owner may better work by the day for his neighbors than try to make his bread by such tillage.

So with fields soaked by springs or sodden with stagnant water. If you say you cannot afford to drain your wet land, I respond that you can still less afford to till it without draining. If you really cannot afford to fit it for cultivation, your next best course is to let it severely alone.

A poor man who has a rough, rugged, sterile farm, which he is unable to bring to its best possible condition at once, yet what he clings to and must live from, should resolve that, if life and health be spared him, he will reclaim one field each year until all that is not devoted to timber shall have been brought into high condition. When his summer harvest is over, and his fall crops have received their last cultivation, there will generally be from one to two autumn months which he can devote mainly to this work. Let him take hold of it with reasonable purpose to improve every available hour, not by running over the largest possible area, but by dealing with one field so thoroughly that it will need no more during a long lifetime. If it has stone that the plow will reach, dig them out; if it needs draining, drain it so thoroughly that it may hereafter be plowed in spring so soon as the frost leaves it; and now let soil and subsoil be so loosened and pulverized that roots may freely penetrate them to a depth of fifteen to twenty inches, finding nourishment all the way, with incitement to go further if ever failing moisture shall render this necessary Drouth habitually shortens our fall crops from ten to fifty per cent.; it is sure to injure us more gravely as our forests are swept away by ax and fire; and, while much may be done to mitigate its ravages by enriching the soil so as to give your crops an early start, and a rank, luxuriant growth, the farmer's chief reliance must still be a depth of soil adequate to withstand weeks of the fiercest sunshine.

I have considered what is urged as to the disposition of roots to run just beneath the surface, and it does not signify. Roots seek at once heat and moisture; if the moisture awaits them close to the surface, of course they mainly run there, because the heat is there greatest. If moisture fails there, they must descent to seek it, even at the cost of finding the heat inadequate—though heat increases and descends under the fervid suns which rob the surface of moisture. Make the soil rich and mellow ever so far down, and you need not fear that the roots will descend an inch lower than they should. *They* understand their business; it is *your* sagacity that may possibly prove deficient.

I suspect that the average farmer does far too little plowing—by which I mean, not that he plows too few acres, for he often plows to many, but that he should plow oftener as well as deeper and more thoroughly. I spent three or four of my boyish summers planting and tilling corn and potatoes on fields broken up just before they were planted, never cross-plowed, and of course tough and intractable throughout the season. The yield of corn was middling, considering the season. That of potatoes more than middling; yet, if those fields had been well plowed in the previous autumn, cross-plowed early in the spring, and thoroughly harrowed just before planting-time, I am confident that the yield would have been far greater, and the labor (save in harvesting) rather less—the cost of the fall plowing being overbalanced by the saving of half the time necessarily given to the planting and hoeing.

Fall plowing has this recommendation—it lightens labor at the business season, by transferring it to one of comparative dullness. I may have said that I consider him a good farmer who knows how to make a rainy day equally effective with one that is dry and fair; and, in the same spirit, I count him my master in this art who can make a day's work in autumn or winter save a day's work in spring or summer. Show me a farmer who has no land plowed when May opens, and is just waking up to a consciousness that his fences need mending and his trees want trimming, and I will guess that the sheriff will be after him before May comes round again.

There is no superstition in the belief that land is (or may be) enriched by fall plowing. The autumn gales are freighted with the more volatile elements of decaying vegetation. These, taken up wherever they are given off in excess, are wafted to and deposited in the soil best fitted for their reception. Regarded simply as a method of fertilizing, I do not say that fall plowing is the cheapest; I *do* say that any poor field, if well plowed in the fall, will be in better heart the next spring for what wind and rain will meantime have deposited thereon.

Frost, too, in any region where the ground freezes, especially where it freezes and thaws repeatedly, plays an important and beneficient part in aerating and pulverizing a freshly-plowed soil, especially one thrown up into ridges, so as to be most thoroughly exposed to the action of the more volatile elements. The farmer who has a good team may profitably keep the plow running in autumn until every rod that he means to till next season has been thoroughly pulverized.

In this section, our minute chequer-work of fences operates to obstruct and impede plowing. Our predecessors wished to clear their fields, at least superficially, of the loose, troublesome boulders of granite wherewith they were so thickly sown; they mistakenly fancied that they could lighten their own toil by sending their cattle to graze, browse and gnaw, wherever a crop was not actually on the ground; so they fenced their farms into patches of two or ten acres, and thought they had thereby increased their value! That was a sad miscalculation. Weeds, briars and bushes were sheltered and nourished by these walls; weasels, rats, and other destructive animals, found protection and impunity therein; a wide belt on either side was made useless or worse; while plowing was rendered laborious, difficult and inefficient, by the necessity of turning after every few hundred steps. We are growing slowly wiser, and burying a part of these walls, or building them into concrete barns or other useful structures; but they are still far too plentiful, and need to be dealt with more sternly. O squatter on a wide prairie, on the bleak plains, or in a broad Pacific valley, where wood must be hauled for miles and loose stones are rarely visible, thank God for the benignant dispensation which has precluded you from half spoiling your farm by a multiplicity of obstructing, deforming fences, and so left its soil free and open to be everywhere pervaded, loosened, permeated, by the renovating plow!—*Horace Greeley.*

A New Fertilizer.—Mr. De Yerg, of Poughkeepsie, N. Y., is manufacturing from the slag of iron or other smelting furnaces, a new fertilizer—a soluble phospho-silicate. It is well known that the most fertile soil in the world is formed from the *debris* of volcanic overflows. Such soil is simply a decomposed scoria, the process of decomposition having been going on for ages by atmospheric and other material agencies. In the manufacture of his phospho-silicates, Mr. De Yerg simply imitates this action of Nature by a more rapid disintegration and decomposition. At the suggestion of Professor Tilmen, of Albany, specimens of this fertilizer have been submitted to the notice of the American Farmers' Club at New York, which body has appointed a competent committee to examine and report upon the same.

Candles may be made to burn their own wicks, by saturating them with a strong solution of nitre and then thoroughly drying them. The cause of the wicks of candles refusing to burn is, that the air cannot get access to them. The nitre, however, at a high temperature, will supply oxygen enough for this purpose.

Although our paper this week is a double-sheet, yet we are obliged to leave over considerable matter which we shall publish at the earliest possible moment. Among the communications thus delayed by press of matter we have to acknowledge a letter from "E. N. S.," on hydraulic mining in El Dorado county, one from Stockton on the Root blower and one on the Stockton and Copperopolis Railroad. We shall also illustrate in our next issues Barber's device for steaming rovings, Archibald's machine for the manufacture of iron hub wheels, a number of band saws, hub and rail car morticing machines, Tavean's sulky harrow and other devices, besides presenting our readers with a fine view of the East River bridge, and continuing our illustrations on the various branches of mining, mechanics and agriculture.

* * *

Mechanics' Institute Lectures.—The managers of the Polytechnic Branch of the Mechanics' Institute have arranged for weekly lectures for six weeks to come, and for monthly lectures for one year. Efforts will be made to continue lectures weekly, if possible through the year. At all events semi-monthly lectures can be counted on with almost a certainty. These lectures will all be of a high order. The next of the series will be given on Saturday evening the 17th instant, by Prof. Joseph Le Conte, of the State University; subject —"The Universal Law of Civilization, or Cyclical Movements." These lectures are *free*, and are always useful and instructive. The public generally are invited to attend.

* * *

The New Pile Driver.—The new patent steam pile driver, which we described several weeks since, is working regularly on the new railroad track at Oakland Point. It is said to accomplish two-thirds more work than the ordinary driver. Being more complicated, however, it is, of course, more likely to get out of order. How it will answer in the long run, we presume, remains yet to be proven.

The Diamond Drill.

[Continued from page 298.]

bottom of the screw shaft below the engine is the small steam pump, C C, connected by rubber hose with any convenient stream or reservoir of water, and also with the outer end of the drill-pipe by a similar hose having a swivel joint, as shown in the cut. Through this hose a one-fourth-inch stream of water is forced by the pump into the drill, from which it escapes between the diamond teeth at the bottom of the bit, D, and passes rapidly out of the hole at the surface of the rock, carrying away all the grit and borings as fast as produced. Where water is scarce or difficult of access, a spout is laid from the mouth of the hole to the tank or reservoir and a strainer attached to the connecting hose, so that the same water may be used over and over again with but little loss.

Fig. 3 shows a "No. 2 prospecting drill.' This machine is similar in construction and operation to the first, but larger and more powerful, has double engines, and is geared to twice the speed of No. 1. The engines are two oscillators, C, C, of 4¾-inch cylinder, 5-inch stroke, both attached to the same crank shaft. The boiler is tubular, 3½ feet by 7 feet, of superior construction, and designed expressly for this purpose; flues, 3 inches diameter; steam capacity, 12 horse power. The pump, P and water hose, H, fill the same offices as those in Fig. 2. This pattern is mounted on large wheels with broad felloes, for easy transportation in rough mining districts, and, like No. 1, is all complete in itself. It is especially adapted to well-boring, draining and prospecting. Bores holes from two to five inches in diameter, as desired, and to any required depth. Total weight, about 3,800 pounds.

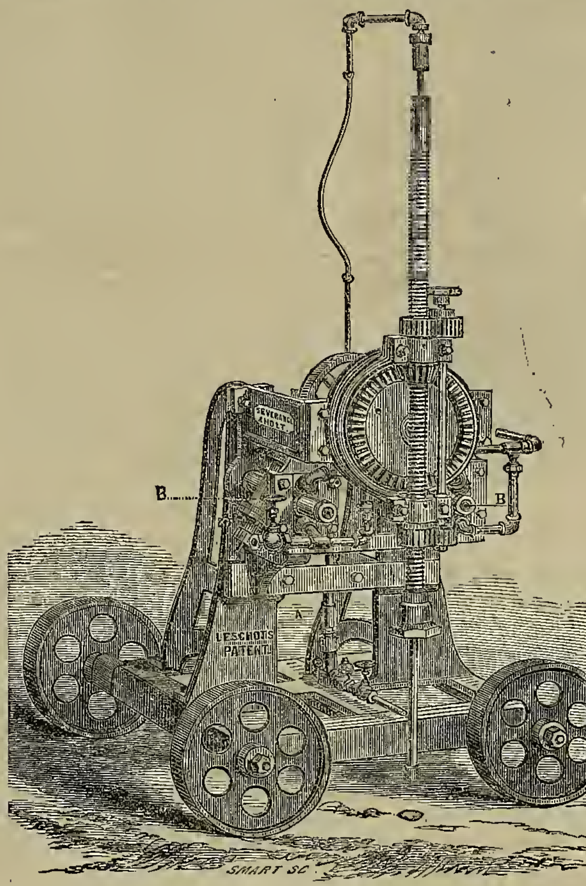

Fig. 4—Quarry Drill.

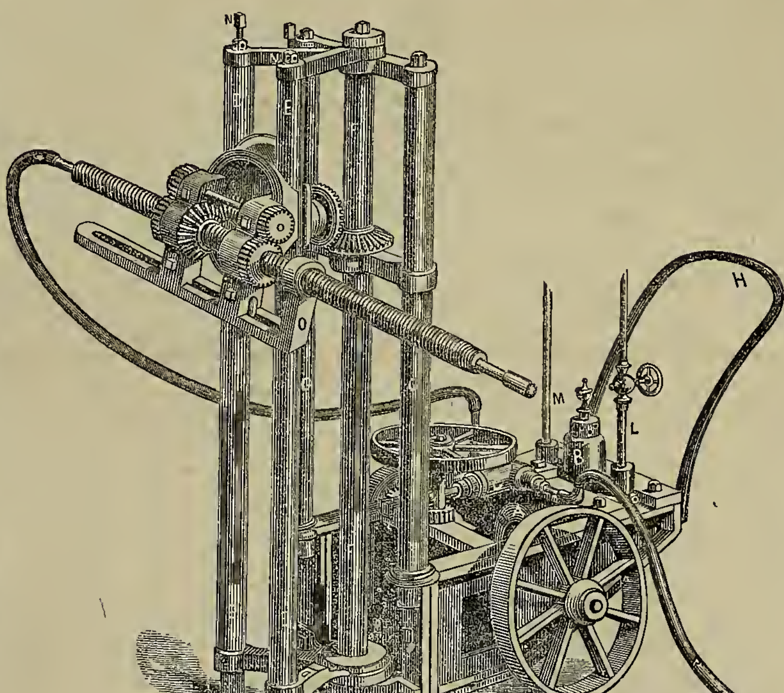

Fig. 5—Tunnel Drill.

Fig. 4 is an open cut or quarry drill, for railroad grading, quarrying and all surface excavations. Fig. 5 is the most approved form of steam tunnel drill, which is light and portable, being easily wheeled about by one man and will operate in tunnels from three to fifteen feet high. The essential points of these are identical with the preceding.

The value of this machine for prospecting, as it takes out a continuous core which shows the character of the ground it passes through, is especially great, and the testimonials of its successful working are exceedingly flattering. The diamonds last a long time, and can be reset with small cost by any mechanic, and other repairs are seldom needed. The speed of boring depends, of course, on the hardness and quality of the rock. We have seen it in operation both in the East and on this coast, and, although at first a little fearful that in hard rock it might not be able to compete economically with hand power, we have such certificates that we are compelled to recommend it.

In Colorado it has bored a *horizontal* hole 417½ feet long, with about ten dollars, cos for diamond points. It has bored 30 feet a day through hard trap rock in a number of places, and has sunk holes hundreds of feet deep. We have no room for the many testimonials from the East certifying to its remarkable success. Suffice it to say that it has been used in this State in Tuolumne county, in prospecting for the ancient river beds with succes; that it has sunk holes 300 feet deep in Telegraph hill; that an artesian well at the foot of Fourth street in this city is already 300 feet down, water enough to flow out of the top being obtained at a depth of 207 feet; that parties at Smartsville, desirous of testing it, sent down a block of tough granite, "almost as hard as crystallized quartz," which was bored at the rate of a foot in 3½ minutes; and that several other tests have been equally successful. It certainly appears to meet with wonderful success, and miners ought to examine it. Mr. A. J. Severance, one of the proprietors, is now in this city, and can be found by applying at the Grand Hotel, or parties may apply to Severance & Holt, 16 Wall street, New York. Personally, we have the greatest hopes with regard to this diamond drilling machine.

A Full List of Patents Issued to Pacific Coast Inventors.

[From Official Reports to DEWEY & CO., U. S. and Foreign Patent Agents, and Publishers of the Scientific Press.]

For the Week Ending April 26th.

Metallic Packing for Stationary Joints.—Harvey T. Lee, Marysville, Cal.

Steam Generator.—John C. Ludwig, Stockton, Cal.

Needle.—James W. Donaldson and Daniel Sheets, Suisun, Cal.

Animal Trap.—James H. Lord, San Francisco, Cal.

Rotary Mechanical Movement.—Addison Goodyear Waterhouse, San Francisco.

Pruning Shears.—Eli L. Nichols and F. A. Edler, Folsom, Cal.

Descriptions of these will be given in our next issue.

Note.—Copies of U. S. and Foreign Patents furnished by Dewey & Co., in the shortest time possible (by telegraph or otherwise), at the lowest rates. All patent business for Pacific coast inventors transacted with greater security and in much less time than by any other agency.

* * *

The coal deposit near Seattle, Washington Territory, has recently changed hands, and the new owners intend building a railroad to Lake Washington, where the coal can be shipped. The coal is said to be of good quality, containing but little sulphur. Half a ton was tested in the press rooms of the San Francisco *Bulletin*, and is pronounced a very good steam coal. The new company are to commence shipments to this city next fall.

* * *

Mr. A. B. Paul is soon to leave this city, we are informed, for the White Mountain district, Nevada. He is to put up his apparatus there for working the ores. We wish him all success.

The Central Pacific Railroad.

Years ago, many persons at the East were "pestered" with an individual, perhaps individnals, who broached the idea that the country needed an iron connecting link which shonld bind together the Atlantic and Pacific coasts. This idea, so generally oonsidered as an insane fancy at first, grew and gradually fonnd more and more supporters as the importance of onr extreme western settlements increased. Its valne, its necessity was urged upon the people, who slowly, at least on our Eastern border, recognized it, and to-day we cannot separate the history of onr country from that of the Pacific Railroad.

The bnilding of the Union Pacific Road was, after the line had been determined, a matter of comparative ease; not so, however, that of the Central Pacific. The engineer had to contend not only with great elevations, but also with the most unfavorable quality of ground. The western slope of the Sierra Nevada is so irregular, so broken up with ravines and cañons, often several thousand feet deep, with almost perpendicular sides, aud with narrow and sharp intervening ridges, that only the greatest skill combined with indefatigable energy and will could hope to overcome these obstacles. But these characteristics existed in California, and the Central Pacific, now an accomplished fact, is a noble monument of California enterprise.

It is getting to be the fashion to decry the grasping spirit of "huge monopolies." Let us, however, consider in this case, before joining in the popular cry, not only what our State owes to the promoters of tho railroad, but also how they persevered amid the greatest discouragement, and risked their reputation and their money at a time when no one else would venture, even in this daring State, to invest in so problematic a scheme! If they are reaping great rewards to-day, it is only what they have earned by their courage and foresight.

We had intended speaking more fully of the history of the road and of tho engineering difficulties, bnt the press of matter forbids our giving the details which we conld wish, and to make general mention of the fifteen tunnels, runuing up some six thousand odd feet, or the twenty-nine bridges, measuring over twelve thousand feet in length; or to speak briefly of the miles of snow-sheds, the deep cuts, the dizzy escarpments, would be but to repeat what has been published to satiety so lately. It would be well, however, to call attention to the immensity of the work of running a road some seven hundred and fifty miles long, and passing through the most varied country and climate, rising from nearly the level of the sea to an altitude of over seven thousand feet. And this length of road is patrolled daily by the sectiou men, whose duty it is to see that every bridge, culvert, shed, switch, rail or tie is in proper condition.

Some conception of the amount of traffic may be obtained from the figures relating to the rolling stock, the company possessing 167 locomotives, 133 passenger cars (first and second class), 1,928 freight, 9 express and 16 baggage cars, and by visiting the twenty-three acres of land covered with workshops at Sacrameuto. But we must cull from the data on hand only the fewest facts which will interest the reader and give him an idea of this gigantic undertaking, and perhaps we cannot attain this object better than taking the following data from the *Chronicle:*

The average cost of a locomotive is $12,500; of a passenger car, $7,500; of box freight cars, $900; platform freight cars, $600; sleeping cars, $11,500; Pullman's palace-cars cost $18,000 to $22,000. Remembering the number of cars and locomotives owned by the company, and doing a little multiplication, one gets some idea of the first cost of rolling stock.

In one month last year 911 men were employed in the work-shops at Sacramento, and 141 locomotives were in active service, giving employment to 108 engineers and 101 firemen; the pay roll for that month was $112,007. The total number of employés approximated to 5,000, with an extra force of 2,200 engaged in building new roads. There were traveled 286,641 miles, and matorial consumed to the amount of $139,280. The locomotives burned 8,250 cords of wood. These fignres include the Western Pacifio.

The following table of costs will be interesting to many: Total number of miles run on the Central Pacific Railroad, 212,106; pints of oil consumed, 18,349; cords of wood, 6,152; average cost of repairs per mile, in cents, 8.87. Average cost of engine-men per mile, in cents, 6.89; of stores, 1.59 cents; of wood, 20.09 cents; miles run to one pint of oil, 11.56; to one cord of wood, 34.47. Total cost of oil, tallow, waste, wood and engine-men per mile, 37.44 cents.

The men who manage this great work have, so far, shown a liberality of spirit in meeting the requirements for making their road popular with the public. Usually corporations, with such powers as are held by this company, are found to be shortsighted, and by high fares and high freight tariffs impoverish the revenue of their lines, and drive patronage and immigration away from their borders. But whenever a petition has been made by our wine merchants, frnit growers, and others, with good reasons for special reductions of freight, they have been met promptly and generously by the Central Pacific managers. It is well known that from the first they were ready to put down the through fares to a lower notoh than the oonnecting lines East were willing to join in.

The very men connected with this great railway seem to advance with the spirit of thoir work. We realize this when we visit Oakland and see the wonderful change which has taken place in a few months' management of the local road which forms the terminating link of the Western Pacific, the extra number of trains and cars that are run, the increased speed, the more comfortable seated coaches, and the wide-awake style in which the road is run and its improvements constructed. Several miles of extra wharf is being completed at Oakland Point. The company will soon have their cars running to a point near Goat Island, so that passengers from the East and from Oakland will reach the wharf in San Francisco within about fifteen minutes from the terminus.

The Central Pacifio Road proper extends from Ogden to Sacramento, but the company owns the connecting line of the Western Pacific, so that there is no change until one takes the boat at the pier at Oakland Point for this city. And this has been extended out to the close proximity of Goat Island, so that soon there will be a ferry passage of but fifteen minutes. It has branches south to San José and Gilroy (to be extended still further south), and to Stockton and Visalia, to be built immediately to the latter place. It extends north to Marysville on the way to Oregon, and other branches and connecting lines will be finished at no distant day. Its completion has infused a lively spirit of railroad engineering, and rendered necessary what, without it, would be but foolish expenditure, and thereby has vivified the whole State.

The traffic, as we before remarked, is rapidly increasing. The productive capacities of the State are so great that the trains are loaded to their greatest capacity, and more are being continually put on. We have now a daily through train, and it is expected that in a short time two such daily trains will be run; while every Wednesday, at 8 A. M. the Hotel Express starts with "palace accommodations;" so that, from the time of leaving San Francisco nntil reaching New York the passenger is not obliged to get out of the car. Besides these we have emigrant trains at greatly reduced rates. For the further benefit of parties, excursion tickets are issued to twenty or more persons, the charges varying, according to the number of excursionists, from $170 to $130 (currency), from San Francisco to Omaha for first class passage. Such tickets are good for thirty days, but will be extended, on request, to sixty.

The names of the prominent men connected with this road are widely known and will long be famous. Governor Stanford, the President, Crocker, Huntington, Hopkins and others, have held the highest places; the Chief Engineer, S. S. Montague; the General Superintendent, A. N. Towne, and the General Passenger Agent, T. H. Goodman, are familiarly known through their works to all on the coast; and the reputation of T. H. Judah, the former Chief Engineer, to whose exertions, in a very great measure, the building of the road must be ascribed, is dear to the whole Pacific slope.

Curiosities of Flour.

Wheaten flour becomes whiter with age; but at the expense of deterioration in flavor, sweetness and nutritive properties.

Some kinds of flour will keep better than others, under the same circumstances; that which contains the most gluten spoils soonest. When there is a large excess of gluten, it will sometimes spoil within a year, even when well put up in casks and kept in a cool and well-ventilated warehouse.

A part of the starch in wheat is often converted into sugar, in the process of grinding—as much as four per cent. of the starch is sometimes thus changed. This change is most readily affected when there is an excess of natural moisture in the wheat. A mutual action of the moisture and gluten seems to be induced by the heat produced in the process of grinding, which brings about this injurious change, if the flour is not soon cooled.

When flour comes from the stones very warm and is placed immediately in the large heap, without being allowed to cool, the series of changes likely to occur will be about as follows: Decomposition first sets in, during which a portion of the starch is first changed to dextrine, the dextrine into sugar, the sugar into alcohol, and, if the process continues, the alcohol to vinegar—*and so we have sour flour*. This action always commences in the middle of the heap, where the heat is longest continued, and increased by chemical action. Heat is finally communicated again to portions of the heap nearer the surface, which have been cooled by radiation, so that after a while the entire mass is spoiled.

From this it will be seen that flour, as soon as ground, should be conveyed to properly constructed receptacles or chambers, and cooled as quickly as possible. Much of the damaged flour thrown upon he market, in the Eastern States, becomes o by inattention in this particular. California flour is less liable to such damage, from the fact that our wheat is so dry that the incipient decomposition cannot readily take place.

We sometimes hear it stated that California wheat is *too dry* to make good flour. The trouble in such cases is that the bran will not separate to a sufficient extent to make *white* flour—still the darker quality of flour so made is really better and more healthy than that which has been made more perfectly white, by a cleaner separation.

Millers sometimes moisten the wheat previous to grinding, to make the separation more perfect. If such flour is immediately packed in sacks or barrels, without being allowed to dry or cool, some, or all of the changes mentioned above are very likely to take place, and we have *musty* or *sour* flour, according to the extent to which tho change goes on. If decomposition takes place without much heat, we have *musty* flour; if that action is accompanied with a sufficient degree of heat, we have *sour* flour, by the progressive changes from starch to sugar, to alcohol and to vinegar.

From these considerations our readers will infer the advantages of buying, for household use, freshly-ground flour, and that which has been properly manipulated.

Agriculture for California—Practical Views.

We are having just now a very good agricultural season, in spite of our fears during the early winter. These fears will not be so groundless always, for we are sure to have that dry winter at some time. It is therefore wise to anticipate and be ready for it. The disaster which one winter of only four or five inches of rain would bring to the State, under our present system of farming, is worthy of general consideration. It is not only the farmer who would suffer, but financial distress, if not ruin, would overtake half the mercantile and industrial interests of the State. With a proper system of cultivation of the soil, a rainfall of only five inches would guarantee a fair crop.

Irrigation, which has been suggested by many of the newspapers of California, is impracticable to any great extent here. A few bottom lands and a strip along the base of the Sierra Nevada might, with great expense, be subjected to irrigation by means of reservoirs, canals and ditches, but these would be local and very limited (except with inadequate expenditure) in their application. But no application of water to a plant is so serviceable as that which is furnished at the root and not upon the surface of the ground.

Heat and moisture are the indispensable requisites to vegetation; and the greater the amount of the two elements administered in proportionate quantities, the greater will be the growth. This is instanced in tropical regions where the great swamps, bayous and river bottoms, under the intense heat of the equatorial sun, produce the rankest and most luxurious vegetation.

It is thought that owing to the absence of summer rains in California, we are unable to produce root crops such as require to be planted after the season of frosts has passed and with it the season of rain. This is a great mistake. A very little moisture with heat will cause almost any (except the hardest) seeds to germinate; and once the germ is put forth in a loose and friable bed of earth where its roots may easily penetrate and distribute themselves, a small amount of moisture will keep up the growth of the part above ground as well as that below.

This condition is to be obtained more readily by subsoiling than by irrigation; for, by the former, the ground is broken to a depth of twenty inches, in which mellow bed the roots will penetrate as far down as the loosened soil exists, and will there receive the moisture which always exists in the earth, and which, by the sun's heat, is drawn towards the surface and evaporated; while, by irrigation upon the surface of the ground, tilled in the ordinary manner, a crust of hardened earth becomes formed, through which, unless it be kept soft by great and almost constant saturation, vegetation is able to make but sickly growth, its roots having but little depth of loosened earth in which to penetrate. In fact, in irrigated soils the roots will seek the surface where it is most moist, rather than the hard ground just beneath the plowed soil, whereas on subsoiled land the twenty inches of loosened earth, like a sponge, absorbs moisture from below, and the roots, seeking that source of moisture, penetrate downward, receiving nourishment, vigor and fruition.

As an illustration of what subsoiling will do for vegetation after one of our dry winters, I will mention an experiment made after the winter of 1863-64, when but ten inches of rain fell. On the first day of July, 1864, I selected on the highest part of my land at San Mateo upon hilly ground, a smooth, hard piece of sod ground, a rod square, that had never been plowed, and which was to all appearances as dry as the peak of Mount Diablo. I had it dug out with pick and spade to a depth of twenty inches, throwing all the earth out of the excavation, and then putting it back again. I thus had a good mellow bed. The earth for the first six inches was as dry and hard as if it had been in an oven. Below that depth it contained only dampness sufficient to distinguish it from being dry. In this rod square of loosened earth I planted about thirty pieces of potato, and raked the ground over smoothly, and left the experiment to its results. Not a drop of water was put upon it. Of course no rain fell on it that season, and nothing whatever was done but to leave Nature to its course. For five weekst here was no sign of vegetation apparent. Not a weed nor potatoe top was to be seen; and after daily inspecting my dry dust bed for that period, and I had begun to consider the experiment a failure, I found the green buds of my potatoes just peeping through the surface. From this time they grew marvelously, and before the first day of October the whole rod square was one thick bed of potato tops, of the deepest green color, an inch in diameter, two feet in height, and covering the ground so that the soil was not visible. On the first day of November I had the crop dug up, and got 125 pounds of potatoes as large as my double fist, and as fine as any I ever saw or ate.

After the experiment it would be useless for any one to try to convince me that potatoes, and beets, and turnips, and melons, cannot be successfully grown in California upon any but what is known as bottom land, or that they must be planted before the rainy season has terminated. On the contrary, I am convinced that there are very few places in this State where all the root crops may not, with subsoil plowing, be cultivated quite as successfully as in any other part of the world.

With regard to the cultivation of grain, the same system of subsoiling would always insure a crop in the dryest season, besides permitting later sowing of the seed.

The additional expense of subsoiling would not exceed $10 per acre, and the grain to the crop would be not less than 50 per cent. The increase cost would be more than counterbalanced by the saving in many respects; to wi: in the quantity of land required and the interest on its value; the lessened area to be fenced, the saving in seed, and the diminished cost of reaping; one acre producing the crop usually got from one and a half acres.

Should subsoiling be too expensive for all farmers to adopt, I would suggest, as an improvement upon our present system of grain sowing in the spring months, after the rainy season has been almost consumed in preparing the ground, that we take a lesson from the example that Nature here affords us. The wild oats of our hills drops its seed upon the ground in May, and the volunteer crops of grain, which are often as good as those fresh sown, come from seed dropped during the harvest months of June and July.

I would then sow the grain, not in winter, but in summer. At the time of harvest the soil, having been shaded by the growing grain in the early summer months, has not become hard and baked as it becomes while in the stubble. It is still mellow from the winter's plowing, and at that time can be plowed almost as easily as after the first rain of autumn. The days are long and work not interrupted by rainy weather. Laborers are abundant and on the premises, and were the ground then plowed and the seed then sown, the farmer's work would be at an end, and with the first shower of winter he would find his growing grain giving certain promise of abundant harvest, be the season wet or dry. In this State too much weight has been attached to the advantages or necessities of irrigation in the growth of grain, vegetables or fruits.

I have an orchard of 1,100 assorted fruit trees and a vineyard of 3,000 vines, both planted upon a hillside, and now under cultivation under my own supervision for fifteen years past. In planting both trees and vines through several years (as they were not all set out in one season) some were put into the ground as late as the month of April, and in no instance was ever a drop of water applied to either tree or vine except that which fell in heaven's own showers. Large and deep holes were made to receive the roots, and this subsoiling plan succeeded. My orchard produces as fine fruit as ever grew—peaches, pears and apples often weighing nearly a pound each. My vines produce an average of fifteen pounds of grapes each, with bunches often of three or four pounds weight.

What can be done on the hills of San Mateo can be done on the hills of Sonoma or Contra Costa, or of the Sierra Nevada.

The State is rich in fertile lands upon the hills as well as in the valleys, and under its genial climate we can, with intelligence and industry and the wise application of Nature's lessons, make it the garden of the nation and the paradise of its people.—*Evening Bulletin*,

* * *

To Remove Mildew from Clothes.—Mix soft-soap with powdered starch, half as much salt, and the juice of a lemon, lay it on the part with a brush; lay it on the grass day and night till the stain comes out. Iron stains may be removed by the salt of lemons. Many stains may be removed by dipping the linen in sour buttermilk, and then drying it in a hot sun; wash it in cold water; repeat this three or four times. Stains caused by acids may be removed by tying some pearlash up in the stained part; scrape some soap in cold soft water, and boil the linen till the stain is gone.

Wood Fiber from the Air.

A work of science gives the following novel experiment, which settles questions of some importance in philosophy: Two hundred pounds weight of earth were dried in an oven, and afterward put into an earthen vessel. The earth was then moistened with rain water, and a willow tree, weighing five pounds, was planted therein. During the space of five years the earth was carefully watered with rain water, or pure water; the willow grew and flourished, and to prevent the earth being mixed with fresh earth, or dust blown to it by the winds, it was covered with a metal plate perforated with a great number of small holes, suitable for the admission of air only. After growing in the air for five years, the tree was removed, and found to weigh 169 pounds and about three ounces; the leaves which fell from the tree every autumn were not included in this weight.

The earth was then removed from the vessel, again dried in the oven and afterwards weighed; it was afterwards discovered to have lost only about two ouncesof its original weight; thus 169 pounds of woody fiber, brake, or roots, were certainly produced, but from what source? The air has been discovered to be the source of the solid element at least. This statement may at first appear incredible, but on slight reflection its truth is proved, because the atmosphere contains a notable amount of carbonic acid, which is a compound of oxygen and carbon—the latter forming nearly the entire weight of the wood after the extraction therefrom of the water or sap. Moreover, the rain water which was used from time to time in moistening th earth, also contains, in solution, quite a number of substances which go to make up the wood. Even the silica, lime, potash, magnesia, iron, etc., which form the incombustible portions or ashes of the wood might all have been obtained from the water, taken into solution possibly, while passing over the roof form which it was caught. Had distilled water been used differet results would no doubt have been obtained.

Vegetable Instincts.

A tree which is fond of water, when planted near some brook will set off all its principal roots in that direction. How does it know the water to be there? And how does it know that it will be able to reach the border of it? To say, in popular phrase, that the water attracts the roots in that direction, is to invent a new and very remarkable sort of attraction that pulls at roots in the ground, and turns them out at the point of starting—is a something created to account for the fact in question, which is even more difficult than the fact itself. Mr. Madison, for example, had an aqueduct of logs, which, in reaching his house, passed by a tree especially fond of water, at a considerable distance from it. Abreast of the tree there was an auger hole in the log that had been filled with a plug of soft wood. Exactly thitherward the tree sent off a long stretch of roots, which forced their way through the plug, choking up the passage, and were found there drinking like so many thirsty animals. Was it then the soft wood plug that attracted these roots? It certainly should be, on the attraction principle; for the water was just as near at other points as here. It is said that a strawberry planted in sand, with good earth a little way off, will turn its runners all in the latter direction, and if the good earth is too far off to be reached, the plant will make no effort on that side more than on the other—which is equivalent to the saying that the plant has, in its life-principle, an instinct of measurement. It does not measure the ground and then itself, and then compare the two; but it has an adaptive power by which, without comparison, it graduates its action by its possibilities.

* * *

Tall Stories from Florida.—In Florida there are many lakes which have holes in the bottom and underground communication, so that they will sometimes shrink away to a mere cupful, leaving many square miles of surface uncovered, and then again fill up from below and spread out over their former area. Some of them have outlets in the ocean far from shore, bursting up a perpetual spring of fresh water in the very midst of the briny saltness of the sea. In times of low water, during a long, exhaustive, dry season, men have gone underground in one of these subterranean rivers from lake to lake, a distance of eight miles.—*Lippincott's Magazine.*

"How Crops Feed."

To write a book that is both interesting and valuable is an art that is understood by only a few of our best book-makers. But such a book is now before us, under the above title, published by Orange Judd & Co., of New York, and written by S. W. Johnson, Agricultural Professor of the Sheffield Scientific School, of New Haven, Conn.

"How Crops Feed" is a companion and complement of "How Crops Grow," written by the same accomplished hand, now well known and appreciated both in this country and Europe. The latter consists of a treatise on the chemical composition, structure and life of plants; while the one now before us treats upon the atmosphere of the soil, as related to the nutrition of plants.

The author "has not sought to excite the imagination with high-wrought pictures of overflowing fertility as the immediate result of scientific discussion or experiment, nor has he attempted to make a show of revolutionizing his subject by bold and striking speculations. His office has been to digest the cumbrous mass of evidence in which the truths of vegetable nutrition lie buried out of the reach of the ordinary inquirer and to set them forth in proper order and in plain dress for their legitimate and sober uses."

This book will be most cordially welcomed by all who appreciate the present scientific aspects of agriculture and hold to the generally-accepted fact that true theory is the surest guide to successful practice. The collection and arrangement of facts therein set forth must have cost the writer long and severe study and labor. His method has been to place before the reader all accessible facts, to present their evidence in as plain and simple a manner as the subject will admit of, and to merely record the verdict according to testimony. The opportunities of the author have evidently fitted him for this work; and his familiar and easy style enables him to bring his thoughts down to the comprehension of everyone. Mr. Johnson is a thoroughly practical man. He was brought up a working farmer, and carried his practical knowledge into the laboratory, where for twenty or twenty-five years he has devoted his labor and time to the thorough study of the science of agriculture.

In the mechanics of agriculture, there has been a steady advance for the last hundred years; but the chemistry of soils and their action and that of the air and other gases upon the growth of plants are subjects the knowledge of which dates back but little over twenty-five years. The study of agricultural chemistry is now held at its true value; and books like the series which Mr. Johnson is now publishing are beginning to be properly appreciated.

It is but a few years since we were taught that the roots of plants took up little particles of dirt and manure and transformed them into vegetable structure. But science has now revealed the fact that all compounds, whether mineral or organic, must first be decomposed into their original elements before they can form plant food. Science has also taught us how one can greatly assist Nature in this work of transformation by placing in mutual presence the minerals and organisms which Nature needs to carry on her works. "For instance,"—quoting from a distinguished agricultural writer,—"we are treating a soil that is sterile after a liberal appropriation of manure; we puzzle over the reason until an analysis shows the presence of copperas, a poison to plant as to animal life. Without further information we might be at a loss to remove the poison and renovate the soil; but the chemist, aware that lime will displace the oxide of iron from its combination with sulphuric acid, suggests the use of that mineral, not as a manure, but as a chemical agent, the problem is solved. The noxious substance is changed to harmless sulphate of lime and inert oxide of iron, and crops *grow* thriftily where they refused to *sprout* before. A similar illustration may be found in another use of lime, in the reclamation of swamps and peaty lands. Research has made known the existence in such soils of acids derived from organic decay, and not only hurtful to plants, but locking away from their reach the ammonia that would otherwise feed them. The chemist explains that lime attacks these compounds, neutralizes the acids, and liberates the ammonia, so that the scientific farmer, turning against Nature the force of her own laws, makes available by art for the benefit of his crops the substance that the natural chemistry of the earth had cunningly hidden from their reach. Chemistry not only tells how, in these and a hundred other ways, we may change and ameliorate the condition of the soil, but tells why and wherefore some soils are naturally better than others."

As a preliminary work and a familiar hand-book for scientific farming we know of no more valuable treatises than the two we have named. Our farmers should buy and read them both. Either, however, may be profitably read and studied by itself. "How Crops Feed," especially, contains much that every farmer should know. For sale by A. Roman & Co., of this city. Price, $2. It may be interesting to some of our readers to know that Prof. Johnson is now at work on a third volume.

Shasta County.—A large mass meeting was held lately in Shasta county to protest against the Deputy United States Surveyor, who has returned the mineral lands of the county, it is said, as agricultural. While a considerable portion *is* agricultural, still this action is manifestly wrong if it denotes *all* as farming lands, and we hope that the committee appointed by the meeting will be able to get the matter righted without delay or troublesome expense.

Fig 2

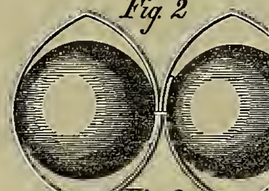

Fig 3

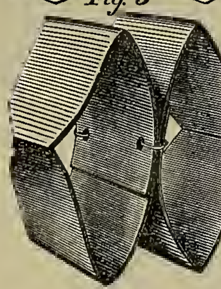


The Geological Observations of the so-called Lime Mountain at Segeberg in Holstein led to the conclusion that rock-salt was present at some depth below the surface. A prospecting hole was sunk, and after sinking 472 feet, salt solutions and pieces of salt were obtained, and the operations are being pushed on to determine the character and size of the deposit.

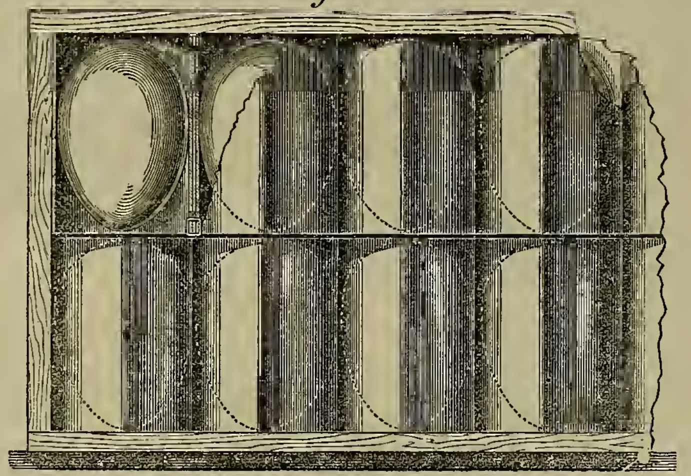
The Sutro tunnel is in over 1,000 feet, and is progressing favorably. An increased force of workmen is employed.

Packing Eggs, Fruit, etc.

A neat device for this purpose, which has the merit of being exceedingly cheap and is said to answer its object very well indeed, consists in the employment of pockets, made in pairs, of strips of stiff paper, leather, or bark, folded in the manner shown in Fig. 3, of the proper size, and arranged in tiers in a box or other case, with dividing boards of stiff paper between each tier to prevent the egg or other substance from coming in contact with its fellow, and also to provide for a free circulation of air, whereby the package may be kept perfectly cool.

Fig. 1 represents a package of eggs arranged in this manner for transportation, and Fig. 2 represents a top view of one pair of pockets. The device is very simple and is made by bending the strips of leather or other material into the shape shown and fastening the two ends and the centre part by a couple of strings. By this mode of packing, each tier is supported by the pockets below so that the articles packed do not press on one another. It is claimed that there is an economy of space and weight over the common methods of packing in oats and the like, and that there is less loss by heating, jamming or breaking.

Fig. 1



SMITH'S DEVICE FOR PACKING FRUIT, EGGS, ETC.

The package can be used, the inventor says, for transporting grapes, by running a stick through the middle hole and letting it rest on the notched sides, so that the bunches can hang down inside. He applies it also for various other purposes. It was patented in November, 1869, by Austin S. Smith, of Lawrence, Mass., to whom may be made any application for further information or for the purchase of State rights.

The most northerly mining works in the world are at the Altenfjord, on the northwestern coast of Norway. A piece of copper ore, found by a Lap-woman, was shown to an English merchant in Hammerfest in 1825. This merchant obtained a privilege from the government for the working of the mines, and raised a company in London with a capital of $375,000. Marmier reported, in 1842, that more than 1,000 workmen were employed in these works, and that often upwards of ten vessels at a time were busy unloading coals at Kaafjord for the smelting of the ores. Other works were afterwards opened on the opposite side of the bay at Paipass.

Hammerfest, on the island of Hvalö, in 70° 49′, is the most northerly town in the world. It has a population of some 1,200. Its chief traffic is in fish, reindeer skins, wolf and bear skins, train oil, walrus tusks and the like. Although situated so far to the north, in summer the heat is sometimes oppressive, and in winter it is never too cold to prevent fishing. The mildness of the temperature is due to the large expanse of water in the neighborhood and to the influence of the gulf stream.

The Scarlet Fever and How to Treat It.

A lady residing at Reno, Nevada, where the scarlet fever has lately been raging among the helpless innocents, cutting down, as it always does where it prevails, many a sweet child, the sunbeam of the household and the hope of loving parents, writes to a sister, and from the letter we are permitted to extract the following. We have strong faith in good nursing. An intelligent, thoughtful and courageous mother's tender and affectionate care is the very best shield against the ills and dangers that assail weak and frail childhood. While medical treatment is often necessary, good, careful nursing is always indispensable:

"The scarlet fever has been fearful among the children here this season. Several have died with it. Two of my precious ones—E. and L.—have had the fever, but, with the permission of Providence, I have saved them without the aid of a physician. I tended and took care of them myself, and they got through better than any other children that I know about. I will tell you my manner of treatment. You may, perhaps, be sometime obliged to encounter the disease. We never know till trials are upon us the importance and satisfaction of being equal to emergencies. My experience in this case may help you to better understand what is proper to be done in such fevers.

The room I kept carefully warm both day and night. Thorough ventilation is requisite, but no draft of air should be allowed to strike upon the patient. One can not be too particular about having plenty of pure air, and of guarding against exposure to drafts.

Externally I applied "Pain Killer" freely to the throat and chest; I also gave it internally mixed with a little milk and sugar very sweet, as a *gargle* and as a *drink*. Every second day I gave a little Hamburg Tea; after the breaking out, warm lemonade. I also gave cold water in small quantities whenever the patient wanted it. I used vinegar and water on the head, face and hands as often as required. When the fever was high I bathed with warm lye water, applying with a sponge as much under the cover of the quilts as possible. To avoid giving the patient a cold the greatest care should be used in bathing the body while the fever is raging. I was so successful with my children that Mrs. H. followed my advice with little Alice, and she is well. You may be surprised at the simplicity of my treatment; but Nature's ways are always simple, although it often requires much study to find them out."

Vegetable Giants in Australia.

Within a day's journey of the metropolis of Victoria may be seen the loftiest trees of Australia, and perhaps of the world. In the gulleys of Dandenong, as well as in some of the remote valleys of the Upper Yarra, a kind of Eucalyptus, botanically known as *E. Amdelena* (almond-leaved gum tree), attains such a marvelous height as to rival in this respect the *Washingtonia* of California. The stems rise as straight as masts, but far exceeding the masts of any naval structure. The height of the loftiest ranges from 400 to 500 feet!

A fallen tree measured from 480 to 500 feet in length. Another in Dandenong showed a height of 290 feet to the first branch. At the height of 365 feet, it measured nine feet in circumference. A still larger tree at Berwick measured eighty-one feet in circumference at a distance of four feet from the ground. The stems, with the exception of the base, are beautifully smooth and of an ashy color. The wood is excellent for shingles, and splits with facility.

Large numbers and several varieties of the *Eucalypti* have been planted in this State. They are beautiful for ornament, useful for timber, and grow with great rapidity. The seeds are very minute, yet they germinate with the utmost facility.

Rye, as a crop, is not properly appreciated. It springs up early in the season and is valuable as a grain crop long before clover is large enough for feed, and as a seed crop, it is valuable for bread—more wholesome mixed with corn than wheat bread. Sown early, it makes excellent fall feed for stock after grass has ceased to supply pasture for stock.

Artificial Propagation of Fish.

This subject is assuming a national importance. The destruction of fish is carried on with such wholesale rapidity that, unless some earnest measures are taken, no place inhabited by man will long furnish a sufficient supply of this valuable article of food. We have at present an abundance of certain kinds of the finny tribe, but cannot hope to retain the supply with the present rate of destruction—witness the reported wanton slaughter at Lake Tahoe by means of submerged explosives—unless we take speedy action on the subject. The Connecticut river was once, it is believed, as good a salmon-producing stream as any in America, but for years this fish has scarcely been known in its waters. Let us take warning. The Department of Agriculture declares, with regard to the Pacific salmon rivers, that "if the strong arm of law is not interposed, but few years will elapse before the efforts of fish-breeders will be called into requisition to restore the salmon to those waters. If protected, they may continue to yield millions annually; if neglected for a few seasons, they will shortly become worthless."

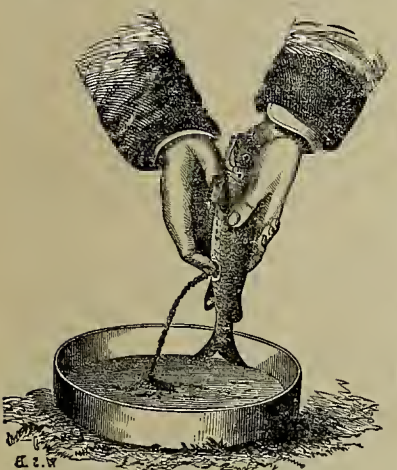


Fig. 1—Mode of Discharging Ova.

In view of the present state of affairs, and in the hope of interesting some one in a subject at once important and conducive to the education and gratification of a taste for rural pursuits, we propose giving some facts to our readers about this matter, which is attracting so much attention at the East at the present time.

Its History.

In other countries the value of fish culture has been recognized for some time past and the art practiced with considerable success. Pisciculturists have traced it back to the Chinese, who have practiced it for ages. From China the old Romans imported it, and thereby supplied their tables with the choicest dainties. From Rome we trace it later to the Monks of the Mountain, by one of whom the present plan of hatching the fish in boxes is said to have been invented. The art seems, however, to have had but a very limited range, and we hear not much of it until a German by the name of Jacobi discovered the method of artificial fecundation, and published an account, in the *Hanover Magazine*, in 1763, of the result of thirty years of research. In the kingdom of Hanover, near Nortolem, the first trials were made with great success. In 1837 Mr. John Shaw put the process into practice with salmon in Scotland, and in 1841 Mr. Boccius stocked several streams in England. MM. Gehin and Remy, through personal observation, discovered the process in France in 1841, but the subject did not attract much attention until 1848, when the French Academy of Sciences was apprised of the fact, and immediately appointed a commission to investigate the matter. In 1852 a government establishment was erected at Huningen, and the results there obtained for the first time, apparently, really attracted public attention and established the popularity of the practice. Since then the various European States have enjoyed a manifest increase of fish through artificial propagation. Several of the States of this country have entered into the matter, and the governments of the Eastern and Middle States have appointed commissioners of fisheries.

Natural Production and Hatching.

The method in which the fish spawn in nature was observed in the case of trout by MM. Gehen and Remy, who gave the following results of their observations:

The trout come together in a shoal and choose a current with a gravelly bottom. They dig a round hole and place in this a line of stones. The female then passes over this line, gliding over and rubbing against or resting upon them. This she does some twenty or thirty times until her eggs are all laid in the crevices of the gravel. After this the male in the same manner emits the milt which covers and fecundates the eggs; then with tail, fins, head and belly he covers the eggs with gravel. Now a second female commences and in the same manner lays her eggs in a parallel line with and against the first row. When the fecundation is complete, all unite and heap up stones and gravel over the eggs. These remain in this way a month or so, when the little fish come out between the interstices of the gravel and seek in the tranquil waters near the shore a place of safety.

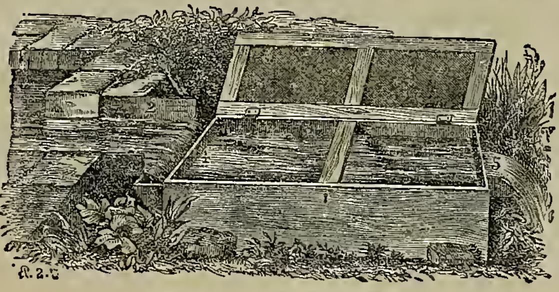

Fig. 2—Hatching Boxes.

Process of Artificial Fecundation.

The fish should be watched for several weeks beforehand so as to know when they are ready to spawn, or they may be caught when they appear to have nearly reached their term and be confined in some good, roomy place (but not in boxes), where they can be taken out with a net and examined. When ripe they may be distinguished by their swollen sides and pouting anus and their uneasy movements, and, on being taken from the water and examined, by the fact that the slightest pressure suffices to express the eggs or the milt.

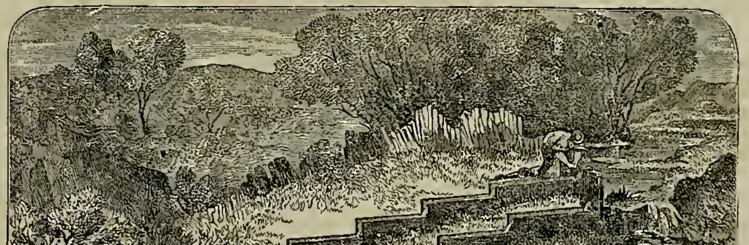

Fig. 3—Hatching Boxes.

When the proper time has arrived a few fish are caught with a net and placed in a tub or bucket. As they are taken they are examined one by one to see if they are ripe. Those not ready are put back into the water. For the reception of the eggs almost any flat vessel will answer if it is broad enough so that the eggs will not be heaped up, and if carefully cleaned. This is filled about three-quarters full of clear cold water.

A female fish is now taken and held over the vessel (as shown in Fig. 1) by the head and thorax with the left hand, while the right hand, its thumb on the belly and its fingers on the back and sides, is passed, like a ring, lightly from the head to the tail, thus pressing out the eggs. If these are ripe the lightest pressure suffices to expel them. But if it appears that a greater pressure is necessary, one may be sure that the operation is premature and the female must be replaced in the pond, and allowed to remain there until her full time is accomplished. Care must be taken that this will soon occur, for if a female fish is kept captive any great length of time in a circumscribed place her eggs will spoil.

If the fish is too large for one operator, another can aid by passing his fingers in the gills; and, if the convulsive struggles are very violent, it may be necessary also to hold the tail.

Eggs which have lost the reproductive faculty may be recognized by two characteristics: the flowing out with them of a foreign matter, which gives the water a muddy hue when the eggs begin to fall into it; and the white color of the eggs when they come in contact with the water. If neither of these appearances can be observed, we may be almost sure that the operation will be successful. Eggs must not be piled up too thickly in the vessel, as, in this case, they may not all come in proper contact with the milt of the male. If the process of expressing the spawn has brought out any of the mucus secreted in the intestines, the water must be immediately changed to free it from any impurity, care being taken that the eggs do not become dry. If the eggs are agglutinated together naturally—as in the case of the perch, carp, bream, roach, etc.—care must be taken not to pull them apart.

The male is then treated in the same manner to express the milt, which, if ripe, will flow abundantly, white and thick, like cream. The water is sufficiently saturated when it has assumed a whey-like appearance.

To spread the fecundating particles everywhere and uniformly, the mixture is agitated and the eggs turned over with the hand or a fine hair brush. After two or three minutes rest, the fecundation is accomplished and the eggs and water are emptied into the hatching basins. Many prefer to change the water with the milt of the male first, and then to express the spawn into this. The milt of a single male will suffice to fecundate the eggs of a large number of females, if he is treated properly. Undoubtedly by this process many breeds can be crossed and varieties produced.

Hatching Apparatus.

For hatching are required clear running water, boxes of some kind to hold the spawn, and protection from enemies. Spring water, of 40 to 45 degrees temperature, appears to be best adapted for the business for several reasons, the temperature of springs being more equable than that of rivers, and there being less danger from sudden increase of volume, etc. The boxes are of various forms and construction, but their general principle is the same.

In Fig. 2 we give the box introduced by Mr. F. Francis, and adopted by the Thames Angling Preservation Society. The box is made of elm and is 4 feet long, 15 inches wide and 10 inches deep. At the upper end is a zinc trough (3) which is about three quarters of the width of the box. At each end of the box a piece is cut out six or seven inches in width, and through these the water flows into (and out of) each box. These openings are covered with perforated zinc, which allows the water to flow through, but keeps foes out and the young fry in. The openings are not carried all across the boxes, as the shoulders left make eddies, favorable as resting places to the fish when first hatched. The water from a reservoir (1), made by bricking up a small rill, flows over a shoot (2) into the trough (3), and, after passing through the box, is led by a zinc shoot (5) into the trough of the next box placed at a somewhat lower level. There is a cover to the box to keep off mice, birds, and also men.

Fig. 3 shows another apparatus described by Mr. F. Buckland as employed at the Galway Salmon Fisheries. The boxes are 6 feet long, 1 foot wide and 7 inches deep. Each box overlaps the succeeding. The water of a stream is dammed up and the supply regulated by a gate at the upper end of the boxes. Perforated zinc here protects against foes.

The bottom of the hatching apparatus is covered a couple of inches deep with coarse gravel, from the size of gooseberries to that of plums, and of irregular shapes, with larger stones here and there. An inch depth of water is sufficient to cover the ova. The eggs are distributed regularly over the gravelly bed and among the interstices of the gravel, care being taken to place them in the crevices. Such a box as that shown by Fig. 2 will hold four or five thousand eggs. Over these a layer of coarse stones—an inch or an inch and a half square—may be placed. A small amount of water is sufficient; but it is better to have more while the ova are unhatched than is necessary for the young fish, so as to prevent deposits being formed over the eggs. If the water used is not very clear it may be filtered through gravel, charcoal, etc.

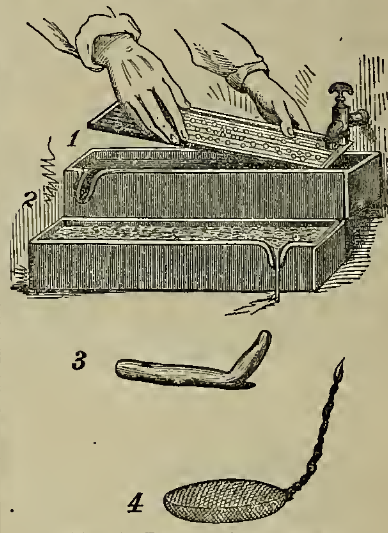

Fig. 4—In-door Apparatus.

The in-door apparatus is considered preferable in England to the out door, especially for experimenting on a small scale. One of these, recommended by Mr. Buckland in his work on "Fish-Hatching," is shown in Fig. 4. The troughs are made of zinc, two feet long, five inches wide, four inches deep, with one side of glass. No. 1 is furnished with a bed of glass rods, which the operator is placing in the upper tank. Beds of gravel are just as good as these glass rods, except that the latter afford a better opportunity of observing the eggs at their various stages of development. Boards are fitted on the tops of the troughs to exclude the light while the eggs are being developed, and there must be a steady flow of a gentle stream of water. No. 3 is the catcher, for moving the eggs without touching them. Place the finger on the end of the straight tube, immerse it in the water and bring the lower end opposite the egg or impurity to be removed. Then, withdrawing the finger, the water rushes into the tube and with it the object to be withdrawn. No. 4 is a net of common wire for catching the young fish. This apparatus can be fixed up almost anywhere under cover, except in a *hot* greenhouse.

[TO BE CONTINUED.]

The *Galaxy* for May comes to hand in reasonable time. The enterprising management has added another feature of interest to the magazine by securing the services of Mark Twain, who edits a department under the head of "Memoranda," and which is peculiarly Twainish in style. The *Galaxy* is one of the best of the kind which we receive.

An Excellent Institution.

Last December the Victorian Mining Museum at Melbourne, Victoria, was thrown open to the public. Here were collected ores and minerals from all parts of the colony, so arranged and labelled that persons could see the occurrence of different metals in different regions, and not only gain a knowledge of what had been found, but also receive some little clue as to what one might be likely to find or not to find. The scope and plan of the institution seem most excellent and worthy of imitation. Mr. R. Brough Smythe, in his opening speech, made a fow remarks on the origin of the collection, the methods used, and the objects sought for.

"It occurred to me in 1859, that if a system were adopted under which all the ores and metals discovered by mining surveyors, and other persons willing to contribute, could be collected and examined, and their character and value ascertained, and the information thus gained made known, much good would be done—even if the results did not extend beyond the preventing prospectors and miners from wasting their time and money in unprofitable labors; and during the ten years in which I have been engaged in collecting specimens, I can safely say that thousands of pounds have been saved by the information afforded to miners and others who have sought for advice.

"Much light has been thrown on the geology and physical geography of the country by keeping up a connection of this kind with prospectors; and the reports emanating from the department and many scientific works lately published in Europe, show that substantial aid has likewise been rendered to the mineralogist and the geologist.

"I am not aware that in any country in the world except Victoria has an attempt been made to collect systematically and to analyze all the mineral products which are from time to time discovered.

"Had such a system been in operation in Britain some twenty years ago, several millions sterling would have been saved to the people, because the ironmasters would have known of the occurrence of iron ores in localities where they are plentiful, and can be cheaply wrought, long before a mere accident brought them into notice. In the manufacture of aluminium, fit for the production of aluminium bronze, the minerals at present indispensable were discovered by chance, and not as the result of systematic inquiry. But little even at the present day is known of the character of the pyritous minerals in which Britain is so rich, and whence she derives so much wealth. A hundred instances could be adduced of minerals being discovered recently by accidont which, under the system we have in this colony, would have been known long ago, and much loss to manufacturers thereby prevented.

"In order to test practically the theories of those geologiets who maintain that quartz veins decrease in productiveness in a ratio with the depth from the surface, I caused to be collected in all parts of the colony blocks of quartz from the veins. From the descriptions in the catalogue you will observe that each block is carefully described; its obvious physical characteristics are noted, the proportion of sulphides in it, the yield of gold per ton, the depth from the surface at which it was obtained, the depth of the water line, and the thickness of the reef, are given on the authority of the mine-owners. All the facts are plainly and clearly stated, and the result has been to prove beyond doubt that reefs do not as a rule decrease in richness with the increase of the depth from the surface. More than this, we have gained some slight clue to the mode in which gold occurs in reefs, and to its distribution."

◆

The Russian Government has decided to sell all the mines and smelting-works belonging to it. As conducted heretofore, it has been considered necessary, apparently to have an official with a long sword to superintend the labor of about every two workmen; which renders operations rather expensive and dividends exceedingly small.

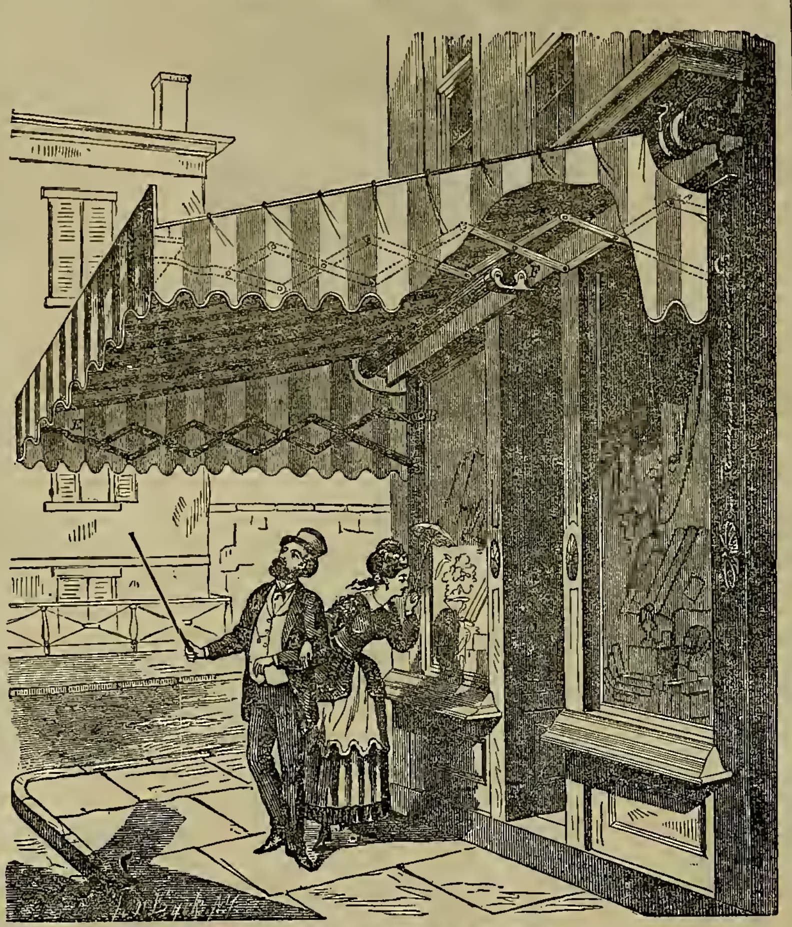
The Stetefeldt furnace continues doing well according to all accounts. Mr. Stetefeldt was lately in this city preparing drawings for the new furnace to be erected at the Manhatatn mill at Austin, and has now gone, we are informed, to superintend its erection.

Improved Awning.

In the matter of awnings, we have room for great improvemont in this city. No one can pass along Montgomery or other streets where they exist without being struck with their hideousness and general ineffectiveness; and in a rain, in many cases, they are worse than nothing, serving merely to collect the water in small dirty streams and pouring them down to the detriment of one's person and to the injury of one's temper.

Under these circumstances we feel ourselves fully justified in calling attention to and recommending a simple, neat and effective dovice, called the Miller & McClellan Awning, of which we give an illustration. Fig. 1 shows the awning extended, a portion of one of the side flaps being removed to show how the roller is supported at the middle, and Fig. 2 shows it rolled up. The framo consists of a pair of lazy tongs, which are shown extended in Fig. 1 and folded in Fig. 2. Each of these is provided at the inner end with a spiral spring, as at B (Fig. 1), which keeps the lazy tonge extended when the awning is used, and also aids in causing the cloth to wind up smoothly on the rollers when being rolled up. The outer end of the lazy tongs is formed into a hook, which is fastened to two boards, D, placed at right angles. These boards form the front part of the frame to which the awning is attached, and, moreover, protect the cloth when wound up on the roller, as shown in Fig. 2. The center of the main roller is supported on a pair of smaller rollers, F, which provent it from sagging. The side flaps run by means of rings on cords, which wind up on the roller and slide the rings together on the inner side thus folding the flaps. By means of the cord, C, the awning can readily be rolled up or extended, as desired.

By means of this device, no supporting parts are required, and the sidewalk in front of the store or house is left entirely unobstructed. The drop curtain always furnishes a sign, either up or down. When rolled up, the cloth on the roller is protected by the board from water, and the whole device is very neat and ornamental in appearance. It is not liable to get out of order, and can easily be worked by means of the cord.



MILLER & McCLELLAN'S PATENT AWNING.

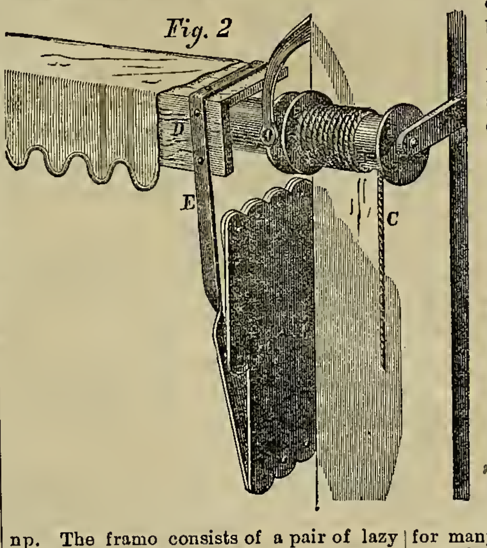


Fig. 2

This invention was patented in November, 1867, and has been assigned to J. B. Armstrong, President National Bank at Urbana, Ohio, to whom any communications concerning the purchase of rights or licenses should be addressed.

◆

An Old English Patent.—It is said that the following is the first patent ever granted in England for the preservation of food: "A. D. 1691, Oct. 7. No. 278 Porter Thomas and White John. A grant unto them of the sole use, exercise, and benefit of their new invencon of keeping and preserving by liquors *or otherwise* all sorts of fleshe, fowle and fish, and many other things, either in pieces or in whole bodies, at a cheaper rate, for many years in all clymates, without changing the nature, quality, taste, smell, or color thereof, as good, palatable, and wholesome, to be eaten and made use of for any intent and purpose whatsoever, as when first killed and put in such livuor; to hold and enjoy the same for 14 years, according to the statute."

◆

In several coal mines in the vicinity of Aux-la Chappelle safety lamps for burning petroleum have been introduced.

Qualifications of Patent Agents.

Considerable trouble has arisen, and considerable loss is being continually entailed on inventors, through the operations of unprincipled or unqualified patent agents. We hear every day of such cases, for which, however, there is no legal remedy. The only way to do is to go only to those agents who have attained a reputation, which is a guarantee both of their success and of their honesty. Dealing with agents who have no reputation nor well known connections is always dangerous; responsiblo parties only should be trusted. Our readers will find much that is interesting and valuable in the following extracts from the pamphlet of our London agent:

Here it may not be out of place to say a few words on the requisite qualifications of a patent agent. In the first place, he should be a person of studious habits and good education, because, in order to advise on the novelty of an invention, he must study very carefully those already patented; and in order to explain them clearly in the specification, it is evident that he must be able to commit his ideas to paper in a clear, intelligible manner. It is true, no man can be expected to understand perfectly all the subjects, mechanical and chemical, that may be brought before him; but if he has education, and industry to apply himself assiduously to what will be explained to him by the inventor, he will certainly have no difficulty in making himself sufficiently master of the subject to specify it intelligibly. I have made these few remarks as a guide to inventors, to enable them to judge of the requisite qualifications of a patent agent, as I am sorry to say I have known persons who have presumed to style themselves patent agents, civil engineers, etc., whose education was so limited that they could not put two consecutive sentences of the English language together correctly, and the extent of their engineering acquirements has been to drive a locomotive or feed a boiler. But perhaps the first and principal qualification required is honesty of intention. If the agent knows that the same identical invention has been previously secured, it is his duty to inform his client of the fact, before he allows him to spend any money upon it. I do not pretend to say that it is the duty of a patent agent to advise on the utility of an invention; that ought to be left to the judgment of the inventor himself;—indeed, I doubt if it be possible to advise inventors on that point; their enthusiasm is always so very great that it is almost impossible to persuade them that their inventions are impracticable; however, if the patent agent gives his opinion honestly, regardless of pecuniary considerations, he has done his duty; but I regret to say this is not always the case. We have had agents who have even received fees for patents to very large amounts, and used them for their own private purposes, without obtaining them; have become bankrupts, or passed through the Insolvent Court, and scheduled their clients for monies received for the special purpose of securing their inventions. I name these circumstances merely to caution inventors against consulting ignorant, unprincipled agents, as the law does not provide any remedy for those evils. Patent agents are not responsible to any one, except their clients, for neglect of duty,—it would be well if they were under the control of the Commissioner of Patents, as solicitors are under the Lord Chancellor, so that in case of neglect or misconduct they should be prevented from practising.

◆

The Pacific Business College offers many inducements to young men desiring a business education. The instructors are all persons of large business experience, and, therefore, well qualified to give students such teaching as will fit them for the practical operations of life. The situation is central, being at No. 27 Post street, in the Mechanics' Institute building.

SAPOINE

FRAGRANT SAPOINE FOR THE TEETH

THE GREAT MEDICAL DISCOVERY!

Dr. J. Walker's California

VINEGAR BITTERS.

More than 500,000 Persons

Bear testimony to their wonderful Curative Effects.

WHAT ARE THEY!

They are not a vile

FANCY DRINK,

Made of Poor Rum, Whiskey, Proof Spirits, and Refuse Liquor, doctored, spiced, and sweetened to please the taste, called "Tonics," "Appetizers," "Restorers," etc., that lead the tippler on to drunkenness and ruin, but are a true Medicine, made from the native roots and herbs of California, FREE FROM ALL ALCOHOLIC STIMULANTS. They are the GREAT BLOOD-PURIFIER AND LIFE-GIVING PRINCIPLE, a perfect Renovator and Invigorator of the System, carrying off all poisonous matter, and restoring the blood to a healthy condition No person can take these Bitters according to directions and remain long unwell.

They are a gentle Purgative as well as a Tonic, possessing, also, the peculiar merit of acting as a powerful agent in relieving Congestion or Inflammation of the Liver, and all the Visceral Organs. In Bilious, Remittent and Intermittent Fevers, these Bitters have no equal. For full directions, read carefully the circular around each bottle, printed in four languages—English, German, French and Spanish.

One Hundred Dollars will be given for an incurable case, provided the bones are not destroyed by mineral poisons or other means, and the vital organs wasted beyond the point of repair.

For Inflammatory and Chronic Rheumatism, and Gout, Dyspepsia or Indigestion, Bilious, Remittent and Intermittent Fevers, Diseases of the Blood, Liver, Kidneys and Bladder, these Bitters have been most successful. Such Diseases are caused by Vitiated Blood, which is generally produced by derangement of the Digestive Organs.

Cleanse the Vitiated Blood whenever you find its impurities bursting through the skin in Pimples, Eruptions or Sores; cleanse it when you find it obstructed and sluggish in the veins; cleanse it when it is foul, and your feelings will tell you when. Keep the Blood pure and the health of the system will follow.

J. WALKER, Proprietor.

FOR FEMALE COMPLAINTS, whether in young or old, married or single, at the dawn of womanhood or the turn of life, these Tonic Bitters display so decided an influence that a marked improvement is soon perceptible in the health of the patient. PIN TAPE, and other WORMS, lurking in the system of so many thousands, are effectually destroyed and removed. ☞ SEND FOR A CIRCULAR.

PACIFIC BUSINESS COLLEGE,

Mechanics' Institute, 27 Post Street,

BET. MONTGOMERY AND KEARNY, SAN FRANCISCO.

THE PIONEER AND ONLY BUSINESS COLLEGE

On the Pacific Coast where BOOK-KEEPING is taught as practiced in the Counting-room.

PENMANSHIP.

In this useful and very important branch we challenge competition.

PROF. SEREGNI

Has obtained First Premiums at all the Fairs on this coast where his Penmanship was exhibited, and was awarded the MEDAL at the Seventh Industrial Exhibition of the Mechanics' Institute in 1869 over all competitors. His success as a Teacher is unequalled.

TELEGRAPHING.

The only place in the city where Telegraphing is taught by an experienced Operator.

We cordially invite the public to call and examine the merits of the College. Our Institute is patronized by the youth of fifteen and the man of fifty, where they receive instruction in Single and Double Entry Book-Keeping, Commercial Arithmetic, Commission Jobbing, Business and Ornamental Penmanship, Commercial Correspondence, Actual Business, Merchandising, Banking, Importing Railroading, Steamboating, Mining, Real Estate, Brokerage and Exchange, Mechanical and Architectural Drawing, Telegraphy, Orthography, French, Spanish, Italian, German and English Grammar. No CLASS SYSTEM. Each student receives individual instruction. No Vacations.

Sessions Day and Evening.

12v20-12t VINSONHALER, JULIAN & CO.

Air—Daisy Deane.

'Twas down in the kitchen a turkey she was stuffing,
And trimming it with parsley fresh and green;
And the kettle on the stove was bubbling and singing,
When I first met my darling Daisy Deane,
None knew thee but to love thee, thou dear one of my heart,
Oh! thy cabbages were ever fresh and green;
Though the squash pie is gone, and stuffed hearts be eaten,
Still I love thee, my darling Daisy Deane.

While walking on the levee, she fell into the river,
And she floundered like a fish caught in a seine;
By the wetting she took cold and a racking cough soon followed,
It settled on the lungs of my darling Daisy Deane.
None knew thee, etc.

My bright flower seemed fading, like a rose that had fallen,
Though they dosed her with pills and kerosene;
For the doctors all agreed she'd die before the morrow,
Oh! my dear one, my darling Daisy Deane.
None knew thee, etc.

So down to the drug store I despondingly did wander,
To end my existence with a glass of glycerine;
But ALLEN'S PECTORAL BALSAM was placed within my grasp,
Just one bottle cured my darling Daisy Deane.
None knew thee, etc.

☞ Ask for ALLEN'S PECTORAL BALSAM, and see that the proprietor's signature (as below) is written across the wrapper in red ink. SOLD BY ALL DRUGGISTS AND GROCERS.

Depot—139 J Street, Sacramento.

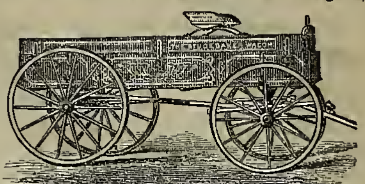
Crandall's Patent Spring Bed.

Manufactory, corner Front and M streets, SACRAMENTO COOLEY, HENRY & CO., Proprietors. These Spring Beds, wherever known, are universally acknowledged to be superior to any other in use. They are light, durable and elastic, and present no harborage for bugs or any other kind of vermin, thus being free from the objections so often urged against the ordinary spring beds. ☞ Orders received at our manufactory, or at our agency in San Francisco. 7v20-3m

The Celebrated Studebaker Wagon,



Manufactured by STUDEBAKER BROS. MANUFACTURING CO., South Bend, Indiana. WAGON DEALERS, there are nine reasons why you should buy the above Wagon:

FIRST.—They are made of the best selected INDIANA TIMBER, thoroughly seasoned under cover.

SECOND.—They are made by experienced mechanics.

THIRD.—The lightest running and most durable Wagon in the market.

FOURTH.—Their Thimble Skeins never break, while all others do.

FIFTH.—Most uniform and best proportioned Wagon in the market; any part of one will fit another, while other makes will not

SIXTH.—The only Wagon in which the SLOPE SHOULDER SPOKE is used; hence they have the best Wheel, which is actually the foundation of the Wagon, and should be carefully examined by persons buying.

SEVENTH.—They are sold only by responsible parties, and every Wagon is warranted to give entire satisfaction.

EIGHTH.—Because Teamsters will tell you they are the best Wagons, for all purposes, on the road.

NINTH.—Last, but not least, Studebaker Brothers are practical men, attend to their business personally, and do not entrust it entirely to foremen, as is generally the case in large factories; hence the superiority of their work over all others. Sold by

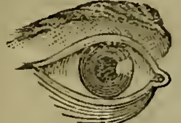
DR. ABORN,



Oculist, Aurist,

AND

CATARRH, THROAT

AND

Lung Physician.

No. 22 KEARNY STREET,

SAN FRANCISCO, CAL.

Testimonials from Well-known Citizens of California as evidence of his success.

Card from Charles N. Fox Esq., of the firm of Campbell, Fox & Campbell, Attorneys, 528 California Street.

I have for many months suffered from Catarrh, accompanied with unpleasant sensations and sounds in the ears. Recently I found my hearing impaired. and at once applied to Dr. Ahorn, No. 22 Kearny street, San Francisco. He improved my hearing almost instantaneously, and now, after being under his care six days only, I feel as if entirely cured, and my hearing is restored. CHARLES N. FOX.
San Francisco (Cal.), Jan, 10, 1870.

Card from S. O. Houghton, Esq., Attorney at Law.

I have been afflicted with severe nasal Catarrh for two years, which a few months since extended to my throat, producing a distressing cough, and seriously impairing my health generally. I have been under treatment hy Dr. Aborn, at 22 Kearny street. San Francisco, for about three weeks, and have been already greatly relieved—my cough has almost disappeared and my health greatly improved. By one application, Dr. Ahorn relieved me of a very severe neuralgic pain, and with four applications it was entirely cured. S. O. HOUGHTON.
San Jose (Cal,), Nov. 22, 1869.

From Hon. Jas. A. Johnson, M. C., California.

To whom it may Concern.—Having heen a sufferer with Catarrh and a severe bronchial affection for more than seven years, and having found great relief hy submitting myself to Dr. Aborn's treatment for a few days only, I take pleasure in saying Dr. Aborn, with his new and improved instruments for local applications to the lungs, air passages, eyes and ears, should encourage all who are affected in those parts to cherish a lively hope that they may find quick and permanent relief. Very truly, JAMES A. JOHNSON, M. C., California.

A Wonderful Cure.

Having heen afflicted for over twenty years with a disease in the left nostril, which has been called by different names—cancer, scrofula and ozena—different physicians have tried their skill in attempting its cure, hut without success. It has rendered me incapable of labor for the last two years. Since the beginning of June last I have heen in the Sacramento hospital reduced to a mere skeleton. On the 23d of November I left the hospital, and since the 26th have heen under the treatment of Dr. Aborn in this city, and the disease is already nearly cured, and my strength and general health very much improved, and I have full confidence of a perfect cure. Already I have gained many pounds in weight, and look and feel like another person. The success of Dr. Aborn's treatment in my case should be sufficient to encourage all who have chronic diseasesto make another trial for that good prize—health.
WILLIAM BEARDSLEE.
Pacific House, San Francisco, Dec. 13, 1869.

Another Remarkable Cure.

For the benefit of the afflicted and as an act of justice to the skill of Dr. Aborn, I make the following statement: For about two years I was seriously afflicted with a bronchial affection. I had a distressing cough, difficulty of breathing, expectoration, night sweats, and was losing flesh very rapidly. I was treated by five physicians without any benefit, but continued to grow worse, and was finally advised hy them to leave the city, as in their opinions I could not be cured in this climate; hut my business relations were such as to preclude a change of climate, although my health was declining so fast that I could not have lived long without relief. Two months ago, when Dr. Ahorn arrived, I read his publications and the testimonials of his remarkable cures, which led me to believe that there must he merit in his treatment. So I placed myself under his care, and it is with great pleasure that I am able to say that he has cured me of those distressing and dangerous bronchial affections; also, the night sweats, cough, etc. I was unable to attend to business since April last, until after being under Dr. Aborn's treatment for one week. My improvement was so rapid that in one week's time I was able to resume my business, and I have continued to gain ever since so rapidly that even my friends are surprised at the remarkable results of his treatment.

The large majority of United States and Foreign Patents granted to inventors on the Pacific coast during the past few years, have been obtained through the agency of Dewey & Co., publishers of the Scientific Press. Established in the year 1860, we have an extensive patent library, with full record of cases on this coast, and can give the best and most reliable advice as to the patentability of new inventions.

Greatest Discovery Ever Made.

MR. J. W. MAC, while a resident in New Zealand, was so afflicted with the RHEUMATISM, that for years he was completely crippled and unable to attend to business. The symptoms were of the worst type—knees painful and swollen, with sinews contracted; shoulder, arm and hand rendered useless, and accompanied with continued excruciating pain. While in this state of suffering, he got acquainted with a native of the country, who applied to the parts affected a composition spread on coarse canvas, the properties of which were so wonderful that in a short time all the pain left him, the swelling disappeared, his sinews relieved, and he was able to resume his usual avocations. So effectual has heen the remedy, that to this day he has enjoyed perfect health, without the slightest return of his former complaint. Knowing the great blessing such a remedy would he to those afflicted with this painful disease, he with great difficulty and expense ohtained the secret of preparing the Plaster; and during the many years MR. MAC has applied these Plasters in New Zealand, Tasmania, New South Wales, and this city, their effect has heen marvelous, giving to the most painful and long-standing cases sure and certain relief. The most incredulous will be convinced hy referring to these persons: B. W. Owens, 405 Front street; F. B. Alderson, Traveling Agent for Dewey & Co., 414 Clay street; James Flynn, 519 Mission street: Michael Gorman, No. 6 Front street; Mrs. W. S Wright—late of Gilmore House—518 Folsom street, now agent at Virginia City; E. Shenley, corner Montgomery and Filbert streets· W. M. McLeod, Depository merican Tract Society, 557 Market street, and a host of others, who all bear testimony to the unparalleled healing powers of J. W. MAC'S (rightly termed Magic) Plasters, for the cure of Rheumatism, Gout, Weak Loins, Tender Feet and Neuralgia. J. W. MAC may be consulted at his office, rooms Nos. 34, 35 and 36, 128 Kearny street, San Francisco, between the hours of 9 to 12 A. M., 2 to 4 P. M. and 7 to 9 P. M.

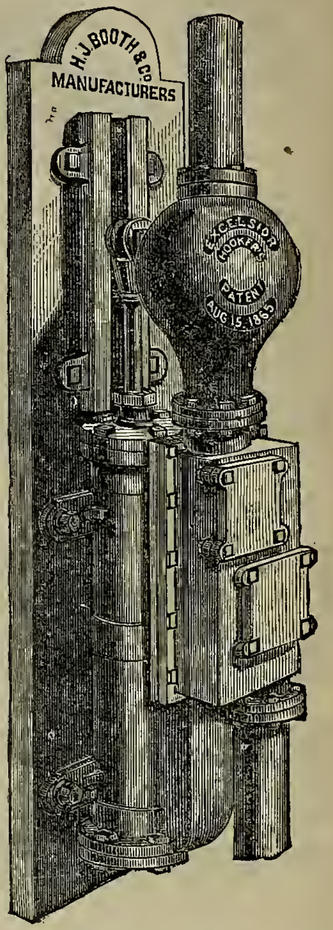
NO TROUBLE IT GIVES
FOR DOMESTIC USE
FIRES, OR IRRIGATING PURPOSES
IT IS FAR SUPERIOR to any OTHER PUMP.
STRONG
SUPERIOR MAKE
DURABLE AND PERFECT
AND SUBSTANTIAL IN EVERY RESPECT.



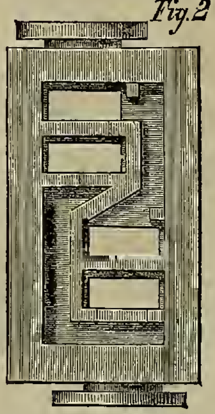


Fig.2

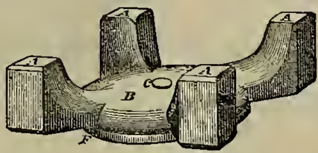
VALVE BOX.



VALVE.

We call the especial attention of all Millwrights, Miners and Farmers to this very superior Force Pump. It is more simply constructed, more durable, and has larger and more direct ports for receiving and discharging water, and warranted to furnish more water than any other pumps of equal caliber. It has Poppet Valves, which can not be wrongly placed in the Pump. The Fair of the Mechanics' Institute, held in the city of San Francisco, awarded the owners of this Pump, FOR ITS SUPERIORITY, A FIRST PREMIUM AND SILVER MEDAL. Suitable for DEEP WELLS, Factories, Mining, Breweries, Sugar Refineries, Tanneries, Railroad Purposes, Drainage, Irrigation, etc. As the above Pumps are already in use in the principal Sugar Refineries, Factories, Rolling Mills and Gardens in this city, reference may be had where they are working. ☞ See circular for particulars.

General Agents.—MESSRS. BRITTAN, HOLBROOK & CO., 111 and 113 California street and 17 and 19 Davis street, are Agents for the sale of the Excelsior Pump, who make liberal discount to the trade. H. J. BOOTH & CO., Union Iron Works, First Street, corner of Mission, San Francisco, who manufacture and have the sale of the Excelsior Pump.

V. CUSHING, Proprietor, San Francisco.

☞ We have BRASS-LINED, BRASS PISTON and BRASS VALVE PUMPS, at greatly reduced prices. Also STEAM PUMPS. ☜

THE EQUALIZING INSTITUTE.

SOMETHING NEW.

The Equalizer,

A TRUE GUIDE

—TO—

HEALTH.

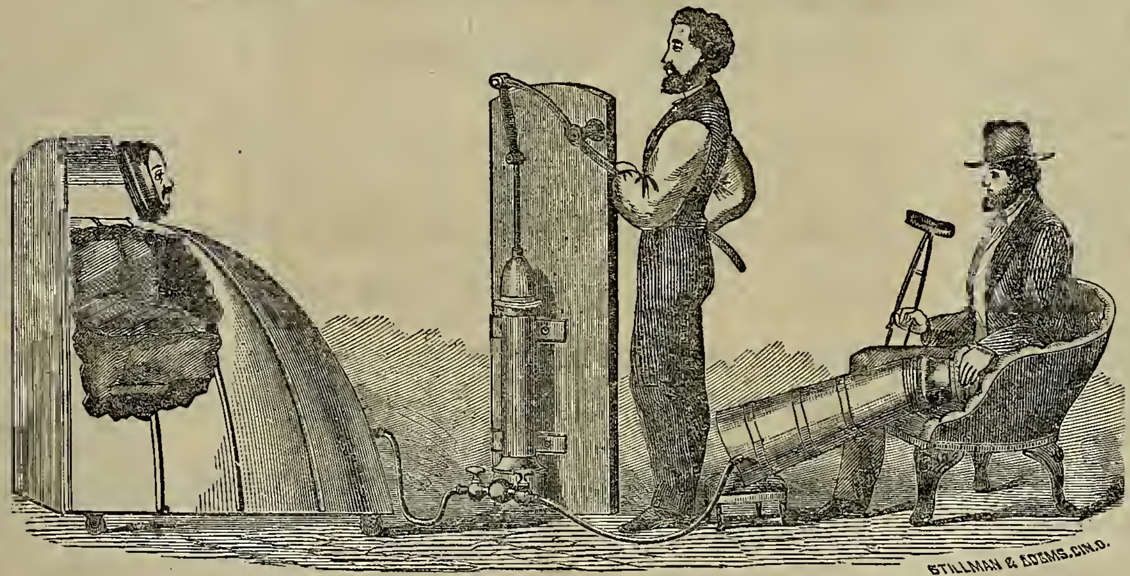
CURES

All Chronic Diseases

—BY—

VACUUM.

This treatment causes a thorough circulation of the blood throughout the system, creates new life, restores the GENERATIVE ORGANS, and reinstates perfect health.



STILLMAN & EDEMS.CIN.O.

The Following Diseases

CAN BE CURED

By this System:

Paralysis, Nervous Debility, Neuralgia, Dyspepsia, Asthma, Curvature of the Spine, and other Spinal Affections; Sciatica, Palsy, St. Vitus' Dance, and Derangement of the Mind; Pro Lapsus Uteri, Obstructed Menstruation, with all their concomitant diseases, Impotence, and all kinds of Weakness of the Generative Organs, can be cured. It breaks up congestion and inflammation in every part of the system.

All those treated with any of the above diseases can be speedily cured by application of the Equalizer.

Ladies will be treated by a competent Female Physician, who graduated in a New York Institute.

OUR BREAST GLASS

Is not simply an elevator of the breast for ornamental purposes, though it is true it will increase the size of the breast to any extent desired; but this is the least of the advantages derived from its use. For the health of both mother and child, every mother should nurse her own babe. The benefit derived from the application of this Glass will enable her to do so with pleasure.

CONSULTATIONS

Can be had with the undersigned at all hours at the office of the Equalizer,

No. 650 Howard Street,

SAN FRANCISCO.

RADICAL CURE OF PARALYSIS.

P. Winsdor, having suffered severely from four sun strokes, in the last two years from four strokes of total Paralysis and loss of speech, had recourse to the Equalizer as a treatment for same, and by means of the Equalizer was perfectly cured in the astonishing short period of four months, and as a proof of the above he can be seen at the Equalizing Institute, Howard street.

SAN FRANCISCO, February 17th, 1870.

P. Winsdor—Dear Sir:—I am 70 years old, have been Paralyzed two years on my right side. After using the Equalizer one month I find myself much improved. My leg, which would drag the ground when walking, now comes up as usual; my right arm, which was drawn round in front, now hangs by my side as formerly; my fingers, which had lost their sense of feeling, have been greatly improved, so that I can feel the smallest article. I was also troubled with the Rheumatism in my left arm and shoulder, which has been entirely removed during the month's operation. In many other respects I am much improved.

Yours, Respectfully,

[Signed] DAVID COLLINS,
208 First street.

[The above letter is in Mr. D. Collins' own handwriting, and can be seen at the Institute.]

SAN FRANCISCO, February 18th, 1870.

P. Winsdor—Dear Sir:—I am 32 years old, and have been Paralyzed in my right leg for three years, during which time I could not walk without a crutch and cane, but after a treatment of four months by the Equalizer, am able to walk quite comfortably without any assistance, and strongly recommend the Equalizer as a cure for the Paralysis. Yours Respectfully,

AARON MARKS,
Auction Store, corner of California and Kearny streets, San Francisco.

SAN FRANCISCO, February 17th, 1870.

Dear Sir:—In January, 1870, I suffered severely from Rheumatism, so much so as to prevent me from practicing in my profession as a Dentist. I tried the Equalizer as a remedy, and in twenty minutes after the first application experienced great relief; four more applications cured me perfectly, and I fully recommend the Equalizer as a certain and rapid cure for the Rheumatism.

Yours Respectfully,
DR. J. W. WINTER, Dentist,
No. 405 Kearny street.

N. B.—Ladies desirous of being treated by the Equalizer will be attended on by a Female Physician, who graduated at a New York Institute, and can obtain first class lodgings at moderate prices at the Institute. Those who wish to be treated at their residence can be accommodated.

Proprietor of the Equalizing Institute,

PHINEAS WINDSOR, E. C.

Illustrate your Inventions

In the Scientific Press,

An illustrated journal of Mining, Farming, Mechanic Arts and Industries on the Pacific Coast. It costs no more for a superior engraving by our experienced artists than is usually charged for a less perfect picture. If you wish to introduce a new invention properly before the public, the first steps in so doing are important ones. A full description and correct representation in the Press will go further and prove more quickly effective than any other means.

The fact that an illustration is admitted into our columns, guarantees the invention important consideration in the minds of thousands of the most intelligent readers—at home and abroad—who would not notice it so favorably or so thoroughly, if at all, when presented through an unreliable medium or indifferent source.

The model of an invention sent to us is sufficient for making a good engraving. Sometimes a photographic view is sufficient; but it is always best accompanied with drawings or a copy of the patent. A first-class illustration has proved to be one of the best and cheapest means of obtaining purchasers for a good machine or a valuable patent.

Cuts ordered for illustration are the property of the inventor who pays for them, and can generally be used for circulars, pamphlets, books, or other newspapers. The engravings to be seen in each issue of the Scientific Press are a fair sample of the work of the artists who can always be found in our office.

Important to Assayers.

Crucibles.

The Patent Plumbago Crucible Co.

Manufacturers of all kinds of
Melting Pots, Portable Furnaces,
CRUCIBLES, and other fire-standing Goods,
Battersea Works, London.

THE MORGAN PATENT CRUCIBLES have uniform quality, never crack, withstand the greatest heat without danger; heats more rapidly than any other; change of temperature has no effect on them; stand on the average forty to fifty pourings.

CERTIFICATES:

United States Branch Mint, San Francisco, Cal., March 12, 1869—Messrs. A. S. Hallidie & Co., Agents Morgan Crucible:—I have carefully tested the Morgan Patent Plumbago Crucibles purchased from you for the U. S. B. Mint, and cheerfully certify to their superiority and economy over all other Crucibles used by and under me. They are fully what you represent them, and I shall continue to use them in preference to any other. J. M. ECKFELDT,
Melter and Refiner, U. S. B. Mint.

Eagle Brass Foundry, 206 Fremont street, San Francisco 12th March, 1869—Messrs. A. S. Hallidie & Co., 519 Front street—Gentlemen:—We have used and tested the Morgan Patent Plumbago Crucible, for which you are agents, and pronounce them superior to and cheaper than any Crucible used by us heretofore. GREENBERG & MOORE.

Messrs. A. S. Hallidie & Co :—We have thoroughly and severely tested in every way the Morgan Patent Plumbago Crucible obtained by us from you, and find them superior to any we have yet tried, although we have used every pot obtainable in this market, we have none equal to the above, and concede your claims for them. We think they will average 45 pourings of brass.
GALLAGHER, WEED & CO.,
California Brass Works, 125 Front street, San Francisco.

Assay Office of H. Harris, Silver City, Nevada, April 24, 1869—Messrs A. S Hallidie & Co.—Gents.:—I received from you three Crucibles of the Morgan make, which I have used since their arrival, and tested by constant use. Since 1847, when in the New Orleans Mint, I have always preferred the Crucible of Dixon's make over Adus, Gautier, and Taunton, Mass. Yours I find to be not alone of more finished make, but to stand double or treble the work of Dixon's Crucibles. The No. 12—the smallest sent—has stood so far 32 meltings, and is as good and sound as when received. Your Crucibles do not scale off like others; and as they are forty per cent. cheaper, I do not see why they should not be preferred by all assayers on account of durability and cheapness. Yours respectfully, H. HARRIS.

This book is bound in cloth, and embraces 122 pages. The illustrations are plain, and each figure is clearly described on the page opposite to it. It is a low-priced book for its kind, and there are few persons who have to do with machinery, or are interested in understanding the science and principles of motion, who will not be benefitted and satisfied by its purchase.

A liberal discount made to the trade. Single copies, $1—sent postage free. Address orders,

DEWEY & CO.,
Patent Agents, San Francisco.

The Scientific Press,

Devoted to Scientific and Mechanical Progress, Mining, Farming and Mechanic Arts, contains more valuable Reading Matter than any other weekly journal west of the Rocky Mountains. It is the best printed and only finely-illustrated paper on the Coast. Its articles are able, timely and reliable, and written in a more interesting and easily comprehensive style than scientific papers in general. Now in its twentieth volume, it is printed on superior paper, containing sixteen pages, equal in size to the first-class journals of the Atlantic States and Europe. All our best citizens are interested in the new discoveries in the development and progress of the three great industrial pursuits named above, which are closely allied on this coast, and are jointly represented in the Press, rendering it a popular and influential journal with all industrial readers. Subscriptions reduced to $4 a year, Jan. 1, 1870.

To Inventors on the Pacific Coast.

Our U. S. and Foreign Patent Agency presents many and important advantages as a Home Agency over all others by reasons of long establishment, great experience, thorough system, and intimate acquaintance with the subjects of inventions in our own community. All worthy inventions patented through our Agency will have the benefit of an illustration or a description in the Scientific Press. We transact every branch of Patent business, and obtain Patents in *all civilized countries.* The large majority of U. S. and Foreign Patents granted to inventors on the Pacific Coast have been obtained through our Agency. We can give the best and most *reliable* advice as to the patentability of new inventions. Advice and Circulars free. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior.

Engraving on Wood, of every kind, for illustrating machinery, buildings, trade circulars, labels, plain or in colors, designed and cut in the best style of the art by experts in our own office. Also, engraving on metals.

SPORTING,

MINING,

And BLASTING

POWDER,

Of SUPERIOR QUALITY, FRESH FROM THE MILLS. It being constantly received and transported into the interior, is delivered to the consumer within a few days of the time of its manufacture, and is in every way superior to any other Powder in Market.

We have been awarded successively

Three Gold Medals

By the MECHANICS' INSTITUTE and the STATE AGRICULTURAL SOCIETY for the superiority of our products over all others.

We also call attention to our

HERCULES POWDER,

Which combines all the force of other strong explosives now in use, and the lifting force of the best blasting powder, thus making it vastly superior to any other compound now in use.

A circular containing a full description of this Powder can be obtained on application to our Office.

"Live and Let Live,"

Is a good old adage, and we shall adopt it as onr own. We do not pretend to do work at "less than cost," as some peopla advertisa to do; hut we do claim to do all kinds of printing as cheap as it can ho done on this Coast—and wa helieve as cheap as it is DONE in Chicago. Customers, in the country or city, are invited to call in person at our office, or send their orders hy mail or express, and thoy will be fairly dealt with.

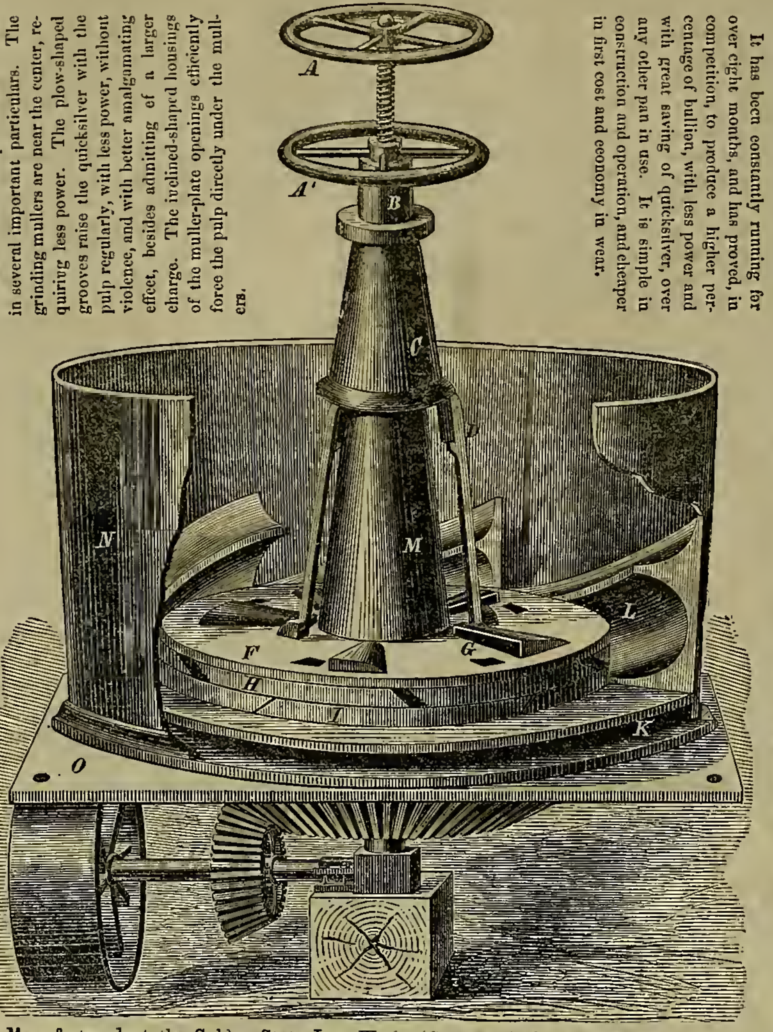
SPAULDING & BARTO.

Scientific Press Office,
414 Clay Street.

STEVENSON'S PATENT MOULD BOARD AMALGAMATING PAN.

This Pan is far superior to all others in several important particulars. The grinding mullers are near the center, requiring less power. The plow-shaped grooves raise the quicksilver with the pulp regularly, with less power, without violence, and with better amalgamating effect, besides admitting of a larger charge. The inclined-shaped housings of the muller-plate openings efficiently force the pulp directly under the mullers.

It has been constantly running for over eight months, and has proved, in competition, to produce a higher percentage of bullion, with less power and with great saving of quicksilver, over any other pan in use. It is simple in construction and operation, and cheaper in first cost and economy in wear.



Manufactured at the Golden State Iron Works (Co-operative), 19 First street, S. F.,

Where it can he examined and further particulars he learned; or persons may apply to the inventor and patentee, Mr. C. C. STEVENSON, at the Douglas Mill, Gold Hill, State of Nevada, where the Pans have long been in constant operation. 15v20-1mr,1amtf

Valuable Ranch For Sale

NEAR HEALDSBURG.—In the fine valley of Russian River three and one-half miles south of Healdsburg, on the west side of the river, is now offered for sale a splendid farm of 260 acres of land (minus eight by twelve rods occupied by a good school house), 100 of which is of the richest of Russian River bottom, eighty acres of which is now in small grain, not surpassed by any in the State, five acres in bearing orchard of the choicest selections, fifteen acres plowed for corn, and the remaining 160 acres is rich, yet rolling timbered land, five acres vineyard of choice selection. The Dwelling has ten rooms, not yet finished, and supplied by a good spring of excellent water, and cost above $12,000. The barns and outhouses are in excellent condition. The title is "Fitch Grant," which is undisputed. The entire farm is inclosed, about half with a picket and half with a rail fence, both in good condition. The farming utensils which are offered with or in the sale of the farm, are as follows: Five plows, two harrows, two cultivators, one Buckeye reaper; also twenty head of hogs. There are 200 redwood trees within about five miles of the premises, and wood enough to supply all the demands of the place. It is well known by all parties who have resided for any length of time on this coast, that the climate of Russian River Valley is lovely, healthy and not surpassed by that of any other place in the United States.

The reason for selling is, that the owner is getting too old to cultivate a farm, and wishes to close up his business and live more retired. The place is a rare bargain at tha price asked for it.

For further particulars, apply to McLean & Hardy, Real Estate Agents, No. 338 Montgomery street, southeast corner of California street, San Francisco. 11v20

Reading for the Hour.

Where Fat and Flesh Come From.

They come from the earth and the atmosphere, collected by vegetation. Grass contains flesh; so does grain. The animal system puts it on from these. Vegetation then is the medium through which the animal world exists; it can exist in no other way. When grass or grain is eaten, the flesh constituents are retained in the system; so also the fatty substance—that is, the starch and sugar, from which fat is made. Some grains have more flesh than others; so of the qualities that make fat. In a hundred parts of wheat, according to Piesse, are ten pounds of flesh; in a hundred parts of oatmeal, nearly double that amount. Hence oats are better for horses, on account of their flesh-forming principle, rather than fat, as muscle is what a horse wants. For fattening purposes, however, corn and other grains are better.

When flesh itself is eaten, the system but appropriates what is already formed, but would as readily take it from vegetables as from flour. The flesh-making-principle—or the flesh itself, in its constituents—goes to form cheese in the dairy; the starch, etc., butter. Hence it is that some people assert that cream has little influence in cheese, farther than to enrich it; for cheese and butter are entirely distinct. The same kind of food is equally good for the production of either. This is a point of considerable interest, and is not yet fully explained—indeed, is yet in its infancy. And a plant in its different stages of growth has a different effect. The fat of the plant is held in reserve for the seed; nothing is wasted in leaves, wood, etc.; the precious seed must have it. Hence when this takes place, the stalk is comparatively worthless to what it is prior to the change. And the fat cannot be appropriated so well in the seed as when it is diffused through the stalk. Tender herbage, therefore, is the best; and when secured before the direction of the oil takes place, so much the better will be the hay.
—*Colman's Rural World.*

Water On the Stove.

It is quite a general practice to keep a dish of water on a stove to prevent the atmosphere from "getting too dry," as it is called, a condition which, it is thought, is liable to produce the headache. The idea is an erroneous one and the practice is bad. The bad air which is felt in an illy-ventilated room warmed by a stove, arises from the escaping of carbonic acid gas into the room. If the stove is very hot the gas will pass through the iron walls of the stove. When there is a bad draft it will find its way out through the joints. The chief cause of trouble arises from bad ventilation. *Hall's Journal of Health*, good authority on such matters, says:

"By filling the air with steam, it is rendered just as much less nutritious to the lungs and blood as if filled to that extent with the fumes of a dead carcass. This damp atmosphere exerts something of a steaming process on the skin, and thus renders the person extremely liable to take cold as soon as he goes into the open air. We want the air of a stove-room ventilated, changed for pure air without, not filled with the vapor of water. The only way yet known to improve the air of any room warmed by artificial heat is to open a door or window, from time to time, as while the family are at table eating regular meals."

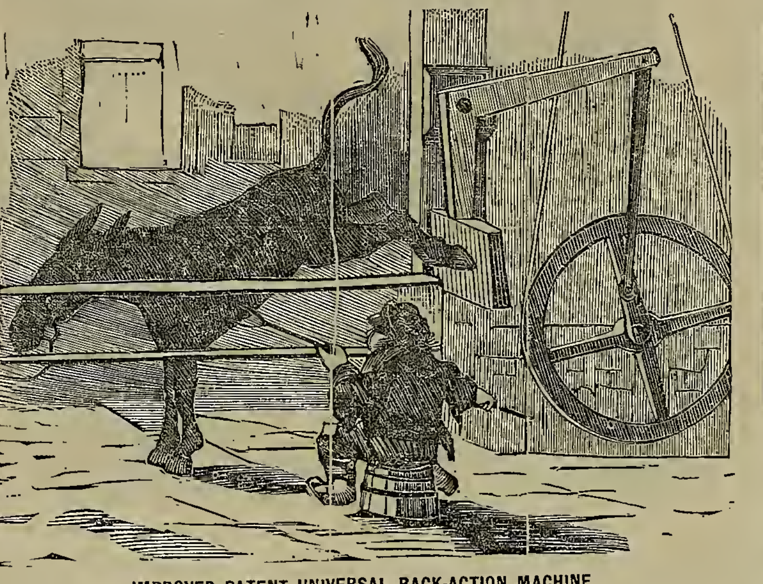
Shrinking of Timber.—Oak and some other kinds of timber will shrink every time it is dressed. Wagon spokes may be blocked out and laid out in a dry, warm shop for two years, and then if fitted and driven immediately into the hub they will shrink in a few days so as to be loose. They should be fitted and left to dry and shrink before being driven. Much of the agricultural machinery made of oak and ash soon works loose, notwithstanding the timber was seasoned, because the tenons were not permitted to season after being fitted for the mortice. The tenons should be made a little full, and left to dry a few days.—*Manufacturer and Builder.*

The revenue of Newfoundland for 1869 amounts to $668,000. This is the largest ever received, the fisheries being unusually productive, and the importations above the average. Some idea of the resources of the country may be formed from the fact that in 1867 the value of the exports (fish and oil) was $5,471,051, besides $256,000 worth of ores. The quantity of dry codfish exported in 1868 was 1,066,215 quintals, (a quintal is 112 pounds' weight) 389,672 seal-skins, and 5,142 tons of seal oil.

The Last Patent.

We have before remarked on the ingenuity of the great American race in the useful adaptation of things. Our remarks have received an apt illustration in a patent lately applied for by an intelligent Yankee, which is so much to the point that we cannot refrain from giving it for the benefit of our readers. We are only sorry that we cannot give the name of the inventor, but this any curious person can obtain by applying to the *Rural New-Yorker*, which is our veracious authority for the illustration.

Inventors will please notice that it is the back action which is here patented, and that the particular arrangement of the machinery is a matter of secondary importance. The nativity of the individual with the pitchfork is not essential, but the patentee thinks he can always furnish persons of the proper temperament for this work, and we doubt not his capability in this respect. As a matter of precaution it is well to have the head knocked out of the cask, which is used as a stool.



IMPROVED PATENT UNIVERSAL BACK-ACTION MACHINE.

The wide adaptability of the patent will be readily understood by the reader, and we predict for it a general introduction. Besides its material usefulness, it will tend to ameliorate greatly the moral condition of mule drivers, by enabling them to vent their spleen in a manner which, while relieving their minds, will at the same time produce some useful result. It should be in every household—if not there already.

Persons desirous of obtaining further information or instruction with regard to the best manner of proceeding with the animal, or of purchasing State or county rights, may apply to themselves, or as above.

How to Make Molasses Candy.—Take a quart of syrup, two pounds of good brown sugar (or one of brown and one of white). Boil over a slow fire in a brass or porcelain kettle. Try it by putting some in a cup of cold water; when it is brittle, it has boiled enough. Then take it out into a buttered pan. Put it on ice, or in a cool place. When the edge is cold the center will be warm; then bring it in. Have a buttered board to work on. While you are working it is the time to flavor it; work it till it is all of the same degree of heat. Pull it on a hook until it is white. Now handle it lightly, or it will be dark and hard. Pull it out in a long string before you take it from the hook. Put it on the table, and when cold, break it into such sized sticks as you please. You will have to work fast, or it will be dark and hard. Candy made this way is equal to sugar candy.

The phosphate of lime beds, near Charleston, S. C., are from eighteen inches to two feet thick, and the phosphate is worth six dollars a ton in Charleston. It is now proposed to build a canal two miles and a quarter long from the beds to Ashley river, so that the transportation of the material to the city may be rendered easier.

A Recent Invasion into France.

There is found in tropical regions, in Asia, Africa, America and Europe, a formidable insect called the white ant—the *termites* of naturalists. The most wonderful species is that found in the interior of Africa. These insects build up their habitations in the shape of a cluster of rounded cones or spires, with the highest in the center, often twenty feet high and with galleries below the surface to the same depth. The walls are of clay, and nearly as hard as stone. They live on vegetable food, but they delight especially in woody fibers; yet, when pressed with hunger, they devour almost anything in their way. They feed on the core of things, leaving always a thin shell. From their large numbers, their voracity and their way of working, they form a most formidable enemy to man and his works.

Some years since, says a writer in *Putnam's Magazine*, a few of these terrible insects were discovered at La Rochelle, on the eastern coast of France, undoubtedly imported from a tropical port. These have not only survived the cold winters, but have increased in numbers. The efforts to exterminate them have been unsuccessful, and their ravages are already most serious. They seized the public buildings, like other invaders, and made their headquarters at the Hotel of the Prefect. The conquest has been complete, and from the attics to the cellars they are masters of the position. The ceiling of a bedroom was repaired; the day after the workmen left, covered galleries, made by the enemy, were discovered dropping from the ceiling like stalactites. Similar galleries were found in the cellars; others running along the walls beneath the plaster were traced from the foundation to the roof. Occasionally horizontal galleries, like suspension bridges, are thrown out to reach some desired object. Trees in the garden, apparently sound, proved to be entirely gutted to the branches. The stakes of fences were devoured in the same way. A large beam was so entirely eaten away that nothing remains but a thin outer shell. The legs of tables, the sides of boxes, were ruined in like manner. One day a document from the public archives was wanted. The box containing it was opened; all looked as usual; piles of neatly folded papers appeared undisturbed in regular order within; but the moment a hand was laid on the outer sheet the whole pile crumbled to dust. And such proved the case with other boxes where the public archives had been stored. No wonder the good people are seriously alarmed. Corrosive sublimate is said to be the only protection for any wooden substance, and one which is not always successful.

Continental Life Insurance Co., 302 Montgomery street, corner of Pine.

Eminent Merchants and Bankers.—"The Merchants' and Bankers' Almanac for 1870" is now ready for distribution, containing the names of six thousand bankers in the United States, Canada, and Foreign Countries. Monthly Prices of Cotton, Wool, Corn, Sugar, Molasses, Tobacco, Coffee, Wheat, Oats, Rye, and Flour, for forty-three years (1825—1869,) and crops in 1868. Names of New Marine, Fire, and Life Insurance Companies, in each State. Daily price of Gold, in New York, from January, 1864, to December, 1869. Progress of Railroads in the United States and in each State, from 1835 to 1869, number of miles, cost, etc. The Cotton Crop of the United States, 1860 to 1869,—annual product of each State, export, consumption, etc. The monthly prices of eighty staple articles, at New York, year 1869. Alphabetical list of 2,000 Cashiers, in the United States. Lowest and highest prices of leadin Government, State, Bank and Railroad Shares, Bonds, etc.—years 1868–9. The Clearing House, New York, annual exchanges, 1854—1869. Table of income and expenditure of the U. S. Government. Imports, Revenue, Public Debt, etc., of Great Britain, 15 years. Price, two dollars. This volume is enriched by the addition of engravings of new banking houses, which will serve the purpose of models for those who propose to build. An illustrated edition of this Almanac has been printed, containing in additon to all the matters in the plain edition, thirty wood-cuts to illustrate the banks of N. Y., and portraits (engraved on steel) of eminent Merchants and Bankers. These engravings cost several thousand dollars, being executed in the best style by the American Bank-note Co., and include the heads of John Jacob Astor, Wm. B. Astor, Peter Cooper, E. Corning, Robert Fulton, Albert Gallatin, Henry Grinnell, Philip Hone, Walter R. Jones, James Gore King, C. W. Lawrence, David Leavitt, Robert L. Stevens, Thomas Tileston, and C. Vanderbilt of New York; William Appleton, Jonas Chickering, Peter C. Brooks, N. Bowditch, Abbot Lawrence, George Peabody, Robert G. Shaw, T. H. Perkins, and T. Douse, of Massachusetts; Stephen Girard, N. Biddle, Thomas P. Cope, John Grigg, Robert Morris, of Pennsylvania; also the heads of N. Longworth, Jacob Baker, W. F. Harnden, Samuel Slater, De Medici, and Dadabhoy. The illustrated edition is interleaved with writing paper, and contains thirty engravings of the banks of New York. Price, five dollars.

Published at the office of the Banker's Magazine, New York. P. O. Box 4574.

☞ Maravilla Cocoa. *For Breakfast.*—The *Globe* says: "Various importers and manufacturers have attempted to attain a reputation for their prepared Cocoas, but we doubt whether any thorough success has been achieved until Messrs. Taylor Brothers discovered the extraordinary qualities of 'Maravilla' Cocoa. Adapting their perfect system of preparation to this finest of all species of the Theobroma they have produced an article which supersedes every other Cocoa in the market. Entire solubility, a delicate aroma, and a rare concentration of the purest elements of nutrition, distinguish the Maravilla Cocoa above all others. For homœpaths and invalids we could not recommend a more agreeable or valuable beverage." Sold in packets only by all Grocers, of whom also may be had Taylor Brothers Original Homœopathic Cocoa and Soluble Chocolate. Steam Mills Brick Lane, London. 5v20-1y

Important Invention.—The best drink, not containing alcoholic stimulants, yet answering all the requirements, is that made by Kenyon, Gass & Co., and known as Champagne Mead. It is recommended by the medical fraternity of this city, and should be the exclusive drink of all temperance men. It contains no injurious acids. *

A Valuable Book for Inventors and Artisans.—Dewey & Co., publishers of the Scientific Press and Patent Agents, have just issued a neat little volume of over five hundred well executed cuts of the principal mechanical movements known. These useful representations of the various appliances of power are printed side by side with explanatory notes, which makes the subject clear to every reader. Such a book should be in the hands of every mechanic, and form part of every public school library. It is a handy book, and cheap enough for every farm, shop and factory. Sent to any address from the Scientific Press office, postpaid, for $1.—*New Age.*

To Miners, Millmen and Metallurgists. Kustel's new work on the Concentration of all kinds of Ores, and the Chlorination Process, for Gold-bearing Sulphurets, Arseniurets, and Gold and Silver Ores generally, is the best and most complete work issued. It contains 120 diagrams, illustrating machinery, etc., which alone are of the greatest value. Price, $7.50, postage paid. Published by Dewey & Co., publishers of the Scientific Press, San Francisco.

Layres' Elements of Composition.—This is a valuable book of 166 pages, containing plain and simple instructions in the art of composition. It should be read by all intelligent persons who desire to write or speak English correctly or eloquently. Printed and sold by Dewey & Co., Scientific Press Office.

There is no light equal to the Portable Gas Light, for Families or Business places, in town or country; at one-fourth the cost of coal gas, and cheaper than coal oil. The Lamps and County Rights are for sale at P. J. PHILLIPS & CO., 650 Market street. No trimming wicks or breaking chimneys. Everybody should see and have them. 19v20

Treatment of Rebellious Silver Ores, by Charles H. Aaron—a pamphlet of eight pages of concise reading, of practical value to parties interested in the subject. Printed and sold by Dewey & Co., at this office, for 25 cents, post paid.

Philo B. Fox is requested to report list of subscribers taken for the Scientific Press to date. His agency (for Napa, Sonoma and Mendocino counties) is hereby revoked. His receipts, given previous to this notice, will be acknowledged at this office.
DEWEY & CO., Publishers.
San Francisco, April 28, 1870.

C. Muller, optician, 205 Montgomery, stands first in his profession, and all those who suffer from defective eye-sight should apply to him. *

Mason's Bread of Life, for Dyspeptics, Coughs, Colds, Asthma, Catarrh, Hoarseness, Bronchitis and Sore Throat. Price, 25 cents per box. These lozenges are free from all dangerous properties. Compounded and put up by Dr. J. H. Mason, 750 Howard st. 16v20-3m

Business Fortunes are often made easily, quickly and legitimately by Patent Rights. We advise both sellers and purchasers to patronize reliable agents only. Webster & Co., patent brokers, No. 314 Bush street, San Francisco, are one of the most honest, reliable firms in the United States. *

Photography.—For Cabinet Photographs, or Enameled Cards, of the very best quality, you must go to the NEW YORK GALLERY, Nos. 25 and 27 Third street, San Francisco. Every picture warranted to give satisfaction.
10v18 6m B. F. Howland.

Thomas O'Neil, Ornamental Glass Cutter, No. 10 Stevenson street, up stairs. Stained, Ground and Ornamental Cut Glass to order on reasonable terms. 14v20

Microscopes for Scientific Investigation and Educational Purposes. Price list sent free. T. H. McAllister, Optician, 49 Nassau street, New York. 15v20-3m

Drs. Martinache & Smith, Oculists and Aurists, 313 Bush street, between Montgomery and Kearny. Hours for consultation, 12 to 3. 16v20-3m

F. Gruber, Naturalist, No. 626 California street, between Kearny and Dupont, San Francisco. Birds and animals stuffed to order. 13v20-3m

Block Tin and Solder Wire, broom wire, piano covering wire, etc., manufactured by Joshua Gray, 437 Brannan street. 24v19-3m

New Mining Notices.

Cayuga Chief Mining Company.—Location of Works: White Pine Mining District, County of White Pine, Nevada.

Notice is hereby given, that at a meeting of the Board of Trustees of said Company, held on the twenty-ninth day of April, 1870, an assessment of fifteen cents per share was levied upon the capital stock of said Company, payable immediately, in United States gold coin, to the Secretary, at the office of the Company, Room 5, No. 302 Montgomery street, San Francisco, California.

Any stock upon which said assessment shall remain unpaid on the thirty-first day of May, 1870, shall be deemed delinquent, and will be duly advertised for sale at public auction, and unless payment shall be made before, will be sold on Tuesday, the twenty-first day of June, 1870, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Trustees.

WM. H. WATSON, Secretary.

Office, Room No. 5 No. 302 Montgomery street, San Francisco, Cal. my7

Land Purchasers' Association.—Notice.

At a meeting of the Board of Trustees of the Land Purchasers' Association, held May 3d, 1870, the following resolution was adopted by unanimous vote:

Resolved, That an assessment of ten dollars per share, gold coin, be, and the same is hereby levied, upon each and every share of the capital stock of the Land Purchasers' Association now held by subscribers thereto; being for the monthly installment falling due and payable May 1st, 1870. Said assessment is payable on or before the thirtieth day of May, A. D. 1870, to James F. Crosett, Secretary, at the office of the Association, No. 304 Montgomery street, San Francisco.

Any stock upon which said assessment shall remain unpaid on the thirtieth day of May, A. D. 1870, shall be deemed delinquent, and will be advertised for sale at public auction, and unless payment shall be made before, will be sold at the office of the Secretary, on the twenty-eighth day of June, A. D. 1870, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

J. F. CROSETT, Secretary.

Office, 304 Montgomery street, San Francisco. m7-4w

Nevada Land and Mining Company.—Location of Works: Steptoe, Johnson & Latham, Antelope and Clifton Districts, Elko County, State of Nevada.

Notice is hereby given, that at a meeting of the Board of Trustees of said Company, held on the third day of May, 1870, an assessment of three (3) cents per share was levied upon the capital stock of said Company, payable immediately, in United States gold coin, to the Secretary, at his office, Room 5, No. 302 Montgomery street, San Francisco, California.

Any stock upon which said assessment shall remain unpaid on Tuesday, the seventh day of June, 1870, shall be deemed delinquent, and will be duly advertised for sale at public auction, and unless payment shall be made before, will be sold on Tuesday, the twenty-eighth day of June, 1870, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Trustees.

WM. H. WATSON, Secretary.

Office, Room 5, No. 302 Montgomery street, San Francisco, California. my7

Pinto Mining Company.—Location of Works: "Silverado," Pinto District, White Pine County, Nevada.

Notice is hereby given, that at a meeting of the Board of Trustees of said Company, held on the second day of May, 1870, an assessment of ten cents per share was levied upon the capital stock of said Company, payable immediately, in United States gold and silver coin, to the Secretary, No. 426 Montgomery street, San Francisco, California.

Any stock upon which said assessment shall remain unpaid on the second (2d) day of June, 1870, shall be deemed delinquent, and will be duly advertised for sale at public auction, and unless payment shall be made before, will be sold on Monday, the twentieth (20th) day of June, 1870, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Trustees.

D. B. ARROWSMITH, Secretary.

Office, 425 Montgomery street. 1: v20

Silver Vault Tunnel and Mining Company.

Location of Works: White Pine Mining District, White Pine County, State of Nevada.

Notice is hereby given, that at a meeting of the Board of Trustees of said Company, held on the third (3d) day of May, A. D. 1870, an assessment of five (5) cents per share was levied upon the capital stock of said Company, payable immediately, in United States gold coin, to the Secretary, at the office of the Company, Room 23 Hayward's Building, No. 419 California street, San Francisco, California.

Any stock upon which said assessment shall remain unpaid on Thursday, the ninth day of June, A. D. 1870, shall be deemed delinquent, and will be duly advertised for sale at public auction, and unless payment shall be made before, will be sold on Wednesday, the twenty-ninth day of June, 1870, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Trustees.

JOSEPH L. KING, Secretary.

Office, Room No. 23 Hayward's Building, No. 419 California street, San Francisco, California. my7

Mining Notices--Continued.

Alban Gold and Silver Mining Company.—

Location of Works: Virginia, Storey County, State of Nevada.

Notice.—There are delinquent upon the following described stock, on account of assessment levied on the twenty-first day of March, 1870, the several amounts set opposite the names of the respective shareholders as follows:

Names.	No. Certificate.	No. Shares.	Amount.
J Ball	79	5	25

RHEUMATISM, GOUT AND NEURALGIA

CURES GUARANTEED.

Has cured Thousands. Has never been known
One bottle will relieve you.

OFFICE, No. 121 POST STREET.

Agents Wanted in every City and Town.—Terms Liberal.

Dr. S. Girard Smith, 621 *Kearny street*,—Dear Sir It would be hard for me to say how much I thank you for the benefit your ARAMIRACULAS has conferred on me in curing my RHEUMATISM. I was confined to my bed when I first commenced to take your medicine, and after using ONE BOTTLE I am now able to work as well as before. If you know anything about having that afflictive complaint, you must know how good it is to be cured. I will state to those who may not believe in your medicine, that they can be convinced by referring them to me. Very respectfully, yours,

ENON HARRIS,
Everard's Auction Rooms, 527 Kearny street.

Statement of an old and well-known Physician who has practiced extensively in Europe and America.

We must admit that the many systems of medicine by which we have attempted to heal the human body, and rid it of disease, from the science of ALLOPATHY down to HYDROPATHY, how little they have succeeded, time has abundantly shown by their number of failures. In the cure of RHEUMATISM, GOUT and NEURALGIA, Dr. S. Girard Smith has laid aside the old way and adopted a system, so simple, that I must admit, is so natural and direct, that it recommends itself to all who are suffering with the above diseases. And it challenges and defies all the old methods of treatment. Although I have been educated through a regular course, and graduated in Europe, I must acknowledge the right, and also give due credit for personal benefit received by the new system as practiced by DR. S. GIRARD SMITH, which induces me to bear this testimony to its merits, for the benefit of suffering humanity.

A. M. HOFFMAN, M. D.,
11v20-3m New Orleans.

Ayer's
Hair Vigor,

For restoring Gray Hair to its natural Vitality and Color.

A dressing which is at once agreeable, healthy, and effectual for preserving the hair. *Faded or gray hair is soon restored to its original color with the gloss and freshness of youth.* Thin hair is thickened, falling hair checked, and baldness often, though not always, cured by its use. Nothing can restore the hair where the follicles are destroyed, or the glands atrophied and decayed. But such as remain can be saved for usefulness by this application. Instead of fouling the hair with a pasty sediment, it will keep it clean and vigorous. Its occasional use will prevent the hair from turning gray or falling off, and consequently prevent baldness. Free from those deleterious substances which make some preparations dangerous and injurious to the hair, the Vigor can only benefit but not harm it. If wanted merely for a

HAIR DRESSING,

nothing else can be found so desirable. Containing neither oil nor dye, it does not soil white cambric, and yet lasts long on the hair, giving it a rich glossy lustre and a grateful perfume.

Prepared by Dr. J. C. Ayer & Co.,
Practical and Analytical Chemists,
LOWELL, MASS.

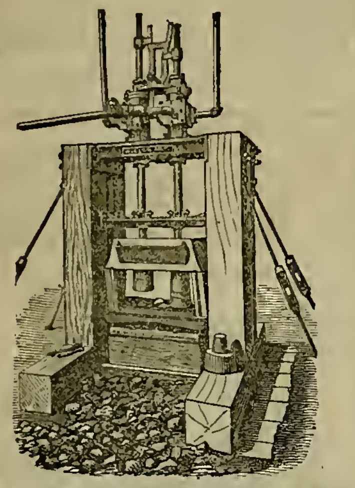
Machinery.

THE WILSON

Patent Steam Stamp Mill.



This extraordinary Mill, now so justly popular in the East, is now offered to the miners of the Pacific Coast. Having been in operation now for about eighteen months, the Company feel confident that the

WILSON STEAM STAMP MILL,

For Durability, Efficiency,

AND ECONOMY OF WORKING,

HAS NO EQUAL.

The Wilson Steam Stamp Mill is the only Steam Mill that has had the severe ordeal of practical working, and proved itself eminently successful. It is now in operation in several of the Eastern States and Territories, and gaining an envious popularity. The whole machine is so simple as to be readily understood by the most ordinary minds. In fact, its simplicity is its durability. The expense of crushing rock or cement with this Mill is less than one-half the expense of any other Stamp Mill, and less than one-half the cost. For further particulars inquire of

A. BICKNELL, Agent,
Nevada City, California,

Or of THE WILSON STEAM STAMP MILL CO., 326 Walnut street, Philadelphia, Pa.

Notice.—All persons are hereby warned not to manufacture or use any Steam Stamp Mills that are an infringement on the Wilson Patents, as they will be prosecuted to the utmost rigor of the law.

F. R. WILSON,
20v19-tf Supt. W. P. S. S. M. Co., Philadelphia.

VARNEY'S PATENT AMALGAMATOR.

These Machines Stand Unrivaled.

For rapidly pulverizing and amalgamating ores, they have no equal. No effort has been, or will be, spared to have them constructed in the most perfect manner, and of the great number now in operation, not one has ever required repairs. The constant and increasing demand for them is sufficient evidence of their merits.

They are constructed so as to apply steam directly into the pulp, or with steam bottoms, as desired.

This Amalgamator Operates as Follows:

The pan being filled, the motion of the muller forces the pulp to the center, where it is drawn down through the aperture and between the grinding surfaces. Thence it is thrown to the periphery into the quicksilver. The curved plates again draw it to the center, where it passes down, and to the circumference as before. Thus it is constantly passing in a regular flow between the grinding surfaces and into the quicksilver, until the ore is reduced to an impalpable powder, and the metal amalgamated.

Setlers made on the same principle excel all others.—They bring the pulp so constantly and perfectly in contact with quicksilver, that the particles are rapidly and completely absorbed.

Mill men are invited to examine these pans and setlers for themselves, at the office, 229 Fremont street,
1v1 San Francisco.

TO MILLMEN.

FOR SALE CHEAP.—A 10-stamp mill complete; engine about 35 horse-power; cylinder 12-inch bore and 30 inch stroke; boiler 16 feet long and 48 inch diameter; weight of stamps complete, 650 pounds. The whole is as good as new; has only been running four months. Will sell either engine or battery separate, and deliver it on the railroad at Auburn if required. For particulars apply to W. NAGEL, 702 Bush street, San Francisco, or to MOUNTAIN CO., Forest Hill, Placer county. 16v20-3m

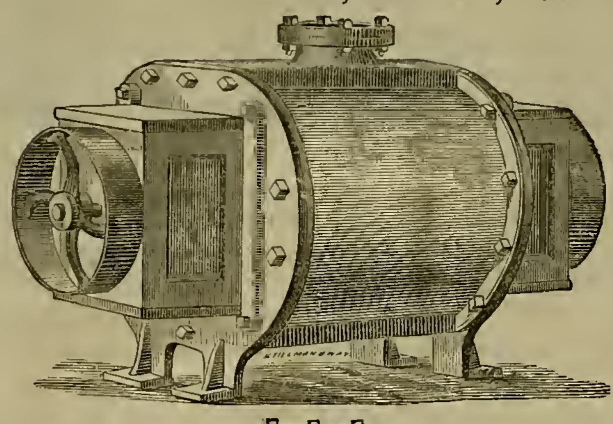
ROOT'S PATENT FORCE BLAST ROTARY BLOWER.

MANUFACTURED BY KEEP & BARGION,

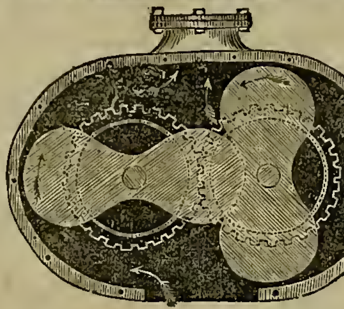
At the Globe Iron Works, Stockton, California.

Awarded the First Premium at the Paris Exposition.



Patented Nov. 1st, 1864; July 24 1866; and Oct. 9, 1866.

ADAPTED FOR **Smelting, Foundry, Mining and Steamships.**



REQUIRES **Fifty Per Cent.** LESS POWER **Than any Blower** Now in use.

One of these Blowers may be seen on exhibition at W. T. Garratt's Brass Foundry, corner of Mission and Fremont streets. They are also in use at the Almaden Quicksilver Mine; Gridley's Foundry, Gold Hill, Nevada; Ætna Iron Works, San Francisco, and many other places.

Caution.—Purchasers will find it to their advantage to apply direct to the Stockton Agency, as certain parties, not authorized to manufacture the Blower, have put in the market machines of inferior construction, which do not answer all the requirements of the genuine article.

Quartz, Saw and Grist Mill Irons, Steam Engines, Horse Powers, High and Low Pressure Steam Engines, Steamboats and Propellers, made at short notice.

For circulars and further information, address

The Loud-Cole Patent Case.

The Loud-Cole patent case has at last come to a definite conclusion. It has been appealed as often as it was possible, and the last time it was to the final tribunal, the District Court, where it was decided unequivocally in favor of Mr. Loud, to whom is awarded priority of invention, a decision which concides with all but one made previously. We have just received Judge Fisher's decision, which reviews the points made by the Commissioner of Patents in substance as follows:

The wheel made by Loud in September 1868 was certainly in as practical a form as that made by Cole in December. Neither of them seems to have been tried as yet upon a steamer of any size, but if the model made by Cole in December is a practical form of the invention, that made by Loud is no less so. As to the second ground of rejecting Loud, it is only necessary to observe that his experiment in September was *not* a purposeless one. The X wheel was made by him for the purpose of obtaining a propelling side wheel which should operate by the fish-tail or scull motion, instead of a paddle wheel, and not with the object of adapting the scull wheel to a narrow wheel-house, as the Commissioner seems to regard it. So far from abandoning his X wheel, Lond had it in his trunk on his way back to California. The fact that Loud did not remember that his X wheel would require no wider wheel house than the V wheel is no point against him. We cannot think Loud so unintelligent as to discuss which of the forms was the better and yet be ignorant whether he had conceived anything at all. Priority is awarded to A. C. Loud.

Sheffield Scientific School

Of Yale College, New Haven, Conn.

This department of Yale College, instituted in 1840, and endowed with the National Land Grant in 1866, furnishes advanced instruction in the various branches of Mathematical, Physical, and Natural Science.

The School is under the direction of the President of the College, a Board of thirteen Professors in differe specialties, and six assistant instructors.

Regular courses of study, leading to the degree of Bachelor of Philosophy, conferred by Yale College, are arranged as follows: 1—CHEMISTRY AND MINERALOGY. 2—CIVIL ENGINEERING. 3—MECHANICAL ENGINEERING. 4—MINING ENGINEERING AND METALLURGY. 5—AGRICULTURE. 6—NATURAL HISTORY AND GEOLOGY. and 7—SELECT COURSE.

Advanced students are also admitted to optional courses, and if already College graduates, are received as candidates for the degree of Doctor of Philosophy.

Tuition, $125 per year of forty weeks.

The Libraries, Museums, Laboratories and Apparatus accessible to students, are varied and extensive.

For copies of the Annual Circular and Report, letters may be addressed to the "Secretary of the Sheffield Scientific School," New Haven, Conn. v16-1y16p

WIESTER & CO.,

PATENT BROKERS,

No. 314 Bush Street, San Francisco.

PATENTS BOUGHT AND SOLD ON COMMISSION.

For the benefit of those who live at a distance from the city, we give below a brief description of a few of the valuable Patents which we have in our office. It may be well to state here that no Patent is received by us for negotiation until it is first endorsed by reliable experts, to whom each is subjected for acceptance or rejection. Wo treat all patents alike, recommending only where true merit is found in the invention.

Odermatt & Ettlin's Fountain Pen.

PAT'D. AP. 6. 1869.

We call the attention of manufacturers to this new invention for supplying writing and drawing pens with a constant flow of ink. The pen-stalk contains sufficient ink to last for two or three days' constant use, and is provided with stop-cocks, which make it perfectly safe for carrying in the pocket. The flow of ink is under perfect control of the operator. A slight pressure on the thumb and fore-finger on the elastic sides of the holder is all that is required to regulate the flow of ink to suit the writer. It never blots unless forced to do so. The cost to manufacture is small, and the demand for a good Fountain Pen is very extensive among all classes of literary and business men. A sample of this invention can be seen and tried at our office, 314 Bush street, San Francisco. The entire Patent, or the Right for any State, can be bought on reasonable terms. Full particulars furnished on application.

NEW LIGHT ON A NEW PRINCIPLE'

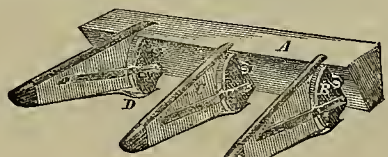
Gas for everybody in the city and in the country. Equal to coal gas at one-half the cost. The gas is generated and burned in a new style Vapor Lamp. No wick, no chimney, no explosion; and no man who is out of business and has a few dollars should fail to purchase a County or State Right and commence making money. Parties owning territory get the Lamps at Manufacturers' prices. Call and examine the light, or write for particulars.

A NEW PAPER FILE AND MUSIC FOLIO.

Two excellent inventions included in one patent. Either can be manufactured at a small cost, and neither has an equal in its line. No more expense for binding music. Each sheet has a complete and durable binding as soon as it is placed in the folio. The California Legislature has endorsed tho Paper File by purchasing three hundred and fifty, to take the place of the old style binders. It certainly is the most complete article of the kind ever invented. Whoever buys the right to manufacture and sell this invention will secure a good basis for a profitable business. Only the Territory west of the Rocky Mountains for sale. Parties in tho city should call and examine the article. Full particulars furnished on application.

WIESTER & CO.,
314 Bush Street, San Francisco.

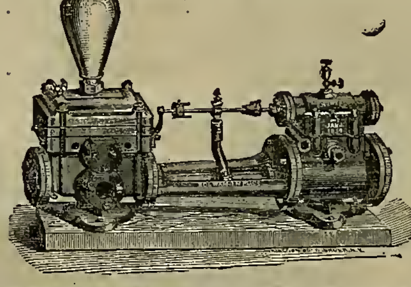
BONNEY'S IMPROVED GRAIN LIFTER.



The advertisement of this important improvement will appear next week. For particulars apply to

WIESTER & CO.,
314 Bush street, San Francisco.

KNOWLES' PATENT STEAM PUMP.



This Pump has received the HIGHEST PREMIUM at every Fair where it has been exhibited. It is of superior make and finish; has all ground joints; no packing required. It is positive in its action. It is impossible to stop it on centers. It will always start without using a starting bar. We have two hundred different styles and sizes adapted for Factories, Steamships, Sugar Refineries, Breweries, Distilleries, Gas Works, Oil Works, Soap Works, Paper Mills, Tanneries, Bleacheries, Laundries, Railroad Purposes, Quarries, Petroleum Mines, Drainage, etc. Large Pumps for Water Works. Fire and Wrecking Pumps. ☞Pumps guaranteed for every situation.

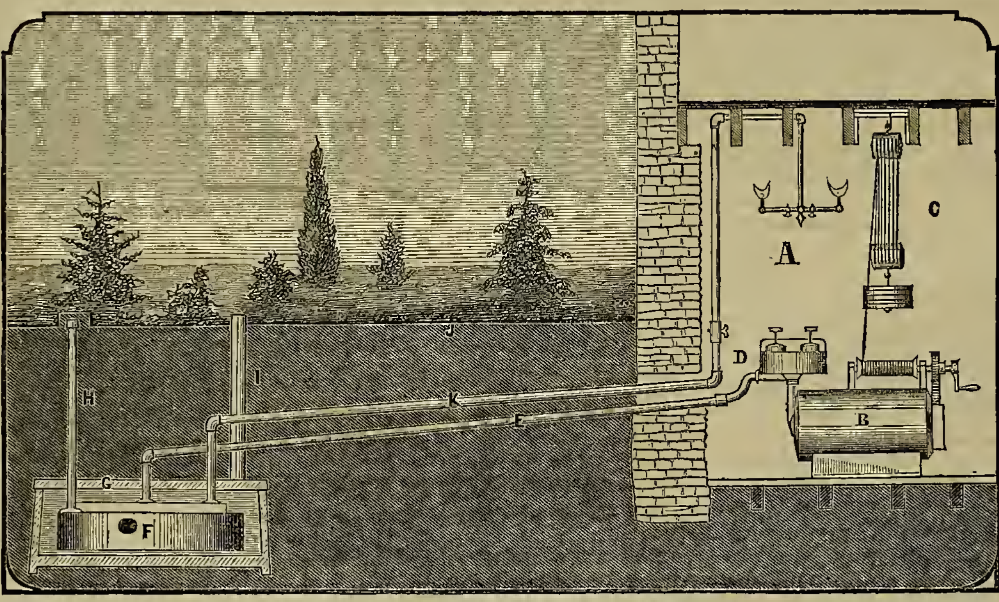
Gas Works for Country Residences.

The American shows traits of his national character in the matter of lighting his house as well in other ways. Go where we may in other parts of the world we find no such extensive use of gas, enabling the householder to have a brilliant light in each room with the least amount of trouble to himself. The more conservative character of European nations lead them to retain the older methods of illumination to a great extent, but in the United States no city resident will willingly be without his gas-light, and the inhabitant of the country desires as well some similar contrivance.

When the chemists showed that petroleum was composed of a variety of hydro-carbons which, in a high degree, offer in a concentrated and convenient form the elements necessary to the production of illuminating gases, and that these gases are purer than any coal gas, numberless designs were devised for utilizing these products for illumination in common life. If we distil our crude petroleum into a condenser, we can easily get a number of different products which volatilize at different degrees of heat, and which we can, therefore, obtain separately. One of the first products distilled over goes under the common name of gasolene, and this, on account of its easy evaporation, is used for the production of illuminating gas, among other purposes.



PNEUMATIC GAS MACHINE FOR COUNTRY RESIDENCES.

Of the apparatus hitherto invented, none seems to have proved altogether successful. We give, however, this week, an illustration of a machine which, it is claimed, obviates all difficulties, and produces a cheap and excellent light. While not prepared to pronounce this a complete success, still we have been shown such certificates in its favor by those who have used it, that we present it to our readers for their consideration.

The illustration shows one of the pneumatic gas machines with its attachments. A represents the interior of the basement of a house. Here is placed an air-pump, B, which forces the air through the pipe, E, into the machine and over the surface of the gasolene, whereby it becomes saturated with the inflammable hydro-carbons, and is returned through the pipe, K, to the house, where it is used like common gas. The air-pump, B, is driven by means of weights and pulleys, as shown at C, and a governor, D, regulates the amount of air forced into the gasolene tank.

The gas works consist of a tank or a "carbureter," F, made of galvanized iron and divided up into compartments, connecting with one another, so that the air is forced to pass over a large surface of the gasolene, which is put into this machine. The carbureter is inclosed in a tank, G, which is filled with water. The whole is placed some four feet below the surface of the ground, J, at any distance from the house. H is a pipe for replenishing the gasolene, and I, a similar pipe, for the water tank.

It is necessary to apply a certain amount of heat to evaporate the gasolene and thus charge the air, and the manner of doing this forms one of the principal points of the invention. The temperature of the earth is sufficient for this, and as this temperature is first communicated to the surrounding water, an even degree of heat is secured during the whole year, it is claimed. And then as the gasolene is outside of the house and under the ground, there is no danger of accident by fire, so that all insurance companies insure buildings where these works are used without extra charge. The apparatus is constructed wholly of galvanized iron and will last a long time with but little or no repair, while any one can, in a couple of minutes, put the works in condition to afford a supply of gas for the night. The gasolene requires to be put in but once a year.

The apparatus has been in successful operation for the past six months in the Pacific Iron Works in this city, and has been introduced into the State Deaf and Dumb Asylum at Berkley, and into various private residences throughout the State. The testimonials from the users are strong, and it would seem that persons in the country might now enjoy the luxury of gas and at a small expense.

The Pacific Pneumatic Gas Company, of this city, are owners of the patent, and are willing to put their machine into any house, and at the end of a month, if parties are not satisfied, to remove it without charge. Persons desiring further details, explanations or testimonials, can obtain the same by applying to the Company, by letter or otherwise, at their office, No. 206 Sansome street, San Francisco.

General Mining Revival.

Reports from various parts of the globe seem to indicate that mining is receiving a fresh stimulus this year and getting a firmer and more stable basis. In England there is certainly much greater confidence now than there has been previously, and there is plenty of English capital ready for investment. The mines in Wales are yielding very large profits; witness the celebrated Van mine, which was sold a year ago for $150,000, but which has since made enormous returns, and is now valued at ten times its late price. In Italy the business is gradually recovering from its long continued depression, and as liberal concessions are made by the Government, capital is being invested there in quite large amounts. In Australia, according to all accounts, prospects are better than ever, and the only fear which we have seen expressed was, that there might perhaps be a scarcity of laborers. In France there is increased activity, in coal and iron especially, and Belgium and Prussia are yielding large returns.

Reports which come to us through various sources from the distant mines of Russia, denote that in these regions, too, there is an improvement. The Russian Government has long intended to sell its mines and smelting-works, which have in many cases been unprofitable simply on account of official peculations, and is now really on the point of so doing, it is said. A couple of years ago, when in that country and also when in England, we heard of several companies who were ready to invest in these works, but were waiting for favorable terms; and it is to be hoped that soon good management will succeed the corrupt official charge which has so long burdened the mineral resources of the Empire. From other lands, also, we hear favorable indications.

In our Western States and Territories mining is receiving a renewed impulse, and we may expect a quite general revival this year. Not only are new discoveries being made, but old ones are being taken up and re-worked. From Arizona and New Mexico come very flattering accounts, some evidently greatly exaggerated, but still enough is stated to prove that there is a strong foundation of truth. English capital is commencing to flow into Colorado and the Territory will this year produce a largely increased yield. The Mormons have concluded to no longer oppose the development of the mineral resources of Utah. Nevada reports many excellent discoveries in various parts of the State, and mining operations are meeting with signal success. From Montana we hear of the brightest prospects, and the cry there is ever for more laborers. Its papers are continually calling for more men. All over the country, they say, the scarcity of working-men is felt to be the only drawback for the production of more gold than ever before, as well as for the successful working of farms. Idaho utters a similar cry.

In California we see much better prospects. The San Diego excitement, although it has died away to a great extent, has called attention to that part of the State, and will result in the developmen of valuable property. There are other instances too numerous to mention. Thus in Nevada county many hydraulic claims have been located, and in Placer county, at Ophir, mines which have been dead for years are now being worked extensively and profitably.

Better than all is the prospect that there will be more *legitimate* mining than ever before. The wild speculations and open mismanagement of former days, which have proved so fatal to the interest, are, we may hope, on the decrease. We see a growing disposition to regard mining investments as permanent. Economy is being recognized as an essential feature, and the necessity of having better educated superintendents is gradually dawning on the public mind. Taking everything into consideration, we feel justified in expecting everywhere a much brighter future.

Mining in Humboldt County, Nevada.

[Written for the Scientific Press.]

Editors Press:—Galena is situated some eight miles from Battle Mountain, and although laid out but a short time ago, by Robert McBeth, has now a population of over 250, and is growing steadily. It takes its name from the ore found in and around it. The veins as far as known have a north and south strike with a westerly dip. Numerous locations have been made, but only comparatively little work has been done really towards developing the ledges.

The Butte Mine.

The Butte mine, situated one mile below the town, was located by G. W. Fox and R. McBeth—the discoverers of Battle Mountain district—in the summer of 1867. They have 22 miners at work, running tunnels and stoping, under the supervision of J. T. Maclean, who owns an interest in the mine. I am told that men now working for wages here refused at one time to take one half the claim (500 feet) in payment for district assessments on the whole, amounting to a few days work only; and now they are said to be getting out about 40 tons per month, which yield from $200 to $300 per ton in the mill. The shaft is down 75 feet. The vein is from two to four feet wide and dips at an angle of about 45 degrees. The ore averages $150 per ton, and they have a large quantity of first and second-class ore for shipment. Ten tons have lately been sent to San Francisco for reduction. The mine is situated on a high ridge and worked by shafts and tunnels, and is considered by practical miners to be the best in the district. The company paid a dividend in March which amounted to $2,500, and the mine has paid all expenses since it was discovered.

The Shiloh and White Mines.

The Shiloh mine is located to the north of the town and has been leased to Mr. H. L. Spargur for a short time. Mr. S. has sunk a shaft fifty feet and is running drifts from the bottom of this. The lead is four feet wide and has yielded large amounts of good first-class ore. This, shipped to San Francisco, yielded $100 per ton in silver and 50 to 80 per cent. of lead.

North of the Shiloh is the White mine, which is supposed to be an extension, and at a depth of 40 feet produces similar ore. This is also leased to a company which is now engaged in extracting and shipping ore. A lot of 29 tons, recently sent to San Francisco, contained from $150 to $200 per ton in silver and a high percentage of lead. The second-class ore is piled up on the dump, and will doubtless be the first worked by Bruce & Co. when they get their smelting works in operation.

Avalanche and other Mines.

Passing over to Copper Cañon, we see to the left of the road the Avalanche mine, located near a creek. There is a shaft six feet square, which has been sunk twenty-six feet on the ledge, but the water drove out the workmen and operations are suspended for the present.

The New Jersey and Cheekee(?) mine is owned by Fenton and Smith. The ledge is twenty-two inches wide and the shaft is eighty feet deep. There is water in the shaft, but a tunnel is to be run in a few weeks. Two tons of ore sent to San Francisco a short time ago brought the owners $316.

The Buena Vista mine is the oldest location in the district. The ledge crops out on the mountain side a distance of several hundred feet, and this ore assays from $40 to $400 per ton in silver. A tunnel has been run in 150 feet in the hill-side, and a shaft now being sunk on the foot-wall, from the tunnel level, has disclosed a fine body of ore averaging about $100 to the ton. A large amount of money has been expended on this mine.

Bruce & Co's Smelting Works.

Two miles from the town, near the road leading to the Butte mine, are the smelting works of Martin Bruce & Co. They are building a blast furnace, 24 by 30 inches, interior dimensions, and 12 feet up to the feeding hole. The building stone comes from the Hot Springs on the C. P. R. R., where, it is said, the hot water, bubbling up, flows over the sand and dirt and forms a hard stone. It is expected that the furnace will be at work by the middle of May, running through ten tons daily. Charcoal will be used as fuel.

The Copper Mines

Of Copper Cañon are creating considerable excitement, and the Battle Mountain Copper Mining Co., of Liverpool, appears to be doing exceedingly well. This company purchased the mine eight months ago, but have been at work only about six months, and are now shipping to England some 80 to 100 tons monthly. They are about to take out an U. S. Patent. For the transaction of the general financial business here, the company sent out their secretary, Mr. A. Bond, a very pleasant and agreeable gentleman, and they have, as General Superintendent of the mine, Capt. Wm. Nancarrow. They are running two shafts, 60 to 70 feet deep, and three large tunnels, one being already 180 feet long, and employ 22 men. The ledge or deposit is from eight to ten feet wide and abounds in rich ore, holding much red oxide of copper. This mine is certainly one of the best, if not the best, I have ever seen! I understand that the company intends erecting large reduction works near this district at an early day, and I doubt not but that this would be a good move, and pay largely.

Remarks.

There are other mines here worthy of mention but which I have not had time to visit. I have great confidence, however, from what I have seen and heard, of the future of these two districts (Battle Mountain and Galena). The smelting works will no doubt aid greatly in developing the base metal ores, by enabling miners to get returns from mines which otherwise would not yield them so speedy profits. There are, moreover, without doubt, many good veins still awaiting the enterprising prospector. I am well pleased with both the country and the people, and all the more as the people here seem determined to conduct mining as a legitimate business and not to consider it as a basis for Montgomery street speculation: W. H. M.

Battle Mountain Station, April 27, 1870.

Sketches of El Dorado County.

[Written for the Scientific Press.]

Hydraulic Mining.

Editors Press:—Spanish Hill is one of the offshoots or spurs of Hangtown Hill, pushing towards the north, until intersected by Hangtown creek, and within the city limits. William Blacklock & Co., about two years ago, purchased a claim near the middle of this hill, which had been worked more or less since 1852. The cut through the rim rock was not of sufficient depth for practical working, and this company excavated a cut through the solid rock from five to forty-five feet in depth and 500 feet in length, for sluicing the gravel and catching the gold. The pay streak of gravel is from one to fifteen feet in depth, covering an area 400x2,000 feet, or more than eighteen acres. Almost a mountain of dirt has to be removed to get to pay gravel, which prospects from one to fifty cents per pan. Already some five acres of surface have been removed, and some two acres of gravel uncovered and washed at a depth of from 100 to 125 feet. They are unable to procure water for more than four hours out of twenty-four, using some 200 inches, having an 11-inch pipe 1,150 feet long and 250 feet pressure. The Craig nozzle is in use here, saving, as Mr. Blacklock informed me, the labor of two men, without the danger attending the old canvas connecting hose. The water is driven against the bank through a 4-inch nozzle, and breaks down the dirt and gravel at a fearful rate, rolling large boulders into the cut, then to the sluices and down into ravine below. Sixty tons per hour are easily removed and dumped at the end of the sluices. Considerable gold adheres to the clay and is carried off and lost until it has been exposed to the weather for a time and slacked, when it will be washed again. The sluices are about thirty inches wide by eighteen inches deep, with 5-inch blocks nearly covering the bottoms and 3-inch scantling fastened to the sides. The wear from the gravel and boulders requires both bottom and sides to be frequently replaced by new ones. Quicksilver is placed along the bottom between the blocks, and most of the gold is there caught. The fall of the sluices is about two inches in twelve feet. This company have applied what is called an undercurrent sluice—*i. e.*, fine riffles or screens are placed over an opening cut in the bottom of the main sluice, and the fine gold, black sand and dirt with some water drop through into a sluice prepared for that purpose, in which there is a large quantity of quicksilver, which amalgamates with the gold, and the water is again returned to the main sluice below. The informed me that their claim yielded over $10 per hour, or more than $100 per day (of ten hours) while using water. When using water, five men are employed.

C. W. Brewster, banker, who purchased most of the dust, informs me that more than $250,000 have been taken from the Blacklock, Golden Gate and Hook and Ladder companies since 1854. Those three claims cover the middle and north end of this spur. South and near the main ridge is the Macumber Bros. & Co's claim, in size about half that of Blacklock & Co. Otherwise, what is said of Blacklock & Co. will apply to this claim. At the head of Spanish Ravine, and adjoining Macumber's, is Maynard & Bro's claim, from which large amounts of gold were taken in 1852,'3 and '4. It is worked by tunnel. If water could be had it would be an excellent hydraulic claim. The Buckeye claim, situated on the south side of Hangtown Hill, is owned by G. W. Swan, now of your city. This claim has been worked more or less for four years, more to keep possession until water can be obtained, than for profit. I have seen several nuggets taken from this claim varying in size from two to five ounces. Two weeks ago a man was set at work on this claim, and in a short time took out a chunk two inches long by one-half inch broad, weighing over three ounces. Swan says he intends to keep this claim as long as he lives, or until he can get water to work it.

Claims on Weber Creek.

Sailor Jack's claim, owned by Donaldson & Co., is situated between the South and Middle fork of Weber creek, some six miles east of Placerville. This claim is worked by a tunnel under a cement or lava, which covers the hill. There is a fine bed of gravel which extends up the ridge for several miles. The gravel wheeled out last summer, and washed in December, yielded, I am told, over $10,000. Water for washing can only be had after the rains commence. Nearly opposite and south of the South fork of Weber creek, some two miles below Newtown, are a number of excellent claims, a few only of which I visited. T. O'Brien's, gravel from four to forty feet, eleven-inch iron pipe with 140 feet pressure, pays from $6,000 to $10,000 per annum. J. Dentz & Co. have spent $2,000 and have just opened a fine prospect similar to O'Brien's. C. P Steadman, hydraulic 11-inch pipe, just opened; gravel from 40 to 100 feet, the principal pay being near the bottom. Andrews & Co. have been at work three years and have ground to work for ten; the claim pays well. Last winter's run after "robbing" sluices weekly to pay expenses, cleaned up over twenty pounds in the Spring. Water is more plentiful on this side of Weber creek, being taken from the Euerka ditch, which takes its water from the Cosumnes river.

Hydraulic mining is prosecuted much the same everywhere. What is said of Blacklock & Co., will, with slight variation, apply to all. I am told by a practical mineralogist that if the under-current process was resorted to, to save black sand, which contains a large amount of fine gold, and mills prepared for working it, that both mill-owners and miners could make large sums of money. It is evident that large amounts of gold pass out of the sluices while being washed. Hangtown creek within this city has been worked 12 times in 20 years, and every time the gold which is collected with quicksilver has shown to be finer than that of the previous washings, until now it is as fine as flour. Black sand, with some fine gold, can be obtained in large quantites from the creek. The late discoveries of gold-bearing quartz have created a want among miners for a custom mill, conveniently situated, for delivering quartz, and would pay capitalists well on an investment of $3,000 or $4,000 being sure of steady employment.

E. N. S.

Placerville, April 25th, 1870.

Law for the Preservation of Fish.

An Act to provide for the restoration and preservation of fish in the waters of this State.

The people of the State of California, represented in Senate and Assembly, do enact as follows:

Section 1. The Governor of this State is hereby authorized and empowered to appoint three persons, to be styled Fish Commissioners, whose duty it shall be to establish fish breederies upon such of the waters of this State as in their judgment shall be most available for the purpose of stocking and supplying the streams, lakes and bays of the State, with both foreign and native fish, and for such purposes may purchase and import from other States and countries the spawn or ova of valuable fish suitable for food, and may introduce the same when obtained into such rivers, streams, lakes or bays as they may deem suited to the habits and successful culture of such fish. They may also employ persons who are skillful and expert in the business of fish breeding, and may superintend and direct the construction of fish ways and fish ladders, that may be built in the streams and waters of this State. The Commissioners may in their discretion distribute the ova or spawn to be procured by them to such persons as have proper lakes, ponds or streams for the propagation and breeding of fish, and who will, without expense to the State, take charge of such breeding and propagation.

Section 2. Such Commissioners shall hold their office for the term of four years, unless others shall be appointed to fill the vacancies occasioned by the death, resignation or inability to attend to the duties required.

Section 3. It shall be the duty of the Commissioners to require as far as practicable all persons, firms and corporations who have erected mill dams, water weirs or other obstructions on rivers or streams, within the waters of this State, within six months after the passage of this Act to construct and keep in repair, fish ways or fish ladders at such mill dams, water weirs or obstructions, so that at all seasons of the year fish may ascend above such dam, weir or obstruction to deposit their spawn. Any person, firm or corporation owning such mill, dam or obstruction, who shall fail or refuse to construct or keep in repair such fish way or fish ladder after having been notified and required by the Commissioners to do so, shall be deemed guilty of misdemeanor, and, upon conviction thereof, shall be punished by a fine not exceeding five hundred dollars, for every such neglect or refusal. The fines and penalties that may be received for convictions under this section shall be paid, one-half to the District Attorney, who shall prosecute the suit, and one-half to the common school fund of the county.

Section 4. It shall not be lawful for any person or persons between the first days of January and June of each year to catch or kill any river, lake, brook or salmon trout in any of the streams, rivers, lakes or other waters within this State, with any string gill-net, or any spear, wire fence, basket traps, explosive material or other implements or substance, or in any way or manner except by hook and line, and it shall not be lawful at any time for any person or persons to catch or kill such fish in any of the waters of this State by the use of traps, gill-nets or set-nets, or any poisonous, deleterious or stupefying drug, explosive material or other substance, provided, however, that nothing in this Act shall be construed to prohibit the taking of fish in private houses, constructed expressly for the raising of fish by the owners thereof, and provided further that any person wanting spawn for the propagation of fish, may take fish from their spawning beds or elsewhere during the spawn season. Any person violating the provisions of this section shall be deemed guilty of misdemeanor, and, upon conviction thereof, shall be punished by a fine of not less than twenty-five dollars, nor more than five hundred dollars, one-half to be paid to the District Attorney who shall prosecute the suit, and one-half to be paid into the common school fund of the county.

Section 5. Every person who shall in any manner take or carry away any trout or other fish from any stream, pond or reservoir belonging to any person, or corporation, which stream, pond or reservoir has been stocked with fish for hatching the egg or spawn, or by placing therein, without the consent of the owner of the land, covered by, and adjoining such stream, pond or reservoir, or without the consent of the agent of the corporation, if such land belong to a corporation, shall be punished by a fine of not less than two, nor more than ten dollars for every fish so taken or carried away, and shall also be liable to the owner of such stream, pond or reservoir in a civil suit for the full value of all fish so taken or carried away.

Section 6. All persons engaged in the business of fishing in the bays or harbors of this State, with seines or traps, and who shall by said seines or traps, or any other means whatever, capture the young of any species of fish valuable for food, but which at the time of capture are unfit for use as food, shall return the same to the water; every person who shall violate the provisions of this section shall be deemed guilty of a misdemeanor, and, on conviction thereof, shall be punished by a fine of not less than one hundred dollars, nor more than five hundred dollars, or imprisonment in the County Jail not exceeding six months, or by both such fine and imprisonment in the discretion of the Court. One-third of all the penalties received under this section shall be paid to the informer, one-third to the District Attorney of the county prosecuting the suit, and one-third to the school fund of the county.

Section 7. The Commissioners authorized to be appointed by this Act shall receive no compensation for their services. Their necessary expenses incidental to procuring and distributing the ova or spawn of fish in the employment of fish breeders, and in carrying out the provisions of this Act, shall be paid from the appropriations herein made, upon accounts or vouchers, to be approved by the State Board of Examiners. The Commissioners shall report biannually to the Governor an account of their transactions under this Act, and make an exhibit of their expenditure of money under its provisions.

Section 8. The sum of five thousand dollars is hereby appropriated out of any money in the General Fund not otherwise appropriated, and the Controller is hereby authorized to draw his warrant on the Treasury in payment of accounts of the Board of Fish Commissioners as herein authorized.

Section 9. Nothing in this Act shall be construed to prohibit or prevent Indians from taking trout in any of the streams or lakes of the State, at any time by the same means hereinbefore usually used and employed by them.

Section 10. An Act for the preservation of trout, approved April seventeenth, eighteen hundred and sixty-one, and the Act amendatory thereof and supplementary thereto, approved March twenty-seventh, eighteen hundred and sixty-two, and an Act to amend an Act entitled an Act amendatory of and supplementary to an Act for the preservation of trout, approved March twenty-seventh, eighteen hundred and sixty-two, approved March second, eighteen hundred and sixty-six, are hereby repealed.

Section 11. This Act shall take effect immediately.

Approved April 2d, 1870

* * *

Taro, the Japanese student, who recently died very suddenly, at Rutgers College, Brunswick, N. J., would have graduated with the highest honors of his class if he had lived four months longer.

Silk Manufactures.—In Patterson, N. J., there are sixteen silk factories, employing 3,500 hands and running not less than 70,000 spindles.

Mechanical Progress.

Device for Preventing Boiler Explosions.—*La Propagation Industrielle* illustrates an arrangement for this purpose, based upon the theory of Messrs. Dufour and Kaynen, that irregular ebullition is a fruitful cause of explosion in steam generators; this irregularity proceeding from excessive production of steam at one part of the boiler and little or none at another. Primarily, this results from the immobility of the water in the boiler; and the object of the apparatus is to secure its agitation. The water in the boiler is caused by the steam pressure to rise in a pipe, the lower portion of which is curved and reaches below the water level. A plunger is thus forced up, and by this means a valve connected with the steam pipe is opened. The steam thus admitted at the top forces down the water into the boiler again. This operation is repeated, and the circulation thus kept continuous.

Compounding Single Cylinder Beam Engines.—This practice, says *Engineering*, is every day gaining ground in our manufacturing districts. The manner in which the compounding is carried out, varies. In the majority of instances, the high-pressure cylinder is placed between the main center and the crank shaft; but in many instances, a horizontal high-pressure cylinder is placed by the side of the existing low pressure one, the piston of the high-pressure cylinder being coupled by a connecting rod to an independent crank on the crank shaft of the original engine. Mr. Ramsbottom, of Leeds, also has compounded a number of engines by substituting for the existing single cylinder a group of three cylinders, placed side by side; the two outer ones, which are of smaller diameter than the other, being the high-pressure, and the central one the low-pressure cylinder. In this arrangement, which is a very neat one, the three piston rods are attached to one crosshead, which is coupled to the parallel motion in the usual way.

"Cast Malleable" Iron.—This is a peculiar material made by McHaffie & Co., of Glasgow, for the cylinders of hydraulic presses. *Engineering* says of it: "The method of producing this material—which, by-the-bye, must not be confounded with ordinary malleable cast iron—is kept a secret by the manufacturers; and all that is known concerning it is, that there is charged into the cupolas with the metal a certain mixture inclosed in cast-iron pots, and that the castings after pouring are subjected to a slow annealing process. Whatever the mode of manufacturing may be, however, it is certain that the material has proved itself a very suitable one for the construction of hydraulic press cylinders, and Messrs. McHaffie have already constructed a number of such. They are prepared to make cylinders capable of withstanding a pressure of 6 tons per square inch, and of sizes up to 12 tons in weight."

Wooden Water Pipes.—In Ithaca, New York, they have a new method of manufacturing these. The lumber is, by peculiar hollow augers, of different sizes, cut or bored out in concentric tubes or pipes, only leaving at last a small core, a little less than the bore of the smallest pipe. In this way a piece of timber, originally ten inches in diameter, will *turn out* several pipes of, say 10, 8, 6, 4, and 3 inches in outer diameter, and about 1½ inches in thickness, or of greater thickness if required, by decreasing the sizes of the inner tubes proportionately. The hollow auger cuts away only from one-half to three-quarters of an inch. This piping is then properly strengthened by iron bands, and subjected to a bath of asphaltum or other cement to make it impervious to gas or water, and to prevent decay.

Punching of Metals.—General Morin recently read a paper before the French Academy detailing experiments which demonstrate that the same elements of resistance enter into the operation of punching as in that of shearing. In short, a punch and die may be considered as a shears with circular blades. The coefficient of pressure in punching, per any given area of section, will be exactly that for shearing the same area of section, without reference to the thickness of the material.

Dressing Millstones with "Bort."—The *Engineer* illustrates and describes the two machines for this purpose, which are respectively the representatives of the two classes which comprise all;—viz: the "rotatory" and "rectilinear." The first is that of Golay, a Frenchman, the other that of Young, a Scotchman. The latter and later is given for several reasons the preference. The following explanation of the term "bort" is copied from the journal named: "Popularly the term 'diamond,' or 'black diamond,' is applied to the stones used for dressing millstones; but the term is inaccurate, and bort—which is the substance really used—is not diamond. The diamond properly so called is a crystalline substance with an easy cleavage; and even when reduced to fine dust, the particles retain their crystalline structure; hence the grittiness, in which lies the great abrading power of the dust. Bort, on the contrary, is amorphous, or destitute of crystalline structure or cleavage, and its dust, having no grittiness or abrading power, is quite useless to lapidaries. Bort, probably like the diamond, consists mainly of carbon, but in an allotropic or different state. It is very remarkable that the amorphous bort should be harder than the crystalline diamond, but so it is, and a good specimen of bort will with a single steady rectilinear stroke cut in stone a groove one-eighth of an inch in depth—work which would be simple destruction to any translucent or crystalline diamond."

New Magnesian Cement.—The basis of the new artificial stone, of the Union Stone Company, Boston, which was described by Mr. Chauncey Smith, at a late meeting of the Society of Arts of the Massachusetts Institute of Technology, is a cement discovered by M. Sorel, of Paris. "It is simply calcined magnesia, dissolved in chloride of magnesia or other suitable solvents. The magnesite so abundant in several of the States furnishes ample material. M. Sorel, by mixing his cement with sand, makes tiles; mixed with flint, it forms whetstones and oil-stones; with kaolin, mouldings, ornaments and statues; with sawdust and similar materials, flooring, wainscoting and other elastic stone-like substances; with carbonate of lime, mantels and mosaics imitating and actually covered by marble. The cement is used in a liquid form, and the stone sets in a few hours; the magnesite must be calcined with great care, and the materials thoroughly mixed. The paste is run into molds, and compressed by repeated percussion, rather than by steady pressure."

Boiler Incrustations—Another Preventive.—The engine at the Darmstadt Gas works has worked day and night since 1854 almost without interruption, and the formation of calcareous deposits has been entirely prevented by the use of crude pyroligneous acid, combined with tar; it is either introduced into the boiler or mixed with the feed water. Since this mixture has been in use they have never had a stoppage through incrustation, and have never had to use a hammer to remove scale. Each year, during the summer, when less gas is required, the boiler is opened, and perhaps a couple of handfuls of loose sediment taken from the bottom. The quantity employed is very small—just enough to redden litmus paper; consequently the iron is not attacked, as indeed is apparent from the fact that the boiler has been but twice under repair.—*Scientific Review.*

New Life Belt.—A late French invention is a long bag of rubber-coated canvas, with oval wooden discs to close the ends. The interior contains two spiral springs of coppered iron wire, soldered together side by side. When closed the belt is compressed into a length of seven inches. In one of the discs is an air valve opening inwards, so that the act of extending the apparatus causes it to be filled with air. For greater safety a cork is inserted in the valve hole; which is withdrawn on closing the belt after use, the valve being opened by the insertion of the finger.

New Rivet.—A recently patented rivet has a conical point, and is headed by means of a punch with a corresponding conical cavity, around which is an annular counter-sink. This punch when placed upon the point of the rivet and struck a few blows, displaces the metal evenly upon all sides, forming a symmetrical bead.

Scientific Progress.

Possible Relation of Similar Natural and Artificial Substances.—The following paragraph is from the address of Prof. Stokes to the British Association:—"It was stated several years ago by M. Pasteur, and I believe the statement still remains true, that no substance, the solution of which possesses the property of rotating the plane of polarization of polarized light had been formed artificially from substances not possessing that property. Now several of the natural substances which are deemed to have been produced artificially are active, in the sense of rotating the plane of polarization, and therefore in these cases the inactive artificial substances cannot be absolutely identical with the natural ones. But the inactivity of the artificial substance is readily explained on the supposition that the artificial substance bears to the natural the same relation as racemic acid bears to tartaric; that it is, so to speak, a mixture of the natural substance with its image in a mirror. And when we remember by what a peculiar and troublesome process M. Pasteur succeeded in separating racemic acid into the right-handed and left-handed tartaric acids, it will be at once understood how easily the fact, if it be a fact, of the existence in the natural substance of the mixture of two substances, one right-handed and the other left-handed, but otherwise identical, may have escaped detection. This is a curious point, to the clearing up of which it is desirable that chemists should direct their attention."

Preparation of Metallic Zirconium.—M. Franz communicates to the Berlin Chemical Society the manner in which he proceeds. He fuses the finely pulverized zircon mineral with bi-sulphate of potash, washes with water to which sulphuric acid has been added, and obtains a pure basic sulphate of zirconia. By fusing this with hydrate of soda, treating with sulphuric acid and adding ammonia, pure zirconia is precipitated. To obtain metallic zirconium the partially dried hydrated oxide is dissolved in concentrated hydrofluoric acid and the clear solution poured into a concentrated solution of neutral fluoride of potassium. All of the zirconium will be precipitated as a double fluoride of zirconium and potassium. This, well-dried, is mixed with twice its weight of finely divided aluminum and exposed for four hours in a gas carbon crucible to a heat sufficient to melt copper. After cooling and breaking the crucible there will be found a regulus of aluminum penetrated throughout by parallel leaves and scales of metallic zirconium.

College of Mining and Practical Science.—Capt. Benjamin Richardson, an old Californian, has deeded New York property valued at $240,000 to Lake Forest University, Illinois, for the establishment of a College of Mining and Practical Sciences in connection with that institution. One of the conditions is that the Trustees shall within six years erect in Chicago a college building worth $100,000. Another is that they shall purchase for the institution the geological and mineralogical cabinet of Prof. J. H. McChesney. The purchase of the cabinet has already been made. It is valued at $40,000. Of this amount, Prof. McChesney donates $10,000; leaving the sum to be paid, $30,000. The collection embraces about one hundred thousand specimens.

Jargonium.—Some time since we noted the discovery, by H. C. Sorby, F. R. S., of a new earth, allied with Zirconia, for which he proposed the name Jargonia. Mr. S. now finds that he was in error; and the peculiar spectrum upon which he based his conclusion was in reality due to the presence of a very minute quantity of oxide of uranium in combination with the Zirconia. In the course of his experiments upon the subject, he discovered, that 1-50,000th grain of uranous oxide, when present along with Zirconia in blow-pipe beads, gave a spectrum equally well marked with that given by 1-50th grain of the uranous oxide alone. The mistake was therefore due to the fact that the method of investigation employed was an unexpectedly delicate test for uranium.

The Electric Light for Photo-micrography.

Brevet Lieut. Col. Woodward, U. S. A., reports from the Microscopical Section of the Army Medical Museum some experiments undertaken in order that he might be independent of sunlight for taking photo-micrographs of pathological specimens; this work being frequently interrupted, even on tolerably favorable days, by passing clouds. We quote:

"I commenced a series of experiments with artificial lights which were fortunately crowned with success, both the Magnesium and the Electric lights proving adequate sources of illumination for the production of Photo-micrographs even with the highest powers. For the production of the Electric light I used a Duboscq's lamp, set in motion by a battery of fifty small Grove's elements. I was delighted to find, as I had anticipated, that the very exaggeration of light and shadow which has prevented the Electric light from being generally adopted as a source of illumination in the preparation of photographs of the size of the object, or smaller, proved of immense advantage in the reproduction of the feeble microscopical images of highly magnified objects, and that the pictures were hence clearer and better defined than any photographs of similar objects I had hitherto seen produced by sunlight. I found also that the Electric light was so much more manageable than sunlight as a source of microscopic illumination that I could readily arrange it to produce negatives with much shorter exposures than are indispensable with the sun. The Magnesium light shared these qualities to a high degree, but I found that its best work was done when the object was not to be magnified more than a thousand diameters, and that there were certain limitations to its use on test objects. These lights are mentioned as possible sources of illumination for the production of Photo-micrographs by Dr. Lionel Beale. I am not aware, however, that any one has made successful negatives with high powers with either of these lights prior to the experiments here recorded."

The Ohio Mounds.—"The great system of mounds near Newark, Ohio, with its circles and squares, its parallel roads and tumuli, will be found on calculation to exceed in cubic contents the great Pyramid of Cheops. Garden plots are discernible and carbonized maize grains are found within the mounds, showing that they engaged in agricultural pursuits. Their implements were made of a siliceous material or horn-stone, obtained by excavation, the pits thus made still remaining. Near them are piles of chippings, marking the spots where these tools were fabricated. Some few of these implements were made of porphyry brought from a distance. For cutting instruments, as knives, and chisels, and often for personal ornaments, the native copper of Lake Superior was considerably used. * * These wonderful people, so superior to the Indian in civilization, are generally conceded to have been the ancestors of the ancient Peruvians, and of those strange people now scattered here and there through Northern Mexico and Arizona."—*Dr. Foster in Transactions Chicago Academy.*

Size of Atoms.—Sir Wm. Thomson thus concludes an article in a late number of *Nature:* "The four lines of argument which I have indicated establish, with a very high degree of probability, the conclusion that in any ordinary liquid, transparent solid, or seemingly opaque solid, the mean distance between the centers of contiguous molecules is less than the hundred-millionth, and greater than the two thousand-millionth of a centimetre. To form some conception of the degree of coarse-grainedness indicated by this conclusion, imagine a rain drop, or a globe of glass as big as a pea, to be magnified to the size of the earth, each constituent molecule to be magnified in the same proportion. The magnified structure would be coarser-grained than a heap of small shot, but probably less coarse-grained than a heap of cricket-balls."

Tungsten Blue.—This is a combination of the blue oxide of tungsten with the double cyanides of iron and tin. It is the invention of M. Tessié du Motay, and is prepared by dissolving successively in water ten parts tungstate of soda, eight of protochloride of tin, five of ferrocyanide of potassium, and one of perchloride of iron,—and agitating the mixture. The precipitate is washed, and on being exposed to the sunlight for several days, becomes intensely blue. It will not fade, and resists acids.

Mining Summary.

The following information is gleaned mostly from journals published in the interior, in close proximity to the mines mentioned.

California.

ALPINE COUNTY.

Items.—*Miner*, April 30th: Globe tunnel is pushed 10 feet per week....More men are being sent out to the Leviathan, and Prof. Rickard is expected soon to put the smelting works in order....Sacking ore at the Morning Star is to commence Monday, to continue until the whole is shipped....From the first run of the Pioneer mill on Good Hope rock, Mr. McCarty sent to Philadelphia a brick this week....Three tons of ore from M. C. Tunnel No. 3, was sent to Reno to be worked by the stetefeldt....It is expected that the new Imperial Co. will sink upon some of the other lodes belonging to the property, besides continuing the main tunnel.

Mountain.—*Chronicle*, 30th: The survey shows that the Co. has 133 feet further to run to reach the ledge.

Mt. Bullion.—Supt. Coulter has received a cable dispatch from London, directing him to push ahead with the tunnel and erect the air furnaces.

Ready.—Three tons of ore from the Pennsylvania have been brought to town for shipment to Reno.

AMADOR COUNTY.

Amador Mine.—*Ledger*, May 7th: We are informed by Mr. Faull, Supt. of the mine, that the shafts are free from fire and bad air, and they are now hoisting out the water. It is feared that it will be a long time before they can successfully work.

Oneida.—Matters at this mine were never more prosperous. They keep 60 stamps running constantly.

Butte Canal.—Work is being pushed vigorously. They have about 200 men employed.

CALAVERAS COUNTY.

Railroad Flat.—Cor. of *Chronicle*, May 7th: Work in the Petticoat mine has been suspended for the present, but arrangements are being made to sink the shaft 300 feet deeper. The mill is in the hands of Mr. Burr, who is crushing custom rock. The quartz now being stamped is from the Poe mine. There are hundreds of tons ready for milling in this vicinity. The Wet Gulch is turning out good rock from its shaft, and the vein is getting better. The Lewis Bros. are pushing their new hoisting works. The Bald Eagle mine has out an immense quantity of rock for crushing. Reynolds & Co., of Independence, are sluicing with energy. Sundermyer's claim is paying well as usual.

Sacks of it.—Cudell, Sanderson & Gray, of Railroad Flat, are taking out such rich rock that they sack it to prevent loss. The quartz falls to pieces easily, and is perfectly "lousy" with free gold.

Corral Flat.—The Co. which has been working through the old Union shaft, have abandoned the enterprise. They are now engaged in sinking a hole on the flat, with the expectation of striking the bed-rock at a depth of 125 feet.

EL DORADO COUNTY.

Uniontown—Placerville *Democrat*, May 7th: We are informed that the deposit struck by Stuckslager & Co. continues to yield a rich harvest. We have received pieces of the rock, which shows gold plainly.

Rich.—We hear of rich "clean-ups" from Pi Pi, in the southeastern portion of the county. In a few days we shall be in receipt of authentic news from there.

Still Paying.—The claims on the "Porphyry" ledge are getting good prospects, some of them rich.

Pilot Hill.—The Boulder Claim Co., after several months' run, cleaned up about $2,500.

INYO COUNTY.

Cerro Gordo.—Los Angeles telegram, 5th: Seventy-five tons of argentiferous galena, in bars, passed through here last month from Cerro Gordo; more is coming. Some 20,000 pigs are out, waiting transportation.

The Calaveras *Chronicle* has a letter from Cerro Gordo, which we quote: Outside capital must come here and erect furnaces, for which purpose there are facilities in the valley; then the country will be saved, and these mines be valuable. The present market price for argentiferous galena is; for coarse ore, $15 per ton at the shaft; for ore which is mixed somewhat with vein matter and dirt, $5 per ton. Now this ore assays from forty to two hundred dollars per ton, in silver. About two miles east of here is a silver range, from which they are taking considerable ore, which assays from $150 to $600 per ton. The market price paid by the furnace men for this varies according to assay, from $60 to $150 per ton.

KERN COUNTY:

Kernville.—Havilah Cor. Visalia *Delta*, 4th: Four White Pine boys cleaned up $2,100 from thirty tons of rock from the Jeff. Davis ledge crushed at Ellsworth's mill. About three weeks since, Chapman, Murphy and Williams cleaned up $1,410 from 38 tons taken from the Venus, and crushed at the Marsh & Kennedy mill; at the same mill, Peacock and two French boys cleaned up $1,430, from 59 tons from some ledge near the McKeadney mine. A company of German boys have commenced crushing 75 tons from small ledges near Howe's mill. All that is wanted here is labor, The gold is here. Some of the old mining pioneers in this county are returning.

LOS ANGELES COUNTY.

Soledad.—*News*, April 30th: Yesterday we were shown by Andreas Pico, a gold brick weighing 46⅛ ounces, the product of the Esgendida mine, valued at upwards of $900. Thirty-two tons lately crushed yielded $2,000.

NEVADA COUNTY.

Golden Gate Mine.—Grass Valley *Union*, May 3d: The incline is down 120 feet. The mill has 15 stamps, and crushes 24 tons every 24 hours. Hoisting and pumping done by steam. The rock crushed so far has paid the average of $30 per ton, and 200 tons have been crushed. The ledge is four inches to four feet.

North Star.—This is showing well. Rock is coming from both drifts, and 20 stamps are running all the time.

The Idaho.—Down 600 feet on the incline, but the lowest extraction of ore is 500 feet. Drifts from the 600-foot level are commenced. The number of men employed is 110. The mill has 15 stamps employed night and day.

The Wisconsin.—This has paid $7,000 per month for the last three or four months. The mine is worked under a lease.

Town Talk.—This employs 11 men, and gives a yield of $3,000 per month. Eight stamps, run by water, are constantly at work on cement.

Greenhorn.—The rock crushed in April amounted to 300 tons and gave a yield of $6,000. The company are preparing to put on steam hoisting and pumping machinery.

Empire.—The miners are down 900 feet on the incline, and are preparing to sink for the 10th level, which will put the workings down to 975 feet. There are 36 men in this mine taking rock from abandoned places, and who pay "tribute" to the company. In three or four weeks the Empire will again be working full-handed.

Badger.—This is now having steam machinery put upon it. The works will be in running order in about a month.

Union Hill.—The shaft is down 340 feet on the incline and drifts have been commenced.

New Ditch.—Same of 4th: Geo. McLean, Supt. of the Pacific Mining Co's claims, informs us that the gravel mines are actively worked on the ridge, and with satisfactory results. The American Mining Co. have recently concluded a survey for a ditch from the Middle Yuba.

Fair Play Ledge.—Same of 8th: The tunnel is now in 222 feet, and at any moment the ledge may be struck. It will give 80 feet of backs for 800 feet of ledge.

Graniteville.—At Eureka South the Mutual Co. on the "Jim" ledge are crushing rock which will give good returns. Other mines will soon start up.

Union Hill Mine.—The gold we saw yesterday from a three weeks' run amounts to a good sum over expenses.

Chalk Bluff.—*Transcript* 4th: The miners have a prospect for an exceedingly prosperous season. The South Yuba Canal Co. have brought in water for the first time in four or five years.

Washington Township.—Cor. of same, 5th: The Salathiel mine has closed. The Co. has been employing 25 men and has disbursed $2,500 per month. Dill, Slinger & Co. have a couple of ledges three-fourths of a mile from here, which are paying. Rock from them crushed at the Salathiel mill paid $15 per ton—some $25. The "Green Ledge" yielded $8 from the top croppings.

The Diamond Creek claims of Kirtley & Co. and Van Wycke are getting off more ground than usual.

Little York.—Same of 10th: The Water and Mining Co. have four sets of claims at work. They have four of Craig's monitors and are taking out $12,000 every thirty days. In all their works they employ fifty men and are running 2,000 inches of water.

The *Gazette* says the report a few days ago to the effect that Ed. Williams, at You Bet, had sold his mining claims for $55,000, to an English company, is incorrect. No sale whatever has been effected.

PLACER COUNTY.

St. Patrick.—*Herald*, May, 7th: C. F. Eaton has his shaft down 106 feet. In the last six he has taken out five tons of ore that will mill $500 per ton. When he bought the mine the shaft was down 88 feet, and the ore, from that down to 106 feet, is richer than that which McLaughlin, the former owner, took out, and it paid $300 per ton.

Ophir.—Cor. of same: The Green mine is progressing with flattering prospects. The Good Friday mine is yielding good milling rock and occasionally showing free gold. The Grass Valley Co. on the Hunter ledge are getting better prospects than ever. The St. Patrick is turning out rich ore. Crater Hill is beginning to loom up. On the Shipley ledge, Doty's ravine, John McFadden has 1,200 feet, and has milled 400 tons of quartz which averaged $16. Mr. Battis has 1,000 feet and has had several crushings that have paid him $18 per ton, and now has, at the shaft, several tons that will pay over $30. Gordon & Co. are prospecting on the Sevoy ledge and getting out a crushing that is rich in free gold and sulphurets.

PLUMAS COUNTY.

Sawpit Flat.—Quincy *National*, April 30th: The warm weather has melted the snow enough for the miners to commence washing their drift dirt. The companies have a large amount of it above ground.

SHASTA COUNTY.

Paying.—*Courier*, May 7th: Peckham's quartz mill, on Mad Ox creek, is now in good running trim, and the quartz, so far as tested, pays splendidly.

SIERRA COUNTY.

Rich Quartz.—*Messenger*, 7th: Jim Johnson has struck a ledge a mile below the camp of Rock creek, said to be one of the richest ever struck in this county, the owner having taken out 40 ounces in a short time. The ledge has not yet been prospected to any depth.

A Rich Strike.—Marysville *Appeal*, 7th: S. F. Clauser, the principal owner of the Alice Gravel mine, seventeen miles from Downieville, was here yesterday with 73 pounds bullion, valued at $30,000, the result of eleven days' run with six men. A lot of 42 pounds was sent below two weeks ago, the result of eight days' run. The mine has only been in operation two months.

SISKIYOU COUNTY.

Mining.—Yreka *Union*, 6th: The prospect is favorable for a good season. At Oro Fino the claims worked now will yield well, and water will probably last three or four weeks longer than last year. On the Mugginsville side of the mountain a large number of claims are being worked with excellent prospects.

Arizona.

Big Bug.—Prescott *Miner*, April 23d: The latest run yielded a gold brick weighing ten pounds. This amount was taken out in seven and one-half days. We were hourly expecting to hear of a much larger clean-up. Messrs. Gray and Hitchcock, the owners, started for San Francisco Saturday. We believe it is their purpose to have a forty-stamp mill put up. The future looks bright.

Walker.—The Eureka 10-stamp mill is testing matters and with good success. A clean-up will soon be made. At present matters look hopeful.

Sterling.—The test made did not give entire satisfaction. Work will probably be suspended for a short time.

Wickenburg.—The deep shaft in the Vulture ground is down 230 feet; the ledge at that depth being *twenty-seven feet thick*, and very rich. The rumor that water had been struck at the bottom was not true. The mill is running.

The owners of the White Picacho mine were jubilant. Their tunnel had reached the vein, which was found to be three feet thick. The ore is said to be very rich.

The Burro Mines.—It seems to be understood that the new mines are in Arizona. A Los Angeles telegram, of May 11th, says that parties just from Tucson confirm the reports of their richness. The ledges are from 50 to 200 feet wide. Work is brisk on the Harpending and Roberta leads. Gov. Safford had arrived. A party of prospectors report placer diggings with 50 cents to the pan.

Colorado.

Coaley and Gilpin County Lodes.—Central City *Register*, May 4th: These lodes are now the property of Mr. Breed of Cincinnati. Twenty-four men are employed. An engine with complete hoisting works is to be put up. The ore is treated at the California reduction works, and averages $160 per ton, as it comes from the mine, after throwing out the wall rock. The present yield is four tons per day. At a moderate estimate the vein of mineral must average six inches throughout.

Items.—The bottom of the deep Seaton shaft shows a two foot vein of soft mineral. ....Jas. Wright has a 10-inch vein on No. 2, East Seaton lode, which averages 100 ounces silver and 1¼ ounces gold, per ton. ....On No. 7, Larson & Bowden have at 15 feet depth a three-inch vein that assays from 200 to 400 ounces silver per ton.... An assay of ore from a pocket in the Consolidated Gregory gave 25 ounces gold and 2 ounces silver per ton, making a value of $571 Wm. Nichols has leased this mine for six months. In the 200-foot level there is a 3-foot crevice that assays from 15 to 25 ounces....The Smith & Parmelee Co. have shut down their pump. Stevens mill is crushing two cords of Bates ore a day, at a yield of three ounces per cord.

Items.—*Herald*, 4th: Robert Teats brought up four silver bricks this evening, weighing in the aggregate 2,382 ounces, worth $2,511.13. Brooks' lode at Wideawake yielded ore worth $216 per cord.

Items.—Georgetown *Miner*, April 28th: In Idaho district Fitzpatrick is averaging half an ounces a day to the hand....Work on the Whale mine and mill goes on.... Fairmount Co. have shut down their mill, and are putting in three more arastras and a concentrator....Syracuse mill is now in operation; two arastras running, and two more on Hitchcock's plan to be put in.... Stewart's new mill progresses....Collom's smelting works will start next week on 20 tons dressed Griffith ore. Huepeden & Co. are running on 2d class Terrible ore.... The east half of Junction lode has been sold to New Jersey capitalists....Workmen on the Henry Ward Beechor lode are running a cut to strike the lode lower down, where the outcrop is 30 feet wide. ....Work on the Par tunnel progresses.... A 10-inch vein struck on the Cascade lode, at a depth of 95 feet....Work is prosecuted on both ends of the Terrible lode, and the ore-house is full....Stowell & Collins, on Republican mountain, have a new pay-vein 15 inches wide, and the ore averages by assay $400 per ton.

Idaho.

The Mines.—*Avalanche*, May 7th: The Golden Chariot is now in fine shape. The lower stopes are yielding ore exceedingly rich. The Ida Elmore shute is full of rich ore. The Baxter is yielding very rich ore. A two-pound specimen presented to us is studded with ruby silver. Mr. Peck struck a rich chimney in the Potosi yesterday. High water prevents placer mining in the creek, but it is being prosecuted in Blue, Jacobs, Slaughter House and other gulches.

Northern Idaho.—Mr. Fenn brings flattering accounts of the prospects. Pierce City, Florence, Warrens Diggings, Moose creek and Salmon river will yield largely this year.

Loon Creek.—We have received a letter from Oro Grande. Parties have just commenced washing Week before last Lunday & Co. took out 25 ounces in one day's run. A nugget valued at $25 was found. The creek is rapidly rising and will cause a suspension of work for two months.

Flint.—Leviathan ore worked in Black's mill yielded $150 per ton.

Montana.

Summit.—Virginia *Times*, May 4th: Mining is brisk. Water is abundant. A. C. Hall has workmen cleaning the snow from the ditch, and will commence washing next week. The flumes of Schenck & Rositer, and Hall & Southmayde, between Pine Grove and Summit, are running day and night. The tunnel in the Midas is in 200 feet The Oro Cash tunnel is in 105 feet. $30,000 was taken out of this lead by Mr. Christnot, with an arastra, before a mill was erected. Covely Bros. are erecting a whim to pump the water out of the shaft 118 feet deep.

Items.—Helena *Gazette*, 2d: The water was let into the Big Ditch last week. Taylor & Thompson started their mining Saturday. Mr. Getchell starts up to-day.

Philipsburg.—Cor. of same: Although the mill has stopped, the camp is as well thought of by property holders as ever. It is not improbable that another mill will be erected upon an improved plan. Work in the mines goes on with the same energy, and will continue through the season. It is thought, too, that the stoppage of the mill will be only temporary.

Butte and Rocker.—Deer Lodge *Independent*, April 30: The miners have got fairly at work. The ditches are not all full, but will be by the end of next week.

Pike's Peak and Pioneer.—Water was turned into the ditch Tuesday. The prospects were never so bright as at present.

Silver Bar.—The water strike continues.

Nevada.

COPE DISTRICT.

Mountain City.—Cor. of Elko *Independent*, May 7th: California hill has turned out the richest of our camp. Within the past week five distinct ledges have been struck, and with one or two exceptions they are the richest yet. The Co's 10-stamp mill started up day before yesterday. The owners have contracted to crush 200 tons of Argenta ore. The mill and mine give employment to a large number of laborers. Times are brightening. The Canty mill is not running owing to some misunderstanding among the owners. Work is being prosecuted by the Argenta and Mountain City. The Fuller Co. are working two sets of hands on the Mammoth and Great Eastern mines, and have out over 600 tons of ore, which assays from $38 to $647.08 to the ton. The Pride of the Wide West, worked by Mr. Handy, looks better than ever. They are taking out large quantities of ore. The Sultana is being worked with energy, as well as the Great Republic, Capital, Virginia and Oregon. The placers employ a large force of Chinamen as well as whites. They pay from $4 to $10 per day to the hand. Russell gulch is being worked throughout its entire length.

Mining Sale.—Thirty-five hundred dollars were paid, on Thursday, by Pago, of San Francisco, to one of the locators of the Mountain City mine, for an interest. The company will put up reduction works.

HUMBOLDT.

Unionville.—Telegram of May 9th: In the case of the Silver Mining Co. vs. Manitowoc and Arizona mine, owned by Fall & Temple, the verdict was given in favor of defendant yesterday. It is estimated that over a half a million dollars are in sight in one drift. Work will be resumed by Jno. C. Fall.

WASHOE.

Yellow Jacket.—Gold Hill *News*, May 7th: The horse at the 900-foot level turns out less extensive than was feared. The drift north at the track floor has passed entirely through it, and is now in good ore again.

Hale & Norcross.—Daily yield 175 tons. The mine is looking extra well, especially at the lowest level. At this point the north drift is in nearly 100 feet from the shaft, in fine pay ore all the way.

Chollar-Potosi.—Daily yield 145 tons. The ore-producing sections are all yielding well, especially the old Blue Wing.

Ophir.—The ledge is not yet reached in the lower drifts. The south shaft in the surface workings yields 30 tons of fair ore per day.

Kentuck.—Yielding 50 tons per day of fair ore, principally from the upper levels.

Overman.—Yields 150 tons daily.

Occidental.—Grading for the foundation of the new mill is commenced.

Bullion.—Active operations resumed day before yesterday, with Geo. Moch, Supt. They have commenced drifting north at the 500-foot level.

Belcher.—The face of the drift at the 730 foot level, going south, looks more promising.

Crown Point.—Daily yield, 65 tons of low grade ore from the upper levels. The incline from the 1,000-foot station is 70 feet deep. The rock is hard, but favorable for blasting.

Hope.—The lower level is looking better and the general yield of the mine averages over $25 per ton. Both mills are running steadily.

Virginia Consolidated.—The west drift at the 500-foot level is in 327 feet from the shaft. Rock favorable and good progress made.

Sacramento & Meredith.—The mill will be reducing ore inside of two weeks.

Sierra Nevada.—The surface deposits still give their regular yield, and the mill is running.

Segregated Belcher.—Daily yield 30 tons. Mine looking well, and ore yielding better.

Telegram, 10th: The body of ore lately developed on the lower level of the Hale & Norcross mine is very extensive and rich.

WHITE PINE.

Review.—*News:* The old mines are nearly all full manned again, and work is commencing on many new claims. A general clearing of grounds is in process. Treasure Hill is getting to be lively. The Bullion shipment for the week ending May 2d was $45,681.74—of which $22,367.23 went to San Francisco, and $21,314.51 to New York.

Items.—The first 14 days of the second run of the Stanford mill turned out $30,325. Earl works in Aurora Consolidated are yielding a large quantity of $60-ore. Black Cloud, near the Eberhardt, is developing finely. The ledge is over 20 feet wide, and well defined. Montauk is attracting a good deal of attention. Montrose is to be developed by the San Francisco owners. Silver Vault tunnel in 155 feet. Fireside dump has 70 tons of ore ready for shipment. The Hemlock, Constitution, Watson, Dell and Wabash mines have been consolidated, the company to be known as the Hemlock and Wabash Consolidation. The company will be incorporated in San Francisco, and will commence work on a large scale immediately. Bob and Tom Hannegan have opened the Elko into one of the most valuable base metal mines in the State. Yesterday they struck it rich in the Austin, 1,600 feet north, two foot vein, $200 ore. We were shown some rock from Clifton district which assays $600 in gold and $400 in silver to the ton.

Alsop Smelting Works.—A leak was discovered on the 5th and the work stopped. The run was 34 days; and but for the crack, was good for as many more. The tunnel was still sound. The yield was 157 tons of bullion.

Silver Park.—Cor of same: Ferguson's 12-stamp mill started up on April 29th. The mines now open number about 50. The Bradshaw and Conway is the main attraction. The face shows a body of rich ore 16 feet wide. They have out 30 tons of first-class ore. The Nevada Queen has an incline down 60 feet, and 120 tons are on dump. Forty of this will go $150 to the ton. The Magnolia has 70 tons good ore out. The Liberty has out 60 tons which will work $150 without assorting. The Miners' Delight has 30 tons which will work $400 per ton.

Ely.—The Pioche Co. have upon the surface a large amount of extraordinarily rich ore. They have the site for the mill graded, and all of the machinery will be on the ground by the 8th of May. The Burke has a 50-foot shaft down, and the Co. are raising ore enough to supply the 5-stamp mill also belonging to Ely & Raymond. Excelsior shaft down 30 feet. American Flag has out from 60 to 100 tons of ore, like that of the Pioche. It is owned by Jackson & Co.

Yellow Pine.—A Los Angeles telegram says smelting works similar to those at Cerro Gordo will be put up at the Comet mine. The Tulare *Times* of 7th of May says: A large delegation of our citizens are about starting for Yellow Pine. Teams carrying their freight have already gone.

A Hamilton telegram of 10th says: The bullion shipments for the past week foot up $54,690, being $9,108 in excess of the previous week's shipments. Of this amount $33,275 went to San Francisco, and $21,513 to New York.

New Mexico.

Mining.—*Press and Telegraph*, April 30th: There is general activity in this immediate vicinity on Spanish bar, Grouse and Humbug gulches, and also in the bed of the Moreno, and but few miners idle about the city.

The Chester mill will soon be put permanently at work quartz crushing.

Microscopical Society.—This new society held another preliminary meeting this week. On the 23d inst. the regular monthly meeting will be held, and the organization completed. This will be followed by regular monthly receptions, when invitations will be extended to those interested in this branch of science.

San Francisco Mining Stock Market.

The mining share market has been characterized by a a lessened activity during the period under review, and that under well maintained prices, with the exception of a single leading stock. The speculators apparently command the situation, while outside dealers are inclined to keep aloof, awaiting their time for better opportunities to make judicious investments. The dullness of business generally also has its influence to prevent the latter class of dealers from entering the market at present.

The White Pine *News* of the 9th inst. remarks as follows: "The mines being worked continue to look well, although no material changes have taken place within the past week, except in a few instances in base metal. Under improved condition in appearance, both the Hidden Treasure (original) and Noonday have reduced their working force. Aurora South has increased. The Aurora Consolidated continues its light force, while the Eberhardt has reduced, thus creating the impression that possession of these two mines will soon be given to the new purchasers. The Tom Paine mine has been sold in Chicago, on terms similar to those negotiated for the Pogonip and Othello, (the original owners retaining a large portion of the stock, and the purchase-money has been forwarded through the National Bank of Commerce. The Hemlock, Constitution, Watson, Dell, and Wabash mines, taking in the oldest titles and about one-half the area of Pogonip Flat, have been consolidated under the name 'Hemlock and Wabash Consolidation,' and will be incorporated in San Francisco at an early day. A party of San Francisco capitalists has already thrown out a 'feeler' for the purchase of the entire claim of the Consolidation, together with the Consolidated Combination mine on Chloride Flat, thus securing a belt from the Noonday on Bromide, across the entire width of Chloride and Pogonip Flats. Our bullion shipments for the week foot up $54,790, being $9,108 26 in excess of the previous week's shipment. Of this amount, $33,275 62 went to San Francisco, and $21,514 38 to New York."

Hale & Norcross—has been in moderate request. The amount of ore extracted during the week ending May 7th, amounted to 1,053 tons, 351 tons coming from the upper mine, and 702 tons from the lower mine. During the same time, they delivered 1,337 tons to the mills, leaving 6,522½ tons on hand in the dumps. On the 7th inst. the winze from the sixth station was down 91 feet, and it is reported that it still carries excellent ore. The extensive opening on the seventh station shows a body of ore "surpassing in extent and quality any ever before found in the mine."

Gould & Curry—sold largely at a rapid decline. For the week closing with May 9th, 580½ tons of ore were extracted, showing an average assay value, from car samples, of $43 34 per ton. The new Superintendent reports as follows: In cross-cut No. 3, running west, on the seventh station, they had made five feet up to May 3d, when they stopped, having encountered hard porphyry and quartz. In cross-cut No. 1, work was recommenced on the 4th, carried through eleven feet of quartz, and is said to be improving. On the second station, the raise to 100 level progressed thirty-five feet, through vein matter. On the 7th inst. they commenced sinking on the El Dorado chamber, and made fifteen feet through quartz with ore in sight. In the Potosi drift, on the El Dorado level, they advanced forty-eight feet through vein matter; and the southeast drift, on the middle adit, has been carried thirty-four feet through the same material. During the month of April the bullion yield amounted to $48,722 against $50,213 in March.

Chollar-Potosi—was in less favor than during the previous week. During the week ending May 6th; 1,069 tons of ore were extracted, showing an average assay value of $55 62 per ton; previous week, 1,022 tons were extracted. The various faces in the Blue Wing stope are all in good ore, and producing largely. The Belvidere section has been extended south from the main stope 140 feet, showing no depreciation in quality of ore taken from the extreme south portion. In April the bullion yield aggregated $130,361; in March it was $113,189; and in February, $91,545.

Overman—has been in good demand. During the week ending May 7th, extracted 831 tons, showing an approximate value of $11,134, equal to $14 60 per ton.——**Sierra Nevada** sold to a considerable extent. For the week ending May 7th 427 tons of ore were taken from the gravel deposits.

Imperial—has been largely dealt in at an advance. A letter of the 10th states that the winze looks favorable, the ore being two feet wide at the bottom. No change in the southwest drift, or on the 1,200 level. An assessment of $5 per share was levied on the 7th inst.——**Segregated Belcher** is dull of sale. About 40 tons of ore are taken out daily, showing a car assay value of $45 per ton. More will be taken out so soon as milling arrangements are perfected.——**Ophir** levied an assessment of $5 per share on the 6th inst. Nothing of importance from the mine.

Crown Point—continues to be well maintained, under considerable sales. During the week ending May 6th, 275¾ tons of ore were mined, showing an assay value of $4,368 37, or $15 84 per ton. The bullion yield for the month of April amounted to $19,680, being the product of 1,572¼ tons of ore.——**Kentuck** is in rather limited request. For the week closing May 6th, 282 tons of ore were extracted, valued at $4,839 40, equal to $17 35 per ton.——**Savage** sold quite largely. The bullion product for April amounted to $6,300; in March it produced $23,030; and in February $7,035.——**Aurora Consolidated**, (W. P.) levied an assessment of $4 per share May 7th.——**Noonday**, (W. P.) levied an assessment of 30 cents per share, on the 10th inst.—*Commercial Herald.*

The Root Blower.

We have received a communication from Messrs. Keep & Bargion, manufacturers of the Root blower, who think that injustice was done their machine in the extract on the Sutro tunnel from the N. Y. *Engineering Journal*, which we published in the Press of April 30th. They object more particularly to the paragraph which reads: "As for ventilation, it is well known that the use of the Root blower has become indispensable in the deep mines; and it has been asserted that the artificial ventilation so produced has dried the timbers underground, so as to make them very combustible."

We are unable to see any injustice in these remarks; if anything, there is quite a compliment to this blower. The manufacturers deny that timbers have been found to be rendered more combustible by "artificial" than by tunnel ventilation, in regard to which point, no positive assertion, but rather a suggestion, is made in the article in question. Whether it be true or not, we cannot see how it injures the blower, nor how it will make the slightest difference to the interests of the manufacturers. The mines must be ventilated, and if this can be effected better or more economically by the use of the blower, this machine will be employed. It would appear that but one small Root blower was used in these mines before the fire; but this fact has no material bearing on the question, as the article was an argument *for* the Sutro tunnel and not *against* blowers; and, moreover, all which is stated would be as true if any other blower were used. And we may here remark that since the fire some thirty or forty Root blowers have been introduced into this very locality.

The Root blower is certainly a most excellent and efficient machine, which is coming very extensively into use. If our readers will turn to page 188 of the present volume, they will find an illustration of the largest one of the kind yet made, which is used for propelling the cars in the New York pneumatic tunnel. At the Amador mine, after the late fire, one was used for exhausting the gases produced by the conflagration, and the superintendent was so well satisfied with its work that he immediately ordered another, and by means of these has been able to clear out the mine so that operations can now be carried on. It is widely known, both at the East and West, and needs no particular recommendation; but we are cordially ready to testify in its favor at any time.

Farming and Gardening.

Communications for this department are solicited from all parts of the Pacific States and Territories.

Trees and Temperature.

Our readers will recollect the paragraph in one of Mr. Greeley's late articles in reference to the effect of some evergreens which he had planted on his farm—he found they had increased the average temperature, in their immediate vicinity, several degrees. There is no doubt about the fact.

We have now the record before us of a farmer in Canada who, from the exposed situation of his grounds, was unable to raise fruit with any reasonable degree of success. Having a love for trees, but without expecting any direct benefit from them, he spent much of his leisure for two or three years in setting out shade trees around his house and along the lanes and roads passing through his farm. He was much surprised, after his shade trees had reached a somewhat extended growth, to observe that his fruit trees commenced to improve in bearing, which improvement continued until now they are yielding abundantly. Verily the planting of trees "tempereth the winds" and the climate to the tender herb and vines within reach of their protection.

We have no doubt but that many such examples might be found, if the attention of farmers was more generally called to such facts as the above.

The coast range of California, where it is often found exceedingly difficult to raise fruit, on account of the bleak ocean winds, and many localities in our sister State of Nevada might be immensely improved in the matter of temperature and shelter from winds by the cultivation of forest trees, to say nothing about their advantage in the production of moisture. Although much has been done in that direction the past season, the number of trees set out is far below that which should be reported. A double profit may be derived from forest trees—triple in fact. They will pay for their fruit alone, and again for their climatic advantages, and after that for their timber. Every farmer who has any leisure on his hands (and what farmer in California has not) should make all due preparations, this summer, to plant trees the coming winter and spring. It is a business which is in no danger of being overdone. It would not be overdone if one-fifth of all the arable land in the State was thus covered with a judicious selection of forest trees.

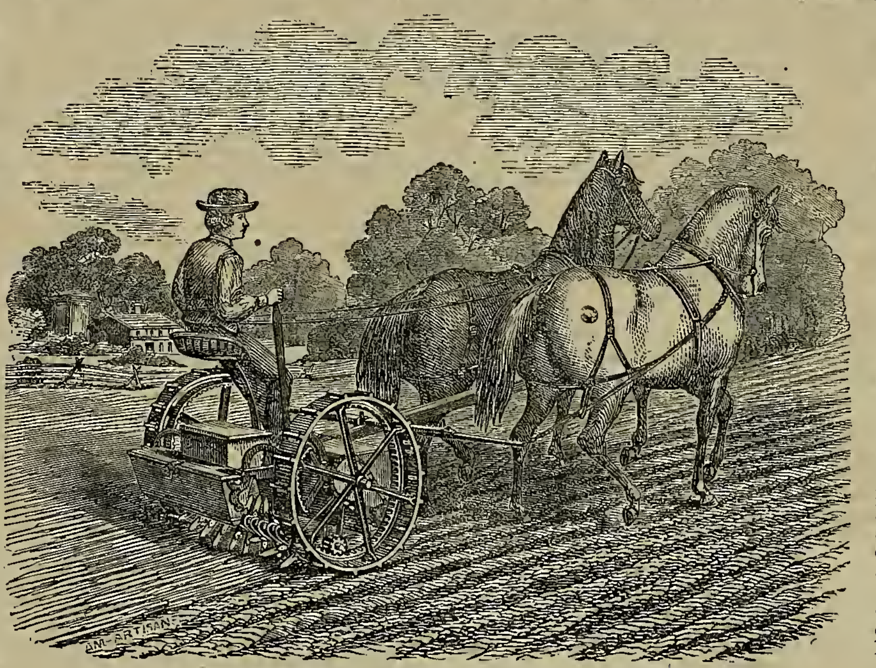
Orange Culture.—Oranges, at present prices, when grown convenient to a market, are susceptible of producing more money to the acre than perhaps any other agricultural product, requiring equal care, which can be raised. Orange trees at ten years of age ought to be able to produce 5,000 oranges each; and as 60 trees can easily be grown on a single acre, it follows that a tract of land in orange trees at mature growth is capable of producing, at half a cent only for each orange, $1,500 to the acre. What crop will do better than that? and how can the crop fail of realizing the price named? Pine apples and bananas, which might be readily produced in the southern portions of the State, will yield quicker returns. They might probably be made to yield equally good returns in three years.

Practical Knowledge in farming is of paramount importance; but the right application of scientific facts and principles has done, and is doing, more to advance agriculture, than all the traditional and empyrical knowledge that could be accumulated to the end of time. Practical and scientific knowledge should go hand in hand on the farm.

Revolving Sulky—Harrow and Seeder.

We present our agricultural readers with an illustration of a device which comes to us with good recommendations. It was invented in Maryland, and has taken a first-class premium and gold medal at the late Agricultural State Fair in that State. It is stated that it has stood thorough working tests with great success, and that it does not easily get out of repair, while it is so simple that it can readily be managed by a boy.

This apparatus answers the purposes both of a harrow and of a seeding machine. It requires no other preparation of the land than that of plowing, and is able to work over from ten to fifteen acres daily. It will work on hilly or level, stony or clean land, being so constructed that there can be no side motion on hill-sides, while wooden pins in the sockets protect the teeth from being injured by rocks or roots. In the front box are carried the fertilizer and grain, and in the rear the grass seed, all of which can be sown collectively or separately, or the revolving harrow can be worked alone, these distinct parts being thrown in or out of gear by means of a foot lever. There is a tool box under the driver's seat. By means of thumb-screws the quantity of fertilizers or seed can be easily regulated; and the harrow can be raised or lowered by means of the lever at the right hand of the driver.



TAVEAU'S REVOLVING SULKY-HARROW AND SEEDER.

The harrow is revolved at a high speed by the gearing in the traction wheels operating on its shaft, and reduces to fine particles the rough clods. A spring-toothed comb, which plays between the harrow teeth, scatters all trash, leaving a smooth even surface. The working of the machine is highly spoken of in several papers.

The inventor of this machine has also patented a sulky gang plow, which may be used to precede his harrow and seeder. He has likewise a steam plow combined with a harrow and seeder, by means of which the ground can be plowed, harrowed and sown at one operation. His steamer unites cable traction with field traction, somewhat after the English plan. The engine is also arranged to perform the functions of a steam road roller or road traction engine, and is furnished with appropriate pullies for driving farm or any other machinery.

The sulky-harrow and seeder was patented in May, 1869, and the steam plow in March, 1870, by Augustus L. Taveau, Chaptico, St. Mary's county, Md., to whom or to R. Sinclair & Co., 62 Light street, Baltimore, Md., application for further information, or for the purchase of State rights, may be made.

The Crops in Alameda and Santa Clara.

My own observations on the hay and grain crops, this season, have reference only to the counties of Alameda and Santa Clara, as I have not been outside of those limits.

Wherever the subsoil is filled with water, as it is on the adobe flats around the bay, and where irrigation and overflow have had effect, the grain looks finely. The adobe flats always produce abundant harvests when the drouth is severest elsewhere; while a command of water for irrigation is an assurance often too little regarded, but most highly prized by the considerate farmer.

There is a range of good grain land among the hills at about 500 feet elevation, where the fog clouds refresh the thirsty plants and cool the condensing soil. In the driest seasons the hovering fogs insure the crops; but in wet seasons there is an injurious surplus of moisture. Below the fog line and above the moist soils of the bay lands light crops may be expected.

This season, throughout a large extent of country, on such lands as depend for moisture upon the fall of rain, unless immediate showers refresh the famishing fields, the coming crops will be either very light or a total failure.

Of course, the time of sowing and manner of cultivating has had its effect. Some of these I will remark: The earliest sown grain generally looks the best, although the cold and frosts have kept it back; but volunteer grain is very short indeed, in some cases not even fit for hay. This may look like a contradiction; but facts are never contradictions when understood. Lands that were plowed deep show the best prospects. And here is another contradiction to the former experience of grain-growers in California. But this can be accounted for very simply. The rains this year have not saturated the subsoil by copious, long-continued soaking storms, as has been the case on this coast, in past years; but it has come down in showers of shorter duration, and has been followed by drying winds that have evaporated the moisture from the surface. Thus the subsoil becomes the reservoir of water for the growing crops which are supplied after the rains cease, by capillary action and the deep-searching pump roots of plants. The subsoil has not received its customary supply, and the growing annuals are left to depend upon the surface supply alone.

Lands that were deeply plowed early in the season, have absorbed and retained more surface water than those that were plowed shallow, or not at all. This will account for the present exception in deep plowing for grain.

But when from any cause the ground is filled with water, and the growing crops are to depend largely or entirely upon the water so collected, unless the supply is unlimited, shallow plowing is the best. And for this reason the portion of soil loosened up by cultivation soon dries out, and is of no use except as a mulching, to protect the moisture in the undisturbed soil beneath from the sun and drying atmosphere.

A shallow protection is, in such case, better for the roots than when the soil dries deeper. If the roots are all below this soil mulching (for on drying it really becomes a mulching), they are not dried up in the disturbed soil, as must happen when rooted in, instead of below, such loosened soil. Besides a greater supply of moisture and a spread of roots in the undersoil nearer the surface—a matter of no small importance—is most surely the result in this, a common case in California.

Where the growing crops are occasionally refreshed, and the surface soils moistened by cooling showers, as in the Eastern States, and where kept wet by irrigation, this shallow plowing would be ruinous. The roots are there encouraged to feed near the surface, while here they search deep for subsistence beneath a parched surface.

An occasional summer fallowing—plowing deeply—will recuperate the soil, and if thoroughly cross-plowed through early summer, the foul weeds may be killed out, that shallow plowing and constant cropping produces.

Last year a plentiful supply of soaking rain gave promise of abundant harvests; but a few foggy mornings, followed by a burning sun, caused the cryptogamic "rust" to attack the wheat fields, and many farms throughout the coast country about the bay suffered the loss of the entire crop. It weakens one's faith in old proverbs when he that sows cannot reap. I was in Sierra Valley last summer when a fury of hail dashed many a field of headed grain to the earth. The next day, at noon, some of the hail still remained unmelted. But failures and calamities, if meekly borne, are never curses—if vigorously surmounted, amount to triumphant good.

If farmers cannot prevent the rust nor the destruction of storms like this, they can, at least, obviate many difficulties now encountered—can follow a more diversified, and, consequently, a surer method of farming, can more intelligently conduct their business, and more economically use their time and husband their resources.

Some of the parties that ruthlessly burned their straw stacks last year will wish them within reach of their stock before the harvest of 1871, if the present drouth continues. Hundreds of herds of stock are starving in this State; thousands of animals will be killed, that a few may live upon the scanty ranges; and yet the majority of grain growers, all over the State, *burn their straw every year*. This is a practice that will be made a crime against the State if there is honesty in the next Legislature to pass such a bill.

A sheltered straw stack, six years old, is better relished by stock than new straw, and is just as nutritious.

When from twenty-five to seventy-five tons of vegetables can be cheaply grown on an acre of land under ordinarily favorable conditions, and when these vegetables, which the farmer may produce, fed with the straw now burned, will keep many head of cattle from starving; will fatten them for the market when beef, from natural pastures is poor, and when no sensible farmer dare deny this statement, is it not time, in the course of events, to do something?

In order that the people may have beef it is not necessary that herders should monopolize half of creation to pasture mustang stock on, any more than it is necessary for a man to sow a thousand acres of grain to make a living by farming. The sooner this country is divided up into farms that can be utilized for homes, and which can be thoroughly, economically and intelligently managed by the prudent husbandman, the owner thereof, the better will it be for all concerned. Every man that can raise anything, can profitably keep stock. Taking into account the expense of money and labor attending stock growing of all sorts, there is more profit in it to the farmer, all over the United States, than in any and all other products. I have read the statement that the hay crop of New England was of more value than the cotton of the South. How much is the straw crop of California worth? Surely nothing unless it is economized—much if converted into animal food and usefulness.

S. H. Herring.

Fort Sumter is being rebuilt.

A Comforting Use of Flowers.

A lady communicates to the *American Agriculturist* the details of an incident, showing how the beautiful though silent language of flowers may be made to speak volumes of tenderness to the bereaved and sorrowing heart. We re-write as follows: A loving mother had lost a little child, and a universal desire was manifested, among her friends, to relieve the mourning family by any possible means of words or deeds. Generally, in such cases, words lose their force, and loving and thoughtful hands are at loss how to best manifest their kindly offices. On this occasion a sympathizing and thoughtful lady had the ground around the grave and the grave itself covered and lined with properly arranged evergreen boughs. Tastily interwoven therewith were innumerable numbers of exquisite flowers, secured to their places singly or in tiny boquets with hidden fastenings. The usually unsightly mound of fresh-turned earth was converted into a beautiful bed of evergreens and flowers. The entire effect of the arrangement was beautiful, appropriate and unique; but who can tell its subduing influence upon the weeping and surprised mourner, as with family and friends she approached the spot, and saw her darling little one laid away, as if to sleep, in that beautiful bed of blooming fragrance. No yawning grave was there; no unsightly sexton approached, with vulgar and cruel spade, to bury in the cold damp ground the form which was sleeping so quietly, so prettily, in its tiny casket. The single symbolic handful of earth dropped softly, by the beloved pastor, fulfilled its purpose far better than the spadeful usually lst fall, heavily and unseemingly, by the unfeeling and unsympathizing assistant, who usually officiates on such occasions. A more appropriate, touching or comforting use of flowers could scarcely be devised.

Flowering of a California Pitcher Plant.

A specimen of this beautiful plant, the *Darlingtonia Californica*, which this State has recently contributed as something new to the world, has recently bloomed in New York. This, the *American Agriculturist* thinks, is the first instance in which this plant has presented a bloom, under cultivation. It flourishes and blooms freely in many parts of this State, especially in Nevada county, around Moore's Flat. It was first discovered, however, near Shasta Peak. It grows in wet, marshy localities; but although it likes wet at the roots, it nevertheless appears to require good drainage. The conditions of its artificial cultivation are not yet perfectly known; hence, although a great number of specimens, both from the roots and seed are growing both in the Atlantic States and Europe, the above is thought to be the first instance in which it has bloomed abroad. So little is known abroad of its habits, and so difficult is its cultivation, that as yet it remains one of those rare floral gems which can be found only in such collections as are under the charge of gardeners of the highest skill in their profession.

We propose, at an early day, to give a pictorial representation of this interesting plant, which, by the way, contributes an undoubtedly new genus, represented, we believe, as yet, by this single species only. Possibly it may have no companion; but from its peculiar character, continue forever apart from all other species in the floral world, as do the cameleopard and the flamingo, in the animal kingdom—forming a genus by itself.

Mignonette.—For the benefit of our lady readers, who take an interest in floriculture, we reproduce from the Agricultural Reports the following extract relative to the above fragrant flower plant:

The mignonette in its native country, Barbary, is a shrub, and not an annual, as with us. It should always be sown in light, sandy soil, as when sown in a stiff soil it loses its fragrance. To obtain the tree mignonette, a vigorous plant from the common kind, sown in April, should be chosen, put into a pot by itself, and all summer the blossom buds to be taken as fast as they appear. In the autumn the lower side shoots must be taken off so as to form the plant into a miniature tree. It may afterward be transplanted into a large pot, with soil formed of sand and turf broken into small pieces. The plant should be kept in a warm room all winter, regularly watered every day, and in the spring the stem will begin to appear woody. The second summer the same treatment should be observed, and the following spring it will have bark on its trunk and be a complete shrub.

Transportation of Eggs.—Now that the means of intercommunication between the various parts of the coast are being increased and improved, and thus farmers are enabled to bring more and more of their productions into the market, it is becoming more and more necessary to have improved methods of packing the transported articles. We have been shown some boxes for eggs which are said to serve their purpose excellently well, and we saw some eggs from Oregon which had lately arrived in them in very good condition. The boxes are the Stevens Bros. patent, and are to be seen at 210 Clay street. They are said to be coming into quite general use, and to possess several advantages beside that of keeping the egg sound and good. Just thirty dozen eggs can be put into one box; and hence, while there is no necessity of counting (and this trouble can be saved, as a glance will show whether the proper number are in the package), it also avoids the possibility of dispute on the point between farmer and commission merchant; for each egg has a separate compartment, and if every compartment is filled, there are no more or no less than thirty dozen in a box. Messrs. John Gray & Co., produce and commission merchants, No. 210 Clay street, are willing to send to farmers, who deal with them, these boxes without charge. They do so because they, themselves, as well as the farmers, are gainers thereby, saving in time and trouble besides in the breakage and loss of eggs.

Liquid Grafting Wax.—This is a substance which is often very convenient and necessary for use in fruit orchard and vineyard, The *Country Gentleman* gives the following receipt for making it: Melt one pound resin gently, then add one ounce of best tallow; stir it well, take it from the fire, cool off a little, then mix with it one table spoonful of spirits of turpentine, and add seven ounces of alcohol, 95 per cent. proof; this will cool it down so rapidly that it will be necessary to put it over the fire again, stirring it constantly, taking care that it does not inflame; remove from the fire as soon as the lump begins to melt again, and continue stirring until thoroughly mixed. It will appear like strained honey. After setting the scions, apply a thin coating with a small brush; the wax will then harden, and is impervious to air and water. Use a kettle large enough, so that it will not foam over when you put in the alcohol, which should be poured in gradually.

The Sacramento Valley.—There are principalities in Germany where civil government is maintained, and all the pomp of a court kept up on a much smaller extent of territory than the Sacramento Valley. The inhabitants of New England can with difficulty conceive of a valley forty miles wide. The dwellers by the Mohawk and the Shenandoah can have just as little comprehension of it. The valleys of the Rhine and the Rhone are insignificant in point of territory when compared with it. And we have just as little idea of the cultivation of their valleys as they have of the extent of ours. Can we not learn a lesson of each other? *Our* lesson is that the most magnificent natural advantages are nothing unless we improve them. *Their* lesson is not to remain clinging to the scanty acres of Europe, but to take up their march for the New World.—*George Barstow, before the Chico Agricultural Society.*

What I Know of Farming—No. 17.

Commercial Fertilizers—Gypsum.

Prices vary so widely in different localities that no fertilizer can be pronounced everywhere cheapest or best worth buying; and yet I doubt that there is a rood of our country's surface in fit condition to be cultivated to which gypsum (plaster of paris) might not be applied with profit. Where it costs $10 or over per ton, I would apply it sparingly—say, one bushel per acre—while I judge three bushels per acre none too much in regions where it may be bought much cheaper. Even the poor man who has but one cow should buy a barrel of it, and dust his stable therewith after cleaning it each day. He who has a stock of cattle should never be without it, and should freely use it, alike in stable and yard, to keep down the noisome odors, and thus retain the volatile elements of the manure. Every meadow, every pasture, should be sown with it at least triennially; where it is abundant and cheap, as in Central New York, I would apply it each year, unless careful observation should satisfy me that it no longer subserved a good purpose.

As to the *time* of application, while I judge any season will do, my present impression is that it will do most good if applied when the summer is hottest and the ground driest. If, for instance, you close your haying in mid-summer, having been hurried by the rapid ripening of the grass, and find your meadows baked and cracked by the intense heat, I reckon that you may proceed to dust your meadows with gypsum with a moral certainty that none of it will be wasted. So if your corn and other fall crops are suffering from and are likely to be stunted by drouth, I advise the application of gypsum broadcast, as evenly as may be and as bounteously as its price and your means will allow. I do not believe it so well to apply it specially to the growing stalks, a spoonfull or so per hill; and I doubt that it is ever judicious to plant it *in* the hill with the seed. The readiest and quickest mode of application is also, I believe the best.

How Gypsum Impels and Invigorates

vegetable growth, I do not pretend to know; but that it *does* so was demonstrated by Nature long before man took the hint that she freely gave. The city of Paris and a considerable adjacent district rests on a bed of gypsum, ranging from five to twenty feet below the surface, and considerable disintegrated in its upper portion by the action of the water. This region produces wheat most luxuriantly, and I presume has done so from time immemorial. At length, it crawled through the hair of the tillers of this soil that the substance which did so much good fortuitously, and (as it were) because it could not do otherwise, might do still more if applied to the soil, with deliberate intent to test its value as a fertilizer. The result, we all understand.

Gypsum is a chemical compound of sulphur and lime—so much is agreed; and the theory of chemists has been that, as the winds pass over a surface sown with it, the ammonia which has been exhaled by a thousand barn-yards, bogs, etc., having a stronger affinity for sulphur than lime has, dissolves the gypsum, combines with the sulphur, forming a sulphate of ammonia, and leaves the lime to get on as it may. I accept this theory, having no reason to distrust it; and knowing that sulphate of ammonia is a powerful stimulant of vegetable growth (as any one may be assured by buying a little of it from some druggist and making the necessary application), I can readily see how the desired result *might* in this way be produced. For our purpose, however, let us suffice that *it is* produced, of which almost any one may be convinced by sowing with gypsum and passing by alternate strips or belts of the same clover-field. I suspect that not many fertilizers repay their cost out of the first crop; but I account gypsum one of them; and I submit that no farmer can afford not to try it. That its good effect is diminished by many and frequent applications, is highly probable; but there is no hill or slope to which gypsum has never yet been applied which ought not to make its acquaintance this very year. I am confident that there are pastures which might be made to increase their yield of grass one-third by a moderate dressing of it.

I have heard Andrew B. Dickinson, late of Steuben county, and one of the best unscientific, unlearned farmers ever produced by our State, maintain that he cannot only enrich his own farm but impoverish his neighbors' by the free use of gypsum on his woodless hills. The chemist's explanation of this effect is above indicated. The plastered land attracts and absorbs not only its own fair proportion of the breeze-borne ammonia, but much that, if the equilibrium had not been disturbed by such application, would have been deposited on the adjacent hills. As Mr. D. makes not the smallest pretensions to science, the coincidence between his *dictum* and the chemists' theory is noteworthy.

Now that our country is completely gridironed with canals and railroads, bringing whatever has a mercantile value very near every one's door, I suggest that no township should go without gypsum. Five dollars will buy at least two barrels of it almost anywhere; and to barrels may be sown over five or six acres. Let it be sown so that its effect (or non-effect) may be palpable; give it a fair, careful trial, and await the result. If it seems to subserve no good purpose, be not too swift to enter up judgment, but buy two barrels more, vary your time and method of application, and try again. If the result be still null, let it be given up that gypsum is not the fertilizer needed just there—that some ill-understood peculiarity of the soil or climate renders it there ineffective. Then let its use be there abandoned; but it will still remain true that, in most localities and in countless instances, gypsum has been fully proved one of the best and cheapest fertilizers known to mankind.—*Horace Greeley.*

Sulphur for Grape Mildew.—The vineyards of France seem, to a great extent, to have recovered from the "odium," as it is called there, which at one time threatened to nearly ruin the vine in some of the departments. The remedy applied was sulphur, as used here. The "odium" is a species of the mildew, and if not identical with that which attacks the grapes of this country, is certainly very similar to it, and of the same cryptogamous nature.

In the application of the sulphur, the De Verges bellows is the implement used there, in which a pound of sulphur is placed at a time. Much practice is required to eject the sulphur skillfully, so as to cover with the dust the entire surface of the stems and leaves. Application is made then in the same manner as suggested by our correspondent two weeks ago;—first, at a season just preceding bloom; second, just following the last bloom; third, when the fruit is two-thirds formed.

To Neutralize the Acid of Fruit in Cooking.—The acid in fruit pies may be neutralized by adding to each as much carbonate of soda as will cover a 25-cent piece. This simple precaution, which does not affect the flavor of the fruit or impair its healthiness, saves much sugar, otherwise needed to render the fruit palatable.

Notices to Correspondents.

A. J. B., Treasure City.—Bismuth is used principally for forming alloys with other metals, and is consumed, probably, in far greater quantities in Birmingham, England, than in any other place, although used in considerable amounts at the East, in the manufacture of the so-called Brittania ware. It is also used in casting type on account of its alloys filling the molds (instead of shrinking) on cooling, and it enters into the composition of various other alloys, which, in general, it renders more fusible. Its oxide is used in certain cosmetics and medical preparations. Still, the total amount produced is comparatively small, and its price is often, to a great extent, speculative, depending on the amount in the market at any time. It has been as high as $10 and as low as 50 cents per pound, and is worth at the East about $3.50, just at present, as nearly as we can find out.

WHAT A BLIND MAN SAW.—San Francisco has been fortunate this week in the opportunity of hearing Rev. W. H. Milburn, the eloquent blind preacher. His lectures on "What a blind man saw in England and in Paris" were most eloquently delivered, and abounded in most thrilling as well as most humorous passages. It is seldom that we have the chance to hear such lectures, and exceedingly seldom that they are properly appreciated as these have been. We advise all our readers to hear the "old man eloquent."

* * *

ELECTRO-SILVERED PLATES.—We have been shown a private letter from the superintendent of the Crescent Mills, Indian Valley, Plumas Co., to the superintendent of the Kanaka mine. One paragraph reads as follows:

"I am pleased to inform you that I have been experimenting with electro-silvered plates for some weeks and the result of our operations with them leads me to anticipate a new era in the art of saving fine quartz-gold, as I am satisfied that much amalgam can be saved by their use, which would otherwise be lost."

* * *

THE first quartz mill for the San Diego mines, which was sent per steamer Oriflamme, is one of Wilson's steam stamp mills. This is to be put up in the Julian District for working on custom ore, and will be in operation within two weeks. It is calculated to crush 25 tons daily.

Ophthalmic Disease.

To chronicle progress is a pleasant duty; and especially pleasant is it to chronicle progress in those arts which directly relate to the relief and prevention of human suffering.

We passed a most agreeable hour the other day at the rooms of Dr. David E. Dudley, an oculist who has recently come among us. We were exceedingly interested in the examination of the Doctor's instruments, models, books and plates, and his explanatory remarks thereon. In this hey-day of quacks, it is refreshing to meet with a medical specialist who does not come under that head. We fully believe that such a thing is possible, despite the prejudice against specialists, which is so general among the members of the medical and surgical profession. It seems to us, by the way, that if any branch of that profession should be set apart as a specialty, it is that which relates to diseases of the eye; not merely because it is in itself a study for a lifetime, but also because it is only by constant and exclusive practice that the delicacy of touch so necessary to one who handles that most delicate of organs can be acquired and retained.

Few persons outside of the medical ranks,—and we fear we might add, few *inside*,—really know what it is to be an oculist. The ophthalmoscope of Helmholtz created a revolution in ophthalmic practice. Before the invention of that instrument, the interior of the eye was a sealed book. The physician was literally looking in the dark, when he attempted to explore it. The sunlight, the aid of which he sought, was shut off in a great measure from the spot where it was most needed, by the necessary interposition of his own head. But now, the little concave mirror of the ophthalmoscope reflects the light from a lamp behind and a little on one side of the patient, directly into the very depths of the organ; displaying and defining every part with all the distinctness of the letters upon a printed page. The observer, who inspects the picture through a small hole in the center of the mirror, can thus acquaint himself with the condition of the interior, as exactly as with that of the exterior, of the eye. By patient study of every little elevation, every little depression, and every peculiarity of color, both in the healthy eye and in the eye under all conditions of disease, he learns to attach to each appearance its meaning; and then, if already well grounded in the principles of general physiology and pathology, he has taken the first step in an oculist's preparatory studies. And the first step only. The reading is yet to be done, which shall enable him to avoid the stumbling-blocks of preceding practitioners; the hand is yet to be trained, which shall coolly and steadily make the critical knife-thrust, where a bungler's awkward slip might "hurl the spirit from its throne of light." Add to this, the ever-changing forms of disease; the complications produced by the presence of other disorders; and especially the fact, just beginning to be recognized, that serious constitutional disease may, much more often than it has been supposed, be prematurely detectable in the more delicate and therefore more susceptible tissues of the eye,—and thereby often furnish a hint for the treatment of the eye itself;—and one may perceive that ophthalmic science is in fact still in its infancy, and hence that the oculist's profession is, as we have said, a lifetime study.

Our readers will not confound the *oculist*, who has gone through these steps, with the *eye-doctor* of the period. The latter belongs to a different school. His system of treatment is different;—so is its result. For example:—the oculist's practiced eye detects in the eye of a patient who presents himself, the deep-seated sign of incipient disorganization, which, if neglected, will soon be irreparable. Not an hour is to be lost; an immediate operation is necessary; he promptly performs it, and the eye is saved. A similar case presents itself to the eye-doctor. Having no notion whatever of the real state of things, and consequently feeling no alarm, he gracefully attitudinizes in front of the patient,—glibly gabbling "glittering generalities" the while,—and gravely proceeds to anoint his eyelids with some perfumed and tinted salve. Meantime the golden moment for action slips by, the mischief is done, the disorganization is complete, and the victim's eyesight is hopelessly lost. This, we may remark, is not wholly a fancy sketch. We, however, also remark, and gladly, that so far as we are aware, nothing of the kind has ever occurred on *this* side the Continent.

Among the advances of late years in ophthalmic surgery, may be mentioned the operation for cataract. This, as most of our readers doubtless know, is an opacity of the crystalline lens; which thus becomes a mechanical obstruction to the passage of light on its way to the retina. Formerly the operation generally performed for its cure was that of "couching,"—which consisted in thrusting a needle into the lens, and depressing it below the line of vision; leaving it there as a foreign body to irritate,—perhaps even to the point of destructive inflammation. This crude and unscientific operation is no longer thought of by the enlightened oculist. The lens is now removed entirely. A very important difference between the two operations is that one almost always failed, while the other, as now performed, almost always succeeds. New instruments now make surgery possible, which, without such aid, would have been entirely out of the question.

Dr. Dudley, although as we have said, a new-comer, is by no means a new practitioner. A New Englander, and educated in the United States, he went early to South America. After a number of years' professional experience in the different cities of that continent, he returned home to perfect himself in the advances made during his absence. A three-years' European tour followed, during which he visited the principal oculists and instrument makers both in England and on the Continent. While in Paris he caused to be made, under his own supervision, the magnificent case of instruments which he showed us; unquestionably the finest that has ever found its way to the Pacific Coast. Every one of its many instruments is exquisitely finished, and the whole is a perfect marvel of compactness and completeness. Many of the improvements were designed by Dr. D. himself. And here we may allude to a most ingenious and important improvement made by him upon what may be considered the chief instrument of all,—the ophthalmoscope. As invented by Helmholtz, it was monocular. A French oculist subsequently made it binocular,—bringing into use both eyes of the observer at once; a great advance, as may readily be seen. The two eye-pieces were made to slide apart by hand, to fit the space between the eyes in different observers. Dr. Dudley, besides making other minor improvements, has put the perfecting touch upon the instrument, by attaching to these eye-pieces a small rod, so arranged, with a right-hand screw upon one end, and a left-hand screw upon the other, that by a single touch of its milled head, both eye-pieces are moved equally and in opposite directions to or from the center. The instrument can thus be adjusted at will with the utmost exactness, and without removing it from the eye.

We must not omit to mention,—although perhaps it belongs to the opticians, rather than the oculist's, part of the subject,—the advance that has been made in the matter of selecting glasses for the various grades of abnormal sight. This has been little better than guess-work; it is now reduced to system. Short-sighted and long-sighted persons, and persons with certain peculiarities of distorted vision, of which perhaps they themselves were never conscious until discovered by a chance comparison of notes with others, have often no conception of the comfort they may derive from properly adapted glasses. And for many reasons it is desirable that the oculist should make the examination and tests of the eyes, and *prescribe* the exact number and form of the glasses; leaving nothing to the optician but the task of preparing them. Dr. D. showed us a complete set of apparatus for the purpose of making such tests.

The manner of Dr. Dudley is marked by affability, by a modesty which itself indicates merit, and withal by a peculiar gentleness which especially fits him for this kind of practice. We take pleasure in introducing him to our readers as a gentleman who, we feel sure, is destined to take a high position.

Patents and Inventions.

A Full List of Patents Issued to Pacific Coast Inventors.

[FROM OFFICIAL REPORTS TO DEWEY & CO., U. S. AND FOREIGN PATENT AGENTS, AND PUBLISHERS OF THE SCIENTIFIC PRESS.]

FOR THE WEEK ENDING MAY 3D.

ORE SEPARATOR.—Thomas Batss, Pinos Altos, New Mexico Territory.

APPARATUS FOR BLASTING LOGS.—Matthew Cooke, Sacramento City, Cal. Antedated April 27, 1870.

HORSESHOE.—George Copeland, Denver, Colorado Territory.

MAINSPRING BARREL ATTACHMENT FOR WATCHES.—Ola L. Eliason, Salt Lake City, Utah Territory.

BOILER FURNACE.—John A. T. Overend, San Francisco. Antedated April 23, 1870.

CARRIAGE WHEEL HUB.—Almond F. Cooper, San Francisco.

PROPELLING WHEEL.—A. C. Lond, San Francisco.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise), at the lowest rates. All patent business for Pacific coast inventors transacted with greater security and in much less time than by any other agency.

* * *

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co's Scientific Press American and Foreign Patent Agency, the following are worthy of mention:

METALLIC PACKING FOR STATIONARY JOINTS.—H. T. Lee, Marysville, Cal.—Mr. Lee has obtained several patents for similar purposes, and this device is, in fact, an improvement on one granted him in June, 1869, and can be made at a less cost. In rendering steam or water tight any stationary joint, a suitable wire, rod, bar or strip of copper or other malleable metal is given an oval or other shape which will produce two thin sharp edges on opposite sides. This is bent so as to fit the outer edge of the surface to be packed, and the edges are united with solder or other brazing materials. A second encircling band is formed of the same material to fit the inner edge of the surface. In order to protect any bolt and to prevent steam from escaping beside a loosely fitting one, rings of the same material are placed around such bolts and between the two bands above spoken of, to which they are soldered. This packing frame having been properly placed on the surface of the steam chest, the cover is placed on it and pressed down firmly by turning the nuts of the bolts. By this pressure the edges of the wires or bands will be compressed, or rather upset, so as to fit each surface tightly, filling any depressions or unevenness in either part. Such a packing can be cheaply made and put upon sale, whereas the ordinary kinds have to be fitted expressly for the particular surface to which they are to be applied.

PRUNING AND GRASPING SHEARS.—C. L. Nichols and F. A. Edler, Folsom, Cal. This device is so constructed that it will not only cut the limb, branch or twig to be severed, but also grasp it, and may be employed not only for pruning, but also for picking or gathering fruit. The blade or cutting jaw is oval in shape, with one sharp edge. The opposite or closing jaw has an equal amount of curve, the two vibrating portions of the shears being united in such a manner that, in closing them, a gap or opening of uniform width will result at every point between the two, and thus the branch or twig will be cut square off, without being forced by a shear motion towards the points. The spring for grasping the severed twig is in the form of a C-spring and is secured to the blade near the back, its sweep bringing it around to the proper position near the cutting point for grasping whatever may be severed by the knife. The operating handles are formed in one of the ordinary styles, but the springs for keeping them separate slide over and past one another in opening and closing the shears, to facilitate which, their ends are curved in opposite directions. The handles have also an ordinary spring catch to keep them closed when not in use.

* * *

CRUCIBLES.—American black lead crucibles, from the manufactory of J. H. Gautier & Co., are to be obtained from E. de Sahla, commission merchant, 310 Davis street, S. F. These have been tested at several places in the city and are very highly spoken of.

Artificial Propagation of Fish.

[CONCLUDED FROM LAST WEEK.]

Artificial Spawning Beds.

While artificial fecundation, says the Report of the Department of Agriculture (of which, with a number of other works,* we have made liberal use), apparently fulfils the chief requisites for the propagation of some fishes, such as the salmonids, there are others for which it cannot be employed with equal advantage. Nature has, in such cases, been assisted by the preparation of places suitable for the deposit of the ova and milt of the fishes which it is desired to propagate, and by the preparation for each of beds which will be instinctively resorted to by them. This practice has been especially employed in France. M. E. Blanchard, professor at the Museum of Naturel History, thus describes an artificial spawning bed, illustrated in Fig. 5:

"For carp, bream, roach, etc., which attach their ova, agglutinated together by a viscid matter, to aquatic plants, stones, or any bodies to which their eggs can be fixed, artificial spawning beds are especially advantageous. Such are easily constructed. A framework of sticks or laths should be made, and to this boughs, furze and aquatic plants should be fastened by cords, so as to form irregular structures. By taking hoops for frameworks a circular form may easily be obtained. The form and size vary according to the character or size of the body of water in which they are to be immersed. They should be held to the bottom by stones and fastened to a stake or post on the bank. It will be readily understood that each bed will be especially serviceable in those streams and canals which are so clear as to be devoid of any natural spawning beds. For the salmonids, which spawn on a gravelly bottom, and whose ova remain free, it is only requisite to cover in certain places the beds of rather shallow and rapid streams, near the bank, with a thick layer of gravel or pebbles, and to prepare slight excavations or furrows, perhaps to raise small heaps of pebbles at the edge of these furrows. By such means trout especially would be attracted, and would spawn in places which they otherwise would not frequent, and where it would be convenient to keep them."

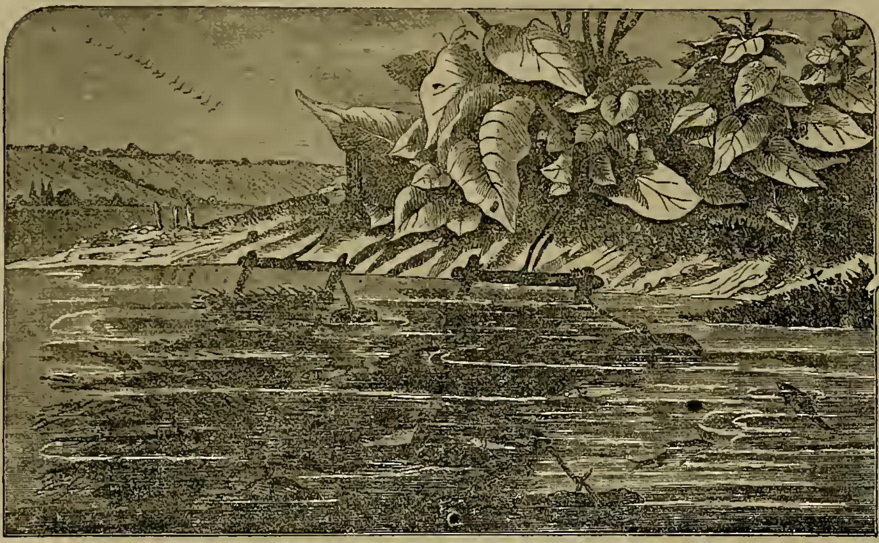

Fig. 5—Artificial Spawning Bed.

Preservation of the Young Fish.

It takes but a few moments for the fecundation of the eggs. By close observation those which are vivified can be distinguished from the barren ones, and in a few days all doubt will be removed. The barren eggs become snow white, while the others show dark specks or lines, which gradually develop into the form of a young fish. The dead eggs must be removed and no sediment of any kind be allowed to collect in the boxes.

When the fish are hatched—which varies, according to the kind of fish and the temperature, from a few days to two months—the water should be raised in the boxes, by damming up the lower ends, and if the box is small, some at least should be put in a stream or pond where they will be protected from all foes. As long as the huge umbilical bladder remains the fish are quiet, and, feeding on its contents, need no other food. After this they must be fed. Twice or thrice a day a little clotted milk, rubbed very fine in water, is a good article. As they grow in size they will take more and larger morsels. Great care must be taken not to give more than is devoured, else the matter on putrifying will sicken and kill the fry.

The food question is important as an economical matter. Raising fish in limited numbers or in the early stages of growth is a simple affair, but to rear large numbers for the table demands close management. Liver chopped fine is very generally given. Beef reduced to small particles is said to be even better, especially if cooked. Fish is sometimes given. Live minnows, small crustacea, and the like, are especially good, and the spawn of the more worthless kinds, as well as the small fry, might easily be obtained in the artificial way with but little trouble. In these fish ponds by introducing aquatic plants, mosses, etc., there will be supplied not only a large amount of food, but also the necessary chemical elements which are being continually exhausted by the fish.

Mr. Norris, in his book on "American Fish Culture," recommends, as a cheap and good way, the breeding of maggots, or the larvæ of the green fly, in refuse meats. A large amount of food can thus be easily obtained, by using any simple device for catching the maggots. He recommends also curds. In regard to the quantity required, each person will soon determine by experiment. Fish, like some other animals, can easily be educated to gorge themselves. Mr. Ainsworth gives about a quart of beef's liver, chopped fine, for each meal for his 1,500 trout, using about two livers weekly. In calculating the expenses of fish culture, Mr. N. gives the following figures, which are of value in this connection:

Pond No. 1—10,000 yearlings	3 qts. curds per day
Pond No. 2—8,000 2-year olds	6 qts. curds per day
Pond No. 3—7,000 3-year olds	12 qts. curds per day
Total..25,000 trout	21 qts.

The Fish Ponds.

The young fish must soon be removed to ponds, of which it is well, if not necessary, to have three. These ponds should be of a shape which will permit the proprietor to watch and have under control all parts, and an oblong form may be recommended. The pond for the youngest fry, say up to the age of 1½ years, should be rather shallow, and may well vary from six inches to two feet in depth. The bottom should be covered with fine gravel. Instead of a pond a trough may be used, if circumstances render it preferable. In a trough twenty-four feet long, two feet wide, and eighteen inches deep, Mr. O. Desh, of New York, has kept 800 to 1,200 trout. A second pond, deeper and larger, can contain older fish, and the third, still larger and deeper, the oldest. These ponds can be connected by troughs, say, for trout, five or six inches deep, two to three feet wide, and twenty or more feet long, with gravel bottom and with screens of painted wire at the outlets. If the bottom of the ponds are covered with stones of rather large size, the fish will seek to spawn in the troughs, and can readily be captured in them at the proper times.

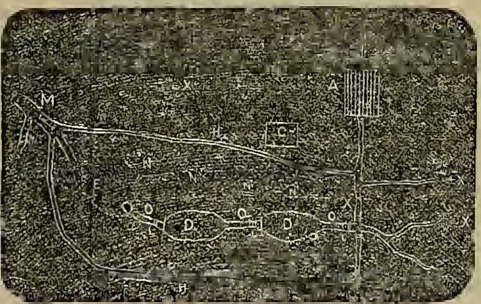

Fig. 6—West Barnstable Fish Establishment.

It is better not to spread out a small amount of water over a large area, but rather to keep it confined in smaller limits, so as to be sure of a current of running water. Some shade should be provided. The objection against trees is, that the leaves, etc., fall into the water and obstruct the screens. Some writers recommend floating boards for this purpose.

According to accounts, Mr. Seth Green, the New York pisciculturist, has some 9,000 trout in a pond seventy-five feet long, twelve feet wide, and five feet deep. Mr. Norris, in his book, bases some calculations on the rate of ten trout to one cubic foot of water. We give these figures merely for their bearing on the determination of the size of a fish pond.

Transportation of Eggs.

Many of the fish establishments sell large quantities of the eggs, which can be transported long distances and used to stock exhausted streams. Various methods have been proposed, which are more or less simple. One plan, that of Mr. Lymen, Commissioner of Massachusetts, appears to be a good one. Take a tin box, the size and shape of a pint measure, collect also a good handful of peat moss, which has been well washed, and lay a stratum of this, wet, on the bottom of the box, covering with a fold of the gauze called "mosquito bar." On this spread a single layer of eggs and cover these with a second fold of the gauze. Then put more moss and another layer of eggs in like manner, and thus continue until the box is full. Put on a cover with a few holes in it, pack the tin in a case of sawdust, and the eggs are good for a month without opening. The eggs must be taken quite early; a good time is as soon as the specks appear on it, as they develop almost as much in the wet moss as in water. By some such apparatus spawn can be transported long distances.

American Establishments.

Of late years, the interest in this subject has largely increased in the United States, and now there are in New England and the Middle States some thirty or forty establishments for the cultivation of fish, principally trout, with a view to profit. One establishment in New York is said to hatch several hundred thousand trout annually, and to have realized as much as $10,000 profit in a single year, the profit arising mainly, however, from the sale of young fish, and of fecundated eggs. We have already taken up so much space that we have no room to describe these, but simply give our readers a diagram showing the West Barnstable (Mass.) establishment.

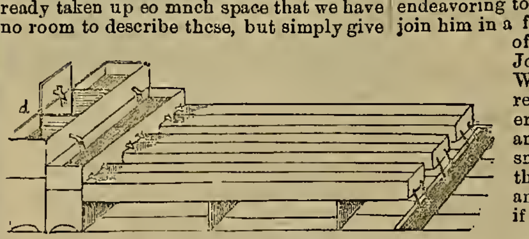

Fig. 7—Hatching Troughs.

The place selected was a swampy piece of ground at the head of a brook, M, of considerable size, fed by half a dozen or more springs, X. The supply of water is about eighteen square inches, and is obtained by sinking wooden tanks in the soft mud, at the points where the springs come to the surface, until the substratum of sand was reached, at an average depth of five feet. The two ponds, D, D, are 40 feet long, 20 feet wide, and from 3 to 4½ feet deep. It is calculated that one will sustain over 2,000 fish weighing about three pounds each, while in the other, three times that number of smaller ones can be kept. The ponds are stoned, and on the bottom are placed flat rocks, so that the trout will not spawn in them, but take to the ways, O, O, O, for this purpose. These ways are plank troughs 50x3½ feet, and filled to the depth of six inches with coarse gravel, over which there are six inches of water flowing with a slight current. The hatching house, A, is 20x12 feet, and is supplied with the amount of water which flows with a moderate pressure through two faucets, one inch in diameter. The hatching troughs, six in number, are of wood lined with slate, and are 16 feet long, 15 inches wide and 8 inches deep. The bottom is covered with an inch of moderately fine gravel, covered with an inch of flowing water. Fig. 7 gives a representation of these hatching boxes. The water flows into the upper trough shown, where it passes through flannel strainers, *d*, thence into the next or distributing trough, and thence through faucets into the hatching troughs. The fish are fed daily with live minnows and shrimps, or, when these cannot be obtained, with chopped liver, the roe of codfish, etc. The establishment was begun in the spring of 1868, and the next year hatched some 60,000 trout and 2,000 salmon ova. In the cut, H, H, H, are drains, and C, E, N, N, N, N, proposed ponds.

Experiments on a Small Scale.

A family supply of fish may be attained at a small expense and little trouble by any one owning a spring of constantly flowing water. A spring supplying an inch of water, which can be collected in a sheltered pond, will suffice for a few specimens and serve to amuse and instruct the amateur; one supplying two inches will sustain a preserve large enough for profit as well as pleasure, although a bigger stream is desirable for experiments on a large scale. Simple contrivances will answer. By placing below the spring a box four feet long and a foot wide, so that the water will flow through it, one can have a hatching box sufficient for the purpose. The upper end is closed by stretching across pieces of flannel, so as to filter the water properly, the lower end is closed by a screen of painted wire, on the bottom is laid gravel, the size of peas, about an inch deep, and for protection against dirt and foes there is placed on top a movable cover. On the gravel lay a layer of eggs, and examine daily, removing the dead ones and any dirt. One will thus have soon a promising young family, which can be removed to a small reservoir, constructed near by, and by enlarging the accommodations as required, any one can soon have quite a fish preserve. For food, one can use refuse scraps of meat, insects, caterpillars, clotted milk, hasty pudding boiled with milk, small minnows, etc. Such a contrivance is within the means of almost any one in the country.

Conclusion.

One or two experiments have been tried in this State in this matter of fish culture. On the Pacheco road, leading out from Oakland, is the "fish ranch" of Mr. M. Disnay, who has made one or two attempts to raise fish. He has, however, been crippled by want of sufficient capital, and freshets have destroyed his young fish once or twice. Still enough has been accomplished to convince him of the profitableness of the thing, and he is, we believe, endeavoring to get one or two persons to join him in a fresh trial. We have heard of an establishment near San José, but have no particulars. We hope that our article may result in raising a more general interest in the matter, for an establishment on a very small scale even will repay the owner in the way of amusement and instruction, if not otherwise.

The last State Legislature passed an act providing for the preservation and restoration of fish in the waters of California, which we publish on page 322 of this issue. Under this act the Governor has appointed Messrs. B. B. Redding, S. R. Throckmorton and J. D. Farwell as Fish Commissioners, to establish and furnish fish-breeding depots upon such waters as may in their judgment be the most proper. We hope they may be well seconded by the people in their efforts; and as they are authorized to distribute ova to persons who will take charge of their culture without expense to the State, a good opportunity is afforded to farmers and others to commence in this pleasant and instructive pursuit. Should the provisions of the act be well carried out, and the people of California appreciate its necessity in time, we shall save many thousands of dollars which older countries have, through neglect of this matter, been obliged to expend. We rejoice in an abundant supply at present, but this should not blind us to the lesson taught by the experience of all other places.

WIESTER & CO.,

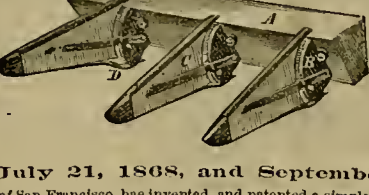
PATENT BROKERS,

No. 314 Bush Street, San Francisco.

PATENTS BOUGHT AND SOLD ON COMMISSION.

For the benefit of those who live at a distance from the city, we give below a brief description of a few of the valuable Patents which we have in our office. It may be well to state here that no Patent is received by us for negotiation until it is first endorsed by reliable experts, to whom each is subjected for acceptance or rejection. We treat all patents alike, recommending only where true merit is found in the invention.

BONNEY'S IMPROVED GRAIN LIFTERS.



Patented July 21, 1868, and September 28, 1868.

Mr. O. BONNEY, Jr., of San Francisco, has invented and patented a simple and practical device for raising fallen down grain, that it may be secured by the knives of the header. Practical farmers and those whose interests are closely allied with them, can testify to the great amount of grain that cannot be gathered by the heading machines in use, and which is annually lost to themselves and the country.

It has been estimated that with the ordinary Harvester one bushel to the acre, on an average, is annually wasted in the State of California. Taking this estimate, which we think is very low, by the use of BONNEY'S IMPROVED GRAIN LIFTERS there would be annually saved to the people of this State more than 700,000 bushels of wheat, 400,000 bushels of barley, and 40,000 bushels of oats. In the above cut three Lifters are represented. A is the header beam, b an iron shank firmly bolted to the beam, to which the finger or lifter, c, is fastened by means of a joint bolt through the iron and the back part of the shank, b. The lifter has an iron point, and is bound with iron, which makes it very durable. They are smooth, affording no chance for grain to hang and burden a train. e is a strip of spring steel, and draws the point of the finger downward. By means of a stop-bolt through the front part of the shank, b, any angle can be given to the Lifter. They can be varied from one inch to two feet from the ground. By elevating the Lifters, they become a complete substitute for what are termed "trinklers," allowing the knives to run close to the ground. The hinge motion of the Lifters prevents them from injuring the header-beam in passing over rough ground. The entire weight of a full set of eight Lifters is forty-eight pounds. One minute is sufficient time to put on or take off each finger.

We claim that this auxiliary for harvesting is much superior to anything else of the kind ever invented, and are prepared to prove the same in the field. A single Lifter will be sent (C. O. D.) at the retail price—five dollars—to any person who may wish to examine them either with a view to buy territory or to purchase Lifters for his own use. If the Lifter is not satisfactory, it can be returned, and we will refund the money, less express charge on the Lifter. We will furnish Lifters at what they cost to manufacture to any person who buys a County or State Right. They can be made at any blacksmith shop, and allow a handsome profit. For Lifters or Rights address WIESTER & CO., 314 Bush Street, San Francisco.

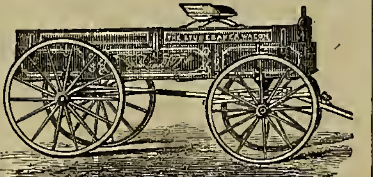
A NEW PAPER FILE AND MUSIC FOLIO.

Two excellent inventions included in one patent. Either can be manufactured at a small cost, and neither has an equal in its line. No more expense for binding music. Each sheet has a complete and durable binding as soon as it is placed in the folio. The California Legislature has endorsed the Paper File by purchasing three hundred and fifty, to take the place of the old style binders. It certainly is the most complete article of the kind ever invented. Whoever buys the right to manufacture and sell this invention will secure a good basis for a profitable business. Only the Territory west of the Rocky Mountains for sale. Parties in the city should call and examine the article. Full particulars furnished on application.

☞We have for sale the Right of A NOVEL AND VALUABLE LITTLE INVENTION for the city of San Francisco. One machine will go with the right. The machine can be attended by a man or small boy, and will yield to the owner a net profit of from two to four dollars per day. The present owner has built up a paying business, but is induced, at the request of friends, to relinquish it and go East. The Right and the Machine will be sold for the small sum of $175. Parties wishing to purchase will call at our office before the fifteenth of this month.

WIESTER & CO.,
314 Bush Street, San Francisco.

The Celebrated Studebaker Wagon,



Manufactured by STUDEBAKER BROS. MANUFACTURING CO., South Bend, Indiana. WAGON DEALERS, there are nine reasons why you should buy the above Wagon:

First.—They are made of the best selected INDIANA TIMBER, thoroughly seasoned under cover.

Second.—They are made by experienced mechanics.

Third.—The lightest running and most durable Wagon in the market.

Fourth.—Their Thimble Skeins never break, while all others do.

Fifth.—Most uniform and best proportioned Wagon in the market; any part of one will fit another, while other makes will not.

Sixth.—The only Wagon in which the Slope Shoulder Spoke is used; hence they have the best Wheel, which is actually the foundation of the Wagon, and should be carefully examined by persons buying.

Seventh.—They are sold only by responsible parties, and every Wagon is warranted to give entire satisfaction.

Eighth.—Because Teamsters will tell you they are the best Wagons, for all purposes, on the road.

Ninth.—Last, but not least, Studebaker Brothers are practical men, attend to their business personally, and do not entrust it entirely to foremen, as is generally the case in large factories; hence the superiority of their work over all others. Sold by

SAPOINE

FRAGRANT SAPOINE FOR THE TEETH.

THE GREAT MEDICAL DISCOVERY!
Dr. J. Walker's California

VINEGAR BITTERS.

More than 500,000 Persons

Bear testimony to their wonderful Curative Effects.

WHAT ARE THEY!

FOR FEMALE COMPLAINTS, whether in young or old, married or single, at the dawn of womanhood or the turn of life, these Tonic Bitters display so decided an influence that a marked improvement is soon perceptible in the health of the patient. PIN TAPE, and other WORMS, lurking in the system of so many thousands, are effectually destroyed and removed. ☞ Send for a Circular. ☜

They are not a vile

FANCY DRINK,

Made of Poor Rum, Whiskey, Proof Spirits, and Refuse Liquor, doctored, spiced, and sweetened to please the taste, called "Tonics," "Appetizers," "Restorers," etc., that lead the tippler on to drunkenness and ruin, but are a true Medicine, made from the native roots and herbs of California, free from all alcoholic stimulants. They are the GREAT BLOOD-PURIFIER and LIFE-GIVING PRINCIPLE, a perfect Renovator and Invigorator of the System, carrying off all poisonous matter, and restoring the blood to a healthy condition. No person can take these Bitters according to directions and remain long unwell.

They are a gentle Purgative as well as a Tonic, possessing, also, the peculiar merit of acting as a powerful agent in relieving Congestion or Inflammation of the Liver, and all the Visceral Organs. In Bilious, Remittent and Intermittent Fevers, these Bitters have no equal. For full directions, read carefully the circular around each bottle, printed in four languages—English, German, French and Spanish.

One Hundred Dollars will be given for an incurable case, provided the bones are not destroyed by mineral poisons or other means, and the vital organs wasted beyond the point of repair.

For Inflammatory and Chronic Rheumatism, and Gout, Dyspepsia or Indigestion, Bilious, Remittent and Intermittent Fevers, Diseases of the Blood, Liver, Kidneys and Bladder, these Bitters have been most successful. Such Diseases are caused by Vitiated Blood, which is generally produced by derangement of the Digestive Organs.

Cleanse the Vitiated Blood whenever you find its impurities bursting through the skin in Pimples, Eruptions or Sores; cleanse it when you find it obstructed and sluggish in the veins; cleanse it when it is foul, and your feelings will tell you when. Keep the Blood pure and the health of the system will follow.

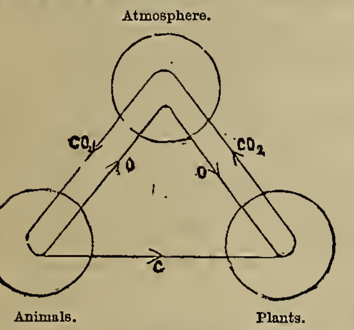
The Law of Circulation.

A most interesting lecture was delivered last Saturday evening by Prof. J. LeConte, of the State University, at the Mechanics' Institute hall. The law of circulation or cyclical movement in Nature, the Professor said, has long been considered by philosophers as the most universal law of material existence. Illustrations of this law show not only its universality, but also that each and every operation is attended with most beneficent results.

The earth, considered as a whole, receives and radiates equal amounts of heat. But in one part, at the equator, it receives more than it radiates, while at the poles it radiates more than it receives. The tendency, then, is to accumulate heat in the one and to diminish its amount in the other; but this tendency is neutralized by currents of air which strive to maintain an equilibrium. The ocean and the land may be compared to a distilling apparatus, the ocean, like the boiler, continually changing water into vapor, which is condensed on the mountains to be returned in streams to the sea. At the poles and on the high mountain regions the snow and ice seek to accumulate; but from the poles the icebergs are floated to warmer climes, and down the mountain sides the glaciers move to feed the rivers; and both are slowly melted, to be evaporated and again carried back whence they came.



The circulation between the organic kingdom and the atmosphere was very neatly illustrated. The atmosphere contains a certain amount of carbonic acid, about one-twenty-five hundredth, besides other matter necessary for the existence of plants (and animals). The rough diagram illustrates this point. The plants draw from the atmosphere carbonic acid (CO_2), which they decompose, returning the oxygen (O), and furnishing the carbon (C) to the animals which feed upon them. These animals take the oxygen from the air and carbon from the plants, and unite these into carbonic acid, which they return to the air to be again decomposed by the plants; and so this circulation continues, without which the supply of food for the plants would soon prove insufficient, and when exhausted, life must cease.

The Professor drew many and varied illustrations from the planetary movements; from history, in the rise and fall of nations and the succession of forms of government; from philosophical systems and opinions. One exception, and one only, he finds to the universality of the rule. Science progresses ever. Here there is no decay and no reaction, but a steady advance to higher civilization and more extended knowledge.

The whole lecture was replete with interest and instruction, was delivered with force and eloquence, and illustrated in a most happy manner. It augurs well for those which are to follow, and which, being free, we hope will be well attended.

◆

Miller and McClellan's Improved Awning.—The patent right for this awning, which we illustrated in our issue of May 7th, for the Pacific States and Territories, has been purchased by Mr. J. M. Stroug, of Snelling, Merced county, Cal., to whom should be addressed any communication with regard to the device.

To Advertisers.

After January 1st, 1870, the latest hour for receiving mining and other advertisements for the M. and S. Press will be during Thursday evening, as our paper will be printed for the interior mails on Friday morning.

A Civil Engineer

Of thirteen years standing and highest Eastern, South American and Pacific coast references, tenders his services at moderate rates. Can present attractive inducements to capitalists. Address W. S. C., Box 1,035, San Francisco. 20v20-1m

☞ Maravilla Cocoa.—*For Breakfast.*—The *Globe* says: "Various importers and manufacturers have attempted to attain a reputation for their prepared Cocoas, but we doubt whether any thorough success has been achieved until Messrs. Taylor Brothers discovered the extraordinary qualities of 'Maravilla' Cocoa. Adapting their perfect system of preparation to this finest of all species of the Theobroma they have produced an article which supersedes every other Cocoa in the market. Entire solubility, a delicate aroma, and a rare concentration of the purest elements of nutrition, distinguish the Maravilla Cocoa above all others. For homœpaths and invalids we could not recommend a more agreeable or valuable beverage." Sold in packets only by all Grocers, of whom also may be had Taylor Brothers Original Homœopathic Cocoa and Soluble Chocolate. Steam Mills—Brick Lane, London. 5v20-1y

Important Invention.—The best drink, not containing alcoholic stimulants, yet answering all the requirements, is that made by Kenyon, Gass & Co., and known as Champagne Mead. It is recommended by the medical fraternity of this city, and should be the exclusive drink of all temperance men. It contains no injurious acids. *

To Miners, Millmen and Metallurgists. Kustel's new work on the Concentration of all kinds of Ores, and the Chlorination Process, for Gold-bearing Sulphurets, Arseniurets, and Gold and Silver Ores generally, is the best and most complete work issued. It contains 120 diagrams, illustrating machinery, etc., which alone are of the greatest value. Price, $7.50, postage paid. Published by Dewey & Co., publishers of the Scientific Press, San Francisco.

Philo B. Fox is requested to report list of subscribers taken for the Scientific Press to date. His agency (for Napa, Sonoma and Mendocino counties) is hereby revoked. His receipts, given previous to this notice, will be acknowledged at this office.

DEWEY & CO., Publishers.

San Francisco, April 28, 1870.

Co-Operative Union Store.—This is becoming one of the most useful Institutions in the city, and the Mechanic and Laboring Man fully appreciate it. They are now enabled to buy their Groceries and Provisions 20 per cent. cheaper than ever before, and the very best articles in the market. The store is located at 115 Sutter street, Lick House Block

To Farmers.—Stevens & Bro's Egg Boxes, holding 30 dozen, supplied free of charge, by John Gray & Co., No. 210 Clay street, San Francisco, to all customers. The eggs are kept cool and free from moisture and mould, are in no danger of being broken, and require no recounting. 20v20-3m

Parties from the country should not fail to see the Portable Gas Light at P. J. Philips & Co., 650 Market street. The cheapest and best light in use. County Rights for sale and Lamps at retail. *

Mason's Bread of Life, for Dyspeptics, Coughs, Colds, Asthma, Catarrh, Hoarseness, Bronchitis and Sore Throat. Price, 25 cents per box. These lozenges are free from all dangerous properties. Compounded and put up by Dr. J. H. Mason, 750 Howard st. 16v20-3m

Photography.—For Cabinet Photographs, or Enameled Cards, of the very best quality, you must go to the NEW YORK GALLERY, Nos. 25 and 27 Third street, San Francisco. Every picture warranted to give satisfaction.

10v18 6m B. F. Howland.

Thomas O'Neil Ornamental Glass Cutter, No. 10 Stevenson street, up stairs. Stained, Ground and Ornamental Cut Glass to order on reasonable terms. 14v20

Microscopes for Scientific Investigation and Educational Purposes. Price list sent free. T. H. McAllister, Optician, 49 Nassau street, New York. 16v20-3m

Drs. Martinache & Smith, Oculists and Aurists, 313 Bush street, between Montgomery and Kearny. Hours for consultation, 12 to 3. 16v20-3m

F. Gruber, Naturalist, No. 626 California street, between Kearny and Dupont, San Francisco. Birds and animals stuffed to order. 13v20-3m

Block Tin and Solder Wire, broom wire, piano covering wire, etc., manufactured by Joshua Gray, 437 Brannan street. 24v19-3m

Surveyors can have their instruments repaired at C. Muller's, 205 Montgomery street. *

And in accordance with law and an order of the Board of Trustees, made on the tenth day of March, 1870, so many shares of each parcel of said stock as may be necessary will be sold at public auction, at the auction rooms of John Middleton & Son, No 310 Montgomery street, San Francisco, California, on Monday, the second day of May, 1870, at the hour of 12 o'clock M. of said day, to pay said delinquent assessment thereon, together with costs of advertising and expenses of sale.

I. N. THORNE, Secretary.

Office, No. 16 Montgomery Block, San Francisco. ar16

Postponement.—The sale of the above stock is hereby postponed until the sixteenth day of May, 1870, at the same hour and place. By order of the Board of Trustees.

ap30 I. N. THORNE, Secretary.

Land Purchasers' Association.—Notice.

At a meeting of the Board of Trustees of the Land Purchasers' Association, held May 3d, 1870, the following resolution was adopted by unanimous vote:

Resolved, That an assessment of ten dollars per share, gold coin, be, and the same is hereby levied, upon each and every share of the capital stock of the Land Purchasers' Association now held by subscribers thereto; being for the monthly installment falling due and payable May 1st, 1870. Said assessment is payable on or before the thirtieth day of May, A. D. 1870, to James F. Crosett, Secretary, at the office of the Association, No. 304 Montgomery street, San Francisco.

Any stock upon which said assessment shall remain unpaid on the thirtieth day of May, A. D. 1870, shall be deemed delinquent, and will be advertised for sale at public auction, and unless payment shall be made before, will be sold at the office of the Secretary, on the twenty-eighth day of June, A. D. 1870, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

J. F. CROSETT, Secretary.

Office, 304 Montgomery street, San Francisco. m7-4w

Mountain City Mining Company.—Location of Mine: Cope District, Elko County, State of Nevada.

Notice is hereby given, that at a meeting of the Board of Trustees of said Company, held on the eighth day of April, 1870, an assessment of fifty cents per share was levied upon the capital stock of said Company, payable immediately, in United States gold coin, to the Secretary, at the office of the Company, No. 408 California street, San Francisco, California

Any stock upon which said assessment shall remain unpaid on the twenty-third day of May, 1870, shall be deemed delinquent, and will be duly advertised for sale at public auction, and unless payment shall be made before, will be sold on Monday, the eleventh day of July, 1870, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Trustees.

T. B. WINGARD, Secretary.

Office, 408 California street, San Francisco. ap16

Miser's Dream Silver Mining Company.

Location of Works: White Pine Mining District, White Pine County, State of Nevada.

Notice is hereby given, that at a meeting of the Board of Trustees of said Company, held on the fourteenth day of April, 1870, an assessment of forty (40) cents per share was levied upon the capital stock of said Company, payable immediately, in United States gold coin, to the Secretary, at the office of the Company, Room No. 36, New Merchants' Exchange, California street, San Francisco, California.

Any stock upon which said assessment shall remain unpaid on Tuesday, the seventeenth day of May, 1870, shall be deemed delinquent, and will be duly advertised for sale at public auction, and unless payment shall be made before, will be sold on Tuesday, the fourteenth day of June, 1870, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

W. F. R. SCHINDLER, Secretary.

Office, Room No. 35, New Merchants' Exchange, California street, San Francisco, California.

Patents on the Pacific Coast.—To those of our friends who desire to keep posted upon inventions upon the Pacific coast we say, subscribe for the Scientific Press, published by Dewey & Co., San Francisco, Cal., at $4 per year. The opening of the railway across the continent has given to all patents a much higher value in that portion of our country known as the Pacific slope, and all interested will find the paper above alluded to a valuable reference.—*Mechanic and Inventor Detroit, Michigan.*

Nevada Land and Mining Company.—Location of Works: Steptoe, Johnson & Latham, Antelope and Cliftou Districts, Elko County, State of Nevada.

Notice is hereby given, that at a meeting of the Board of Trustees of said Company, held on the third day of May, 1870, an assessment of three (3) cents per share was levied upon the capital stock of said Company, payable immediately, in United States gold coin, to the Secretary, at his office, Room 5, No. 302 Montgomery street, San Francisco, California.

Any stock upon which said assessment shall remain unpaid on Tuesday, the seventh day of June, 1870, shall be deemed delinquent, and will be duly advertised for sale at public auction, and unless payment shall be made before, will be sold on Tuesday, the twenty-eighth day of June, 1870, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Trustees.

WM. H. WATSON, Secretary.

Office, Room 5, No. 302 Montgomery street, San Francisco, California. my7

Office of the Placer Gold Mining and Canal Company.—Location of Works: Township No. Six (6), County of Placer, State of California.

D. B. ARROWSMITH, Secretary.

Office, 426 Montgomery street. 1: v20

Silver Vault Tunnel and Mining Company. Location of Works: White Pine Mining District, White Pine County, State of Nevada.

Notice is hereby given, that at a meeting of the Board of Trustees of said Company, held on the third (3d) day of May, A. D. 1870, an assessment of five (5) cents per share was levied upon the capital stock of said Company, payable immediately, in United States gold coin, to the Secretary, at the office of the Company, Room 23 Hayward's Building, No. 419 California street, San Francisco, California.

Any stock upon which said assessment shall remain unpaid on Thursday, the ninth day of June, A. D. 1870, shall be deemed delinquent, and will be duly advertised for sale at public auction, and unless payment shall be made before, will be sold on Wednesday, the twenty-ninth day of June, 1870, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Trustees.

JOSEPH L. KING, Secretary.

Office, Room No. 23 Hayward's Building, No. 419 California street, San Francisco, California. my7

New Advertisements.

By authority of a Special Act of the Legislature of the State of California, approved February 19, 1870, the Trustees of the Mercantile Library Association have the pleasure to announce that a

GRAND GIFT CONCERT

IN AID OF THE

Mercantile Library Association

—WILL BE GIVEN AT THE—

MECHANICS' PAVILION,

SAN FRANCISCO, CAL.,

THURSDAY, SEPTEMBER 1st, 1870,

Under the direction of Distinguished Artists, and embracing selections from the most Favorite Masters. Programme of Concert to be hereafter announced.

Tickets of Admission, $5 Each, Gold Coin.

Each Ticket consists of Five Coupons. The holder of a whole Ticket, or five coupons, will be entitled to admission to the Concert, and to the whole amount of the Gift awarded to it. The holder of each coupon will be entitled to admission to the Concert, and to one-fifth of any gift that may be awarded to such ticket.

To provide funds for this MAGNIFICENT ENTERTAINMENT,

200,000 Tickets will be Sold

At Five Dollars Each, Gold Coin.

TREASURER.......THE BANK OF CALIFORNIA.

During the Entertainment, the sum of

$500,000, U. S. Gold Coin,

Will be returned to the holders of tickets by the distribution, by chance, of the following

GIFTS:

1 Gift of	$100,000,	Gold
1 Gift of	50,000	"
1 Gift of	25,000	"
1 Gift of	20,000	"
1 Gift of	19,000	"
1 Gift of	18,000	"

☞ NOTICE TO MECHANICS.—A premium of $500 will be given for the best model of two Wheels of Glass and Iron, for this distribution. The Trustees reserve the right to reject any and all models.

POST OFFICE BOX, 1089.

WILSON'S

STEAM STAMP MILL.

This mill has now been in use, enduring the severest tests, for the last ten years, during which time it has been introduced into most every mining State and Territory in the Union, and is everywhere received with great and increasing favor, having been in every instance eminently successful, and proved to be the cheapest in first cost, and the most economical in working, and most durable of all stamp mills.

It crushes from **25 to 40 tons** of rock through the ordinary size screens in twenty-four hours, and only requires from two to two and a half cords of wood per day (24 hours). It can be put in operation in a few days after it reaches the mines. The mill is complete when it leaves the shop, and weighs about 6,000 pounds. To be fully appreciated it should be seen in practical operation. Even the most skeptical in improvements of crushing machinery agree to its practicability; and mines that will not pay to work with the ordinary stamp mill can be worked at a profit with the Wilson Steam Stamp Mill. One of these mills can be seen in operation at the Pacific Iron Works, First street. Address,

FURMAN R. WILSON,
San Francisco.

NOTICE.—The improved steam stamp mill that was so complete a failure at Silver City, Nevada, was **NOT** one of the Wilson Mills, but was a **base and fruitless attempt to evade the Wilson Patent,** the Wilson Mill never having failed to give unbounded satisfaction in every particular, so much so that unprincipled parties are using the reputation of the Wilson Mill to foist their own fruitless experiments on the public.

FURMAN R. WILSON.

Railroads and Steamers.

Greatest Discovery Ever Made.

MR. J. W. MAC, while a resident in New Zealand, was so afflicted with the RHEUMATISM, that for years he was completely crippled and unable to attend to business. The symptoms were of the worst type—knees painful and swollen, with sinews contracted; shoulder, arm and hand rendered useless, and accompanied with continued excruciating pain. While in this state of suffering, he got acquainted with a native of the country, who applied to the parts affected a composition spread on coarse canvas, the properties of which were so wonderful that in a short time all the pain left him, the swelling disappeared, his sinews relieved, and he was able to resume his usual avocations. So effectual has been the remedy, that to this day he has enjoyed perfect health, without the slightest return of his former complaint. Knowing the great blessing such a remedy would be to those afflicted with this painful disease, he with great difficulty and expense obtained the secret of preparing the Plaster; and during the many years MR. MAC has applied these Plasters in New Zealand, Tasmania, New South Wales, and this city, their effect has been marvelous, giving to the most painful and long-standing cases sure and certain relief. The most incredulous will be convinced by referring to these persons: B. W. Owens, 405 Front street; F. B. Alderson, Traveling Agent for Dewey & Co., 414 Clay street; James Flynn, 519 Mission street: Michael Gorman, No. 6 Front street; Mrs. W. S Wright—late of Gilmore House—518 Folsom street, now agent at Virginia City; E. Shenley, corner Montgomery and Filbert streets; W. M. McLeod, Depository merican Tract Society, 557 Market street, and a host of others, who all bear testimony to the unparalleled healing powers of J. W. MAC'S (rightly termed Magic) Plasters, for the cure of Rheumatism, Gout, Weak Loins, Tender Feet and Neuralgia. J. W. MAC may be consulted at his office, rooms Nos. 34, 35 and 36, 128 Kearny street, San Francisco, between the hours of 9 to 12 A. M., 2 to 4 P. M. and 7 to 9 P. M.

USE
DR. S. GIRARD SMITH'S
ARAMIRACULAS
— FOR —
RHEUMATISM, GOUT AND NEURALGIA

CURES GUARANTEED.

Has cured Thousands. Has never been known
One bottle will relieve you.

OFFICE, No. 121 POST STREET

Agents Wanted in every City and Town.—Terms Liberal.

Dr. S. Girard Smith, 621 *Kearny street.*—Dear Sir It would be hard for me to say how much I thank you for the benefit your ARAMIRACULAS has conferred on me in curing my RHEUMATISM. I was confined to my bed when I first commenced to take your medicine, and after using ONE BOTTLE I am now able to work as well as before. If you know anything about having that afflictive complaint, you must know how good it is to be cured. I will state to those who may not believe in your medicine, that they can be convinced by referring them to me. Very respectfully, yours,

ENON HARRIS,
Everard's Auction Rooms, 527 Kearny street.

Statement of an old and well-known Physician who has practiced extensively in Europe and America.

We must admit that the many systems of medicine by which we have attempted to heal the human body, and rid it of disease, from the science of ALLOPATHY down to HYDROPATHY, how little they have succeeded, time has abundantly shown by their number of failures. In the cure of RHEUMATISM, GOUT and NEURALGIA, Dr. S. Girard Smith has laid aside the old way and adopted a system, so simple, that I must admit, is so natural and direct, that it recommends itself to all who are suffering with the above diseases. And it challenges and defies all the old methods of treatment. Although I have been educated through a regular course, and graduated in Europe, I must acknowledge the right, and also give due credit for personal benefit received by the new system as practiced by DR. S. GIRARD SMITH, which induces me to bear this testimony to its merits, for the benefit of suffering humanity.

A. M. HOFFMAN, M. D.,
11v20-3m New Orleans.

Ayer's Sarsaparilla,
FOR PURIFYING THE BLOOD.

The reputation this excellent medicine enjoys, is derived from its cures, many of which are truly marvellous. Inveterate cases of Scrofulous disease, where the system seemed saturated with corruption, have been purified and cured by it. Scrofulous affections and disorders, which were aggravated by the scrofulous contamination until they were painfully afflicting, have been radically cured in such great numbers in almost every section of the country, that the public scarcely need to be informed of its virtues or uses.

Scrofulous poison is one of the most destructive enemies of our race. Often, this unseen and unfelt tenant of the organism undermines the constitution, and invites the attack of enfeebling or fatal diseases, without exciting a suspicion of its presence. Again, it seems to breed infection throughout the body, and then, on some favorable occasion, rapidly develop into one or other of its hideous forms, either on the surface or among the vitals. In the latter, tubercles may be suddenly deposited in the lungs or heart, or tumors formed in the liver, or it shows its presence by eruptions on the skin, or foul ulcerations on some part of the body. Hence the occasional use of a bottle of this *Sarsaparilla* is advisable, even when no active symptoms of disease appear. Persons afflicted with the following complaints generally find immediate relief, and, at length, cure, by the use of this *SARSAPARILLA: St. Anthony's Fire, Rose or Erysipelas, Tetter, Salt Rheum, Scald Head, Ringworm, Sore Eyes, Sore Ears,* and other eruptions or visible forms of *Scrofulous* disease. Also in the more concealed forms, as *Dyspepsia, Dropsy, Heart Disease, Fits, Epilepsy, Neuralgia,* and the various *Ulcerous* affections of the muscular and nervous systems.

Syphilis or *Venereal* and *Mercurial Diseases* are cured by it, though a long time is required for subduing these obstinate maladies by any medicine. But long continued use of this medicine will cure the complaint. *Leucorrhœa* or *Whites, Uterine Ulcerations,* and *Female Diseases,* are commonly soon relieved and ultimately cured by its purifying and invigorating effect. Minute Directions for each case are found in our Almanac, supplied gratis. *Rheumatism* and *Gout,* when caused by accumulations of extraneous matters in the blood, yield quickly to it, as also *Liver Complaints, Torpidity, Congestion* or *Inflammation* of the *Liver,* and *Jaundice,* when arising, as they often do, from the rankling poisons in the blood. This *SARSAPARILLA* is a great restorer for the strength and vigor of the system. Those who are *Languid* and *Listless, Despondent, Sleepless,* and troubled with *Nervous Apprehensions* or *Fears,* or any of the affections symptomatic of *Weakness,* will find immediate relief and convincing evidence of its restorative power upon trial.

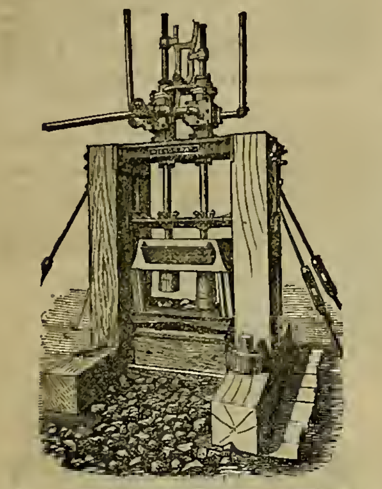
Machinery.

THE WILSON

Patent Steam Stamp Mill.



This extraordinary Mill, now so justly popular in the East, is now offered to the miners of the Pacific Coast. Having been in operation now for about eighteen months, the Company feel confident that the

WILSON STEAM STAMP MILL,

For Durability, Efficiency,

AND ECONOMY OF WORKING,

HAS NO EQUAL.

☞The Wilson Steam Stamp Mill is the only Steam Mill that has had the severe ordeal of practical working, and proved itself eminently successful. It is now in operation in several of the Eastern States and Territories, and gaining an envious popularity. The whole machine is so simple as to be readily understood by the most ordinary minds. In fact, its simplicity is its durability. The expense of crushing rock or cement with this Mill is less than one-half the expense of any other Stamp Mill, and less than one-half the cost. For further particulars inquire of

A. BICKNELE, Agent,
Nevada City, California,

Or of THE WILSON STEAM STAMP MILL CO., 326 Walnut street, Philadelphia, Pa.

Notice.—All persons are hereby warned not to manufacture or use any Steam Stamp Mills that are an infringement on the Wilson Patents, as they will be prosecuted to the utmost rigor of the law.

F. R. WILSON,
20v19-tf Supt. W. P. S. S. M. Co., Philadelphia.

VARNEY'S
PATENT AMALGAMATOR.

These Machines Stand Unrivaled.

For rapidly pulverizing and amalgamating ores, they have no equal. No effort has been, or will be, spared to have them constructed in the most perfect manner, and of the great number now in operation, not one has ever required repairs. The constant and increasing demand for them is sufficient evidence of their merits.

They are constructed so as to apply steam directly into the pulp, or with steam bottoms, as desired.

This Amalgamator Operates as Follows:

The pan being filled, the motion of the muller forces the pulp to the center, where it is drawn down through the aperture and between the grinding surfaces. Thence it is thrown to the periphery into the quicksilver. The curved plates again draw it to the center, where it passes down, and to the circumference as before. Thus it is constantly passing in a regular flow between the grinding surfaces and into the quicksilver, until the ore is reduced to an impalpable powder, and the metal amalgamated.

Setlers made on the same principle excel all others.—They bring the pulp so constantly and perfectly in contact with quicksilver, that the particles are rapidly and completely absorbed.

Mill men are invited to examine these pans and setlers for themselves, at the office, **229** Fremont street,
1v1 San Francisco.

TO MILLMEN.

FOR SALE CHEAP.—A 10-stamp mill complete; engine about 35 horse-power; cylinder 12-inch bore and 30 inch stroke; boiler 16 feet long and 48 inch diameter; weight of stamps complete, 650 pounds. The whole is as good as new; has only been running four months. Will sell either engine or battery separate, and deliver it on the railroad at Auburn if required. For particulars apply to W. NAGEL, 702 Bush street, San Francisco, or to MOUNTAIN CO., Forest Hill, Placer county. 16v20-3m

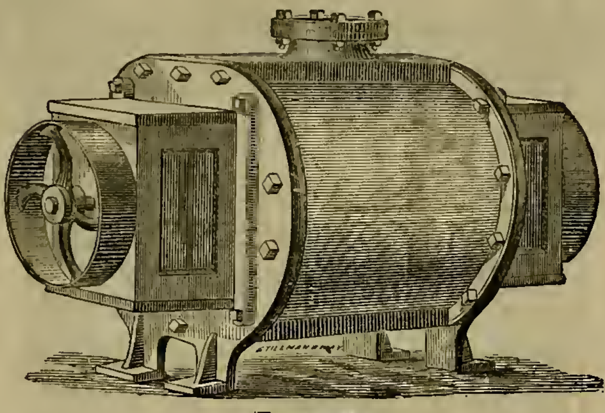
ROOT'S PATENT FORCE BLAST ROTARY BLOWER.

MANUFACTURED BY KEEP & BARGION,

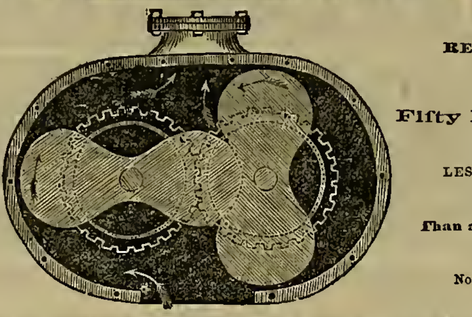
At the Globe Iron Works, Stockton, California.

Awarded the First Premium at the Paris Exposition.



Patented Nov. 1st, 1864; July 24 1866; and Oct. 9, 1866.

ADAPTED FOR Smelting, Foundry, Mining and Steamships.



REQUIRES Fifty Per Cent. LESS POWER Than any Blower Now in use.

One of these Blowers may be seen on exhibition at W. T. Garratt's Brass Foundry, corner of Mission and Fremont streets. They are also in use at the Almaden Quicksilver Mine; Gridley's Foundry, Gold Hill, Nevada; Ætna Iron Works, San Francisco, and many other places.

Caution.—Purchasers will find it to their advantage to apply direct to the Stockton Agency, as certain parties, not authorized to manufacture the Blower, have put in the market machines of inferior construction, which do not answer all the requirements of the genuine article.

Quartz, Saw and Grist Mill Irons, Steam Engines, Horse Powers, High and Low Pressure Steam Engines, Steamboats and Propellers, made at short notice.

For circulars and further information, address

Greatest Discovery Ever Made.

MR. J. W. MAC, while a resident in New Zealand, was so afflicted with the RHEUMATISM, that for years he was completely crippled and unable to attend to business. The symptoms were of the worst type—knees painful and swollen, with sinews contracted; shoulder, arm and hand rendered useless, and accompanied with continued excruciating pain. While in this state of suffering, he got acquainted with a native of the country, who applied to the parts affected a composition spread on coarse canvas, the properties of which were so wonderful that in a short time all the pain left him, the swelling disappeared, his sinews relieved, and he was able to resume his usual avocations. So effectual has been the remedy, that to this day he has enjoyed perfect health, without the slightest return of his former complaint. Knowing the great blessing such a remedy would be to those afflicted with this painful disease, he with great difficulty and expense obtained the secret of preparing the Plaster; and during the many years MR. MAC has applied these Plasters in New Zealand, Tasmania, New South Wales, and this city, their effect has been marvelous, giving to the most painful and long-standing cases sure and certain relief. The most incredulous will be convinced by referring to these persons: B. W. Owens, 405 Front street; F. B. Alderson, Traveling Agent for Dewey & Co., 414 Clay street; James Flynn, 519 Mission street; Michael Gorman, No. 6 Front street; Mrs. W. S Wright—late of Gilmore House—518 Folsom street, now agent at Virginia City; E. Shenley, corner Montgomery and Filbert streets; W. M. McLeod, Depository merican Tract Society, 557 Market street, and a host of others, who all bear testimony to the unparalleled healing powers of J. W. MAC'S (rightly termed Magic) Plasters, for the cure of Rheumatism, Gout, Weak Loins, Tender Feet and Neuralgia. J. W. MAC may be consulted at his office, rooms Nos. 34, 35 and 36, 128 Kearny street, San Francisco, between the hours of 9 to 12 A. M., 2 to 4 P. M. and 7 to 9 P. M.

DR. S. GIRARD SMITH'S
ARAMIRACULAS

— FOR —

RHEUMATISM, GOUT AND NEURALGIA

CURES GUARANTEED.

Has cured Thousands. Has never been known
One bottle will relieve you.

OFFICE, No. 121 POST STREET

Agents Wanted in every City and Town.—Terms Liberal.

Dr. S. Girard Smith, 621 *Kearny street.*—Dear Sir It would be hard for me to say how much I thank you for the benefit your ARAMIRACULAS has conferred on me in curing my RHEUMATISM. I was confined to my bed when I first commenced to take your medicine, and after using ONE BOTTLE I am now able to work as well as before. If you know anything about having that afflictive complaint, you must know how good it is to be cured. I will state to those who may not believe in your medicine, that they can be convinced by referring them to me. Very respectfully, yours,

ENON HARRIS,
Everard's Auction Rooms, 527 Kearny street.

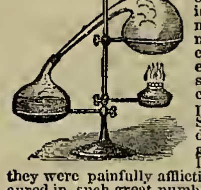
Statement of an old and well-known Physician who has practiced extensively in Europe and America.

We must admit that the many systems of medicine by which we have attempted to heal the human body, and rid it of disease, from the science of ALLOPATHY down to HYDROPATHY, how little they have succeeded, time has abundantly shown by their number of failures. In the cure of RHEUMATISM, GOUT and NEURALGIA, Dr. S. Girard Smith has laid aside the old way and adopted a system, so simple, that I must admit, is so natural and direct, that it recommends itself to all who are suffering with the above diseases. And it challenges and defies all the old methods of treatment. Although I have been educated through a regular course, and graduated in Europe, I must acknowledge the right, and also give due credit for personal benefit received by the new system as practiced by DR. S. GIRARD SMITH, which induces me to bear this testimony to its merits, for the benefit of suffering humanity.

A. M. HOFFMAN, M. D.,
11v20-3m New Orleans.

Ayer's Sarsaparilla,

FOR PURIFYING THE BLOOD.



The reputation this excellent medicine enjoys, is derived from its cures, many of which are truly marvellous. Inveterate cases of Scrofulous disease, where the system seemed saturated with corruption, have been purified and cured by it. Scrofulous affections and disorders, which were aggravated by the scrofulous contamination until they were painfully afflicting, have been radically cured in such great numbers in almost every section of the country, that the public scarcely need to be informed of its virtues or uses.

Scrofulous poison is one of the most destructive enemies of our race. Often, this unseen and unfelt tenant of the organism undermines the constitution, and invites the attack of enfeebling or fatal diseases, without exciting a suspicion of its presence. Again, it seems to breed infection throughout the body, and then, on some favorable occasion, rapidly develop into one or other of its hideous forms, either on the surface or among the vitals. In the latter, tubercles may be suddenly deposited in the lungs or heart, or tumors formed in the liver, or it shows its presence by eruptions on the skin, or foul ulcerations on some part of the body. Hence the occasional use of a bottle of this *Sarsaparilla* is advisable, even when no active symptoms of disease appear. Persons afflicted with the following complaints generally find immediate relief, and, at length, cure, by the use of this ***SARSAPARILLA: St. Anthony's Fire, Rose or Erysipelas, Tetter, Salt Rheum, Scald Head, Ringworm, Sore Eyes, Sore Ears,*** and other eruptions or visible forms of ***Scrofulous*** disease. Also in the more concealed forms, as ***Dyspepsia, Dropsy, Heart Disease, Fits, Epilepsy, Neuralgia,*** and the various ***Ulcerous*** affections of the muscular and nervous systems.

Syphilis or ***Venereal*** and ***Mercurial Diseases*** are cured by it, though a long time is required for subduing these obstinate maladies by any medicine. But long continued use of this medicine will cure the complaint. ***Leucorrhœa*** or ***Whites, Uterine Ulcerations,*** and ***Female Diseases,*** are commonly soon relieved and ultimately cured by its purifying and invigorating effect. Minute Directions for each case are found in our Almanac, supplied gratis. ***Rheumatism*** and ***Gout,*** when caused by accumulations of extraneous matters in the blood, yield quickly to it, as also ***Liver Complaints, Torpidity, Congestion*** or ***Inflammation*** of the ***Liver,*** and ***Jaundice,*** when arising, as they often do, from the rankling poisons in the blood. This ***SARSAPARILLA*** is a great restorer for the strength and vigor of the system. Those who are ***Languid*** and ***Listless, Despondent, Sleepless,*** and troubled with ***Nervous Apprehensions*** or ***Fears,*** or any of the affections symptomatic of ***Weakness,*** will find immediate relief and convincing evidence of its restorative power upon trial.

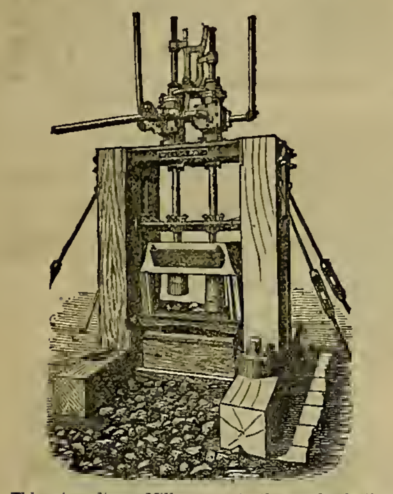
Machinery.

THE WILSON

Patent Steam Stamp Mill.



This extraordinary Mill, now so justly popular in the East, is now offered to the miners of the Pacific Coast. Having been in operation now for about eighteen months, the Company feel confident that the

WILSON STEAM STAMP MILL,

For Durability, Efficiency,

AND ECONOMY OF WORKING,

HAS NO EQUAL.

The Wilson Steam Stamp Mill is the only Steam Mill that has had the severe ordeal of practical working, and proved itself eminently successful. It is now in operation in several of the Eastern States and Territories, and gaining an envious popularity. The whole machine is so simple as to be readily understood by the most ordinary minds. In fact, its simplicity is its durability. The expense of crushing rock or cement with this Mill is less than one-half the expense of any other Stamp Mill, and less than one-half the cost. For further particulars inquire of

A. BICKNELE, Agent,
Nevada City, California,

Or of THE WILSON STEAM STAMP MILL CO., 326 Walnut street, Philadelphia, Pa.

Notice.—All persons are hereby warned not to manufacture or use any Steam Stamp Mills that are an infringement on the Wilson Patents, as they will be prosecuted to the utmost rigor of the law.

F. R. WILSON,
20v19-tf Supt. W. P. S. S. M. Co., Philadelphia.

VARNEY'S PATENT AMALGAMATOR,

These Machines Stand Unrivaled.

For rapidly pulverizing and amalgamating ores, they have no equal. No effort has been, or will be, spared to have them constructed in the most perfect manner, and of the great number now in operation, not one has ever required repairs. The constant and increasing demand for them is sufficient evidence of their merits.

They are constructed so as to apply steam directly into the pulp, or with steam bottoms, as desired.

This Amalgamator Operates as Follows:

The pan being filled, the motion of the muller forces the pulp to the center, where it is drawn down through the aperture and between the grinding surfaces. Thence it is thrown to the periphery into the quicksilver. The curved plates again draw it to the center, where it passes down, and to the circumference as before. Thus it is constantly passing in a regular flow between the grinding surfaces and into the quicksilver, until the ore is reduced to an impalpable powder, and the metal amalgamated.

Setlers made on the same principle excel all others.—They bring the pulp so constantly and perfectly in contact with quicksilver, that the particles are rapidly and completely absorbed.

Mill men are invited to examine these pans and setlers for themselves, at the office, **220** Fremont street,
1v1 San Francisco.

TO MILLMEN.

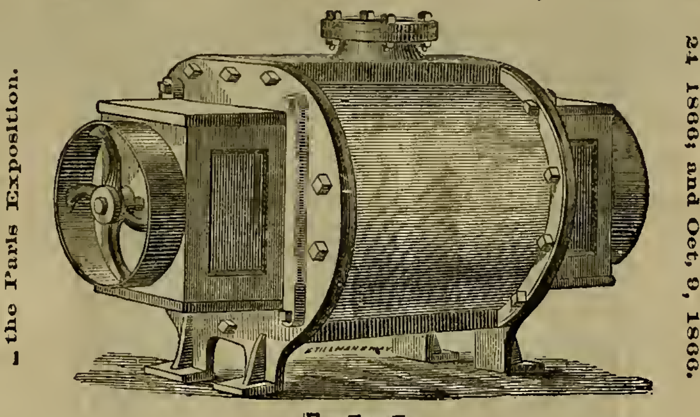
FOR SALE CHEAP.—A 10-stamp mill complete; engine about 35 horse-power; cylinder 12-inch bore and 30 inch stroke; boiler 16 feet long and 48 inch diameter; weight of stamps complete, 650 pounds. The whole is as good as new; has only been running four months. Will sell either engine or battery separate, and deliver it on the railroad at Auburn if required. For particulars apply to W. NAGEL, 702 Bush street, San Francisco, or to MOUNTAIN CO., Forest Hill, Placer county. 16v20-3m

ROOT'S PATENT FORCE BLAST ROTARY BLOWER.

MANUFACTURED BY KEEP & BARGION,

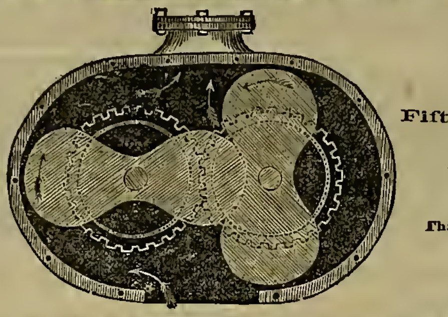
At the Globe Iron Works, Stockton, California.

Awarded the First Premium at the Paris Exposition.



Patented Nov. 1st, 1864; July 24 1866; and Oct. 9, 1866.

ADAPTED FOR Smelting, Foundry, Mining and Steamships.



REQUIRES Fifty Per Cent. LESS POWER **Than any Blower** Now in use.

One of these Blowers may be seen on exhibition at W. T. Garratt's Brass Foundry, corner of Mission and Fremont streets. They are also in use at the Almaden Quicksilver Mine; Gridley's Foundry, Gold Hill, Nevada; Ætna Iron Works, San Francisco, and many other places.

Caution.—Purchasers will find it to their advantage to apply direct to the Stockton Agency, as certain parties, not authorized to manufacture the Blower, have put in the market machines of inferior construction, which do not answer all the requirements of the genuine article.

Quartz, Saw and Grist Mill Irons, Steam Engines, Horse Powers, High and Low Pressure Steam Engines, Steamboats and Propellers, made at short notice.

For circulars and further information, address

Important to Assayers.

Crucibles.

The Patent Plumbago Crucible Co.

Manufacturers of all kinds of
Melting Pots, Portable Furnaces,
CRUCIBLES, and other fire-standing Goods,
Battersea Works, London.

THE MORGAN PATENT CRUCIBLES have uniform quality, never crack, withstand the greatest heat without danger; heats more rapidly than any other; change of temperature has no effect on them; stand on the average forty to fifty pourings.

CERTIFICATES:

United States Branch Mint, San Francisco, Cal., March 12, 1869—Messrs. A. S. Hallidie & Co., Agents Morgan Crucible:—I have carefully tested the Morgan Patent Plumbago Crucibles purchased from you for the U. S. B. Mint, and cheerfully certify to their superiority and economy over all other Crucibles used by and under me. They are fully what you represent them, and I shall continue to use them in preference to any other. J. M. ECKFELDT,
Melter and Refiner, U. S. B. Mint.

Eagle Brass Foundry, 206 Fremont street, San Francisco 12th March, 1869—Messrs. A. S. Hallidie & Co., 519 Front street—Gentlemen:—We have used and tested the Morgan Patent Plumbago Crucible, for which you are agents, and pronounce them superior to and cheaper than any Crucible used by us heretofore. GREENBERG & MOORE.

Messrs. A. S. Hallidie & Co:—We have thoroughly and severely tested in every way the Morgan Patent Plumbago Crucible obtained by us from you, and find them superior to any we have yet tried, although we have used every pot obtainable in this market, we have none equal to the above, and concede your claims for them. We think they will average 45 pourings of brass.
GALLAGHER, WEED & CO.,
California Brass Works, 125 Front street, San Francisco.

Assay Office of H. Harris, Silver City, Nevada, April 24, 1869—Messrs A. S Hallidie & Co.—Gents.:—I received from you three Crucibles of the Morgan make, which I have used since their arrival, and tested by constant use. Since 1847, when in the New Orleans Mint, I have always preferred the Crucible of Dixon's make over Adus, Gautier, and Taunton, Mass. Yours I find to be not alone of more finished make, but to stand double or treble the work of Dixon's Crucibles. The No. 12—the smallest sent—has stood so far 32 meltings, and is as good and sound as when received. Your Crucibles do not scale off like others; and as they are forty per cent. cheaper, I do not see why they should not be preferred by all assayers on account of durability and cheapness. Yours respectfully, H. HARRIS.

On hand and for sale by the Agents,

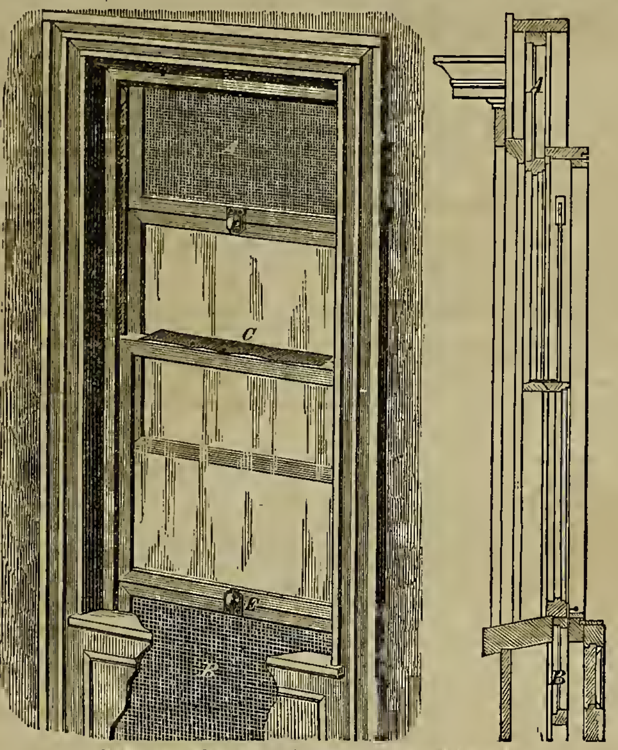
VOLUME XX.
Number 21.

Screen Attachment for Windows.

Reader, have you an antipathy for flies? Have you had your slumbers disturbed by the attacks of the persevering musquito, until you have lost all peace of mind and body? If you have had the experience of the majority in this respect, you will be interested in the device we illustrate to-day, which is intended to exclude insects from the interior of houses, while it permits the windows to be opened in warm weather for the entrance of the refreshing breeze.



IMPROVED SCREEN ATTACHMENT FOR WINDOWS.

The device is simple and can be easily understood from the cuts. A screen of wire, A, B, is attached to each sash and moves with it when raised or lowered. These screens work in box-heads formed above and below the windows, so that when the sashes are closed, they are out of sight, while they fill the open spaces when the window is open. To the top of the lower sash is fastened a guard or strip of elastic material, C, which reaches to the glass of the upper sash, thus preventing the entrance of the invading insect when the window is open.

By this arrangement, which is so constructed as to keep out the wind and rain when necessary, there is no danger of insects being able to enter the house through any carelessness or neglect in placing the screens, as these are always in place. And, moreover, they can be easily detached by means of a metallic strap, E, when it may be desired. The whole is very neatly constructed, and, while comparatively inexpensive, can be easily fitted up so as to present a very neat appearance.

The first cut gives a perspective view of the window with the upper sash lowered and the lower raised a little, so as to admit of the room being thoroughly ventilated. The second cut gives a section through the window showing the manner of construction. This, it will be seen, is very simple, and does not differ materially, except in having the box-heads above and below, from the common construction.

This arrangement will be appreciated by housekeepers, who are continually warring on the invading fly, and by all who live where troublesome winged insects abound. Being so simple there is no danger to be apprehended of its getting out of repair, while, as before remarked, it has the advantage of being always in place. A patent has been granted through the SCIENTIFIC PRESS agency to the inventors, Messrs. Hoagland, Reed & Newsom, of Brooklyn, Cal. Application for further information may be made to Messrs. Hoagland & Newsom, architects southwest corner of Sacramento and Kearny streets, San Francisco.

* * *

THE ACADEMY OF SCIENCES.—At the regular meeting this week a valuable collection of shells and antiquities was presented by Mr. A. Garrett, of Tahiti. A specimen of meteoric iron, from Mr. J. A. Lapham, of Wisconsin, was also received. A field meeting was ordered for to-day (Saturday), to examine the so-called Indian mounds at the Potrero. Dr. Cooper delivered an interesting lecture on the caves of California.

* * *

THE Butte *Record* states that, after an absence of nearly a year, the Locher steam plow made its appearance in town again on Thursday of last week. Their new machine is about ready to be put together, and the original one is to be dismounted, and the engine placed upon the new one.

The Endless or Band Sawing Machine.

Many years have elapsed since band or ribbon saws were first applied for the purpose of cutting curvilinear and irregular work. The advantages of such have long been seen. They are exceedingly simple, when considered with reference to the variety of work they perform. There is no jar or vibration; their action is continuous; the saw can be made thinner than those of reciprocating machines, and hence can be worked without making too wide a kerf or slit; the cut is at right angles with the face, and the dust is all carried down through the kerf, leaving the top surface clean, so that the operator can always follow the line.

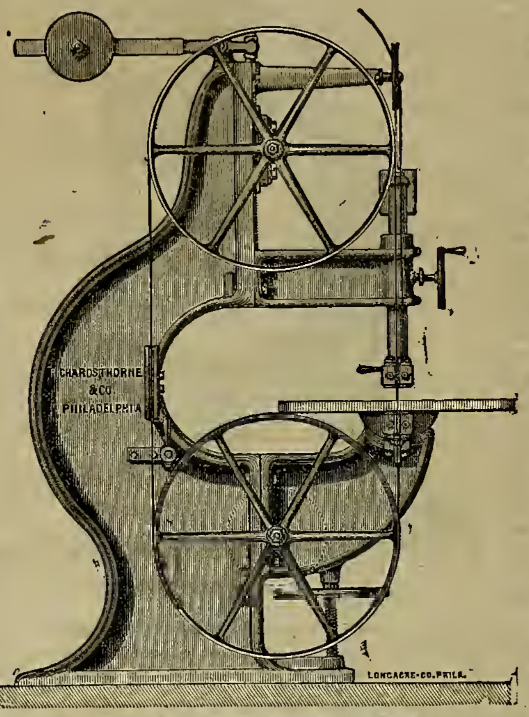


FIG. 1—NO. 4 BAND SAWING MACHINE.

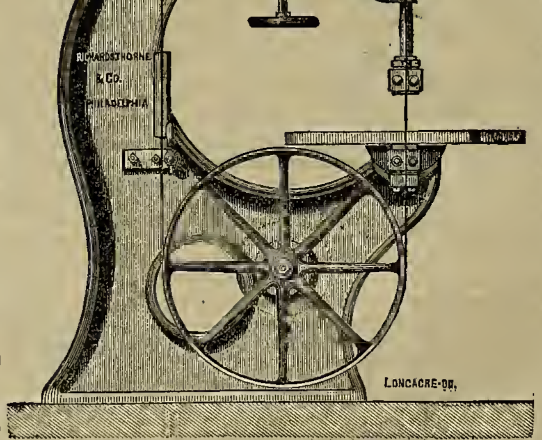

FIG. 2—NO. 3 BAND SAWING MACHINE.

The difficulty experienced in making the saw durable for a long time prevented any general use of these machines, until M. Perin, of Paris, if we are not mistaken, discovered a method of manufacturing and tempering by which the risk of breakage was lessened; and since then such advances have been made that, with proper care and attention on the part of the workman, there is but little danger of breakage, which results, generally, either from neglect or from a poor construction of the machine; not from cutting or from bending over the wheels.

We illustrate three band sawing machines designed by Richards, Thorne & Co., of Philadelphia, Pa., on which patents for improvements are pending. These machines are solidly constructed, the frames being cast in one piece and with enough metal in their cross section to withstand the strain of the saw and prevent vibration. The saws are supported by guides, with cylindrical back supports of hardened steel and adjustable lateral plates. This back support can be rotated so as to bring any part of its periphery in contact with the saw blade, and has a sufficient diameter to present about one hundred independent wearing surfaces. The lateral guides are also of hardened steel. The shafts are of steel, and run in long self-oiling brass bearings.

The No. 4 machine (Fig. 1) is of large size, and is adapted for ship-work and car-building and for large pattern shops. To regulate the tension of the saw-blade and provide for expansion and contraction—in earlier machines so fruitful a source of breakage—there is a weight and lever. The table is planed true and pivoted for bevel sawing, and can be set at various heights from the floor to suit the convenience of the operator or the depth of the stuff to be sawn. This is an important feature when both deep and thin sawing is done on the same machine, as the top of the stuff can thus be kept at the same level. Another important point is, that a compensating arrangement can be applied to the driving belt and the table continually adjusted to suit the depth of the work and prevent unnecessary strain on the driving shaft when light work is being done; this being effected by means of the hand-wheel seen in the cut; or two different belts, for deep or for thin sawing, can be used, the change from one to the other being conveniently performed by raising or lowering the bracket.

The No. 3 or medium-sized hand-sawing machine (Fig. 2) is adapted both to light and heavy work, and is so arranged that the saws can be readily changed to meet the requirements of jobbing. In the absence of other machines, it can be used for cross-cutting, slitting, and cutting out stuff.

No. 2 (Fig. 3) is a still smaller size, adapted for small shops where a cheap machine is wanted. Both of these are fitted with an elastic straining device, and all have a safety shield to protect the operator, should the saw happen to break.

For sawing metal the machines require no change, except the addition of proper appliances to regulate the speed of the saw. Each has a belt-shifter and a full set of wrenches, and is furnished with one saw and an apparatus for joining the blades. They are provided with improvements which are from time to time found to be of value, and the manufacturers claim great advantages for them. They are made by Messrs. Richards, Tborne & Co., Columbia avenue and Fifth street, Philadelphia, to whom any communications as to their operation and application may be addressed.

Morning Star Ore.

Editors Press:—As some misapprehension appears to exist as to the value of this ore, in consequence of my analysis, published in your issue of December 18th last, I beg to explain that as this analysis was made more for scientific than commercial purposes, no particular care was observed in taking the hand specimens, from which the analysis was made, from the *small* dump at the mouth of the tunnel. On testing a portion of the yellow pyritous ore, which constitutes the bulk of the *principal* dump at the hoisting works, I found a very marked difference in my results—the latter showing but $3.14 silver, traces of gold, and traces of copper; being, in fact, nothing but ordinary mundic. W. T. Rickard, F. C. S.

Leviathan mine, May 10th, 1870.

* * *

To Strengthen Fruit Trees.—Fruit and ornamental trees will sometimes so form their crotches as to split down under a heavy load of fruit or violent wind. The evil can be obviated in arching or cross grafting. Take a vigorous shoot in spring, and insert one end under the bark of the main stem and the other under that of the opposite branch. Tie the branches firmly together, to prevent slipping apart in windy weather. Or, instead of taking a separate scion, a growing sprout may sometimes be found near the place needing to be strengthened, and by cutting off the top it may be inserted under the bark of the opposite limb. These branches may be put in every few years, as the tree needs them. Such "Siamesed" trees are quite interesting objects to look at.

Communications.

Letter from Austin.

[Written for the Scientific Press.]

Editors Press:—I left Battle Mountain at 3 p. m. for Austin, taking the stage of J. P. Cope & Co. This company has a fine stock of horses, 40 in number, and makes the trip of 96 miles in less than eighteen hours. There are five stations on the way, the road is level, and the company shows every disposition to render the trip as comfortable as possible for the traveler and to give every accommodation to the public.

Austin and Vicinity.

We arrived in this place about half-past eight o'clock in the morning. Austin was first settled in 1863, at the discovery of the silver mines. It grew very rapidly at first, and then the population decreased, and now there are some 3,000 inhabitants. I see here fine and expensive mills and hoisting works, but am sorry to say that many are at present idle. There is a city hall, two brick churches and a daily newspaper, the Reese River *Reveille*, which, under the able editorship of Mr. O. L. C. Fairchild, is one of the best and liveliest of the interior papers. I understand that there is a prospect of having a branch road here from the C. P. R. R. This would be a great advantage to the place, and would enable the miners to obtain wood and other materials at so much lower prices that it would inspire new life into operations here, and enable mines to be worked at a profit which now must lie idle.

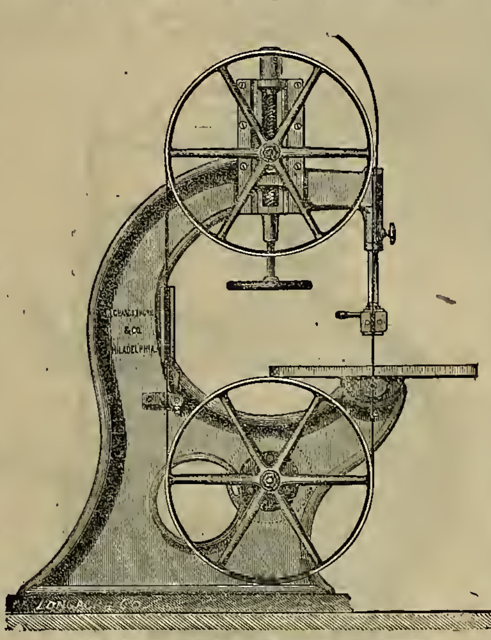

FIG. 3—NO. 2 BAND SAWING MACHINE.

I was suprised at the number of "chloriders," as they are called, who are hunting over the hills in search of new lodes and sorting rock, on shares, from dumps of mines which have ceased being worked. Some of these thus get rock, which they have treated at the Manhattan mill, and make money therefrom. I see in many of the dumps ore which will yield from $40 up to the hundreds per ton, but which, in the early days, was thrown out with the waste rock. There are many mines in this district with ore holding from $20 to $60 per ton, which are idle, waiting for new and cheaper process of reduction.

The Manhattan Company.

I visited the mill of the Manhattan company of New York and was conducted through the works by the general manager and superintendent, Mr. A. A. Curtis, a most energetic and capable gentleman. The mill is at present standing still, while being remodeled for the introduction of the Stetefeldt furnace, which is being built under the supervision of Mr. Edward V. Standish, whom you may know as a brother of the inventor of the Standish steam plow. The furnace will, it is thought, be in operation about the tenth of June, when, no doubt, your readers will have full accounts of its working. This company has bought the exclusive right for the district. Some miners are apprehensive that they will take advantage of this to keep up the price of working ores; but I am given to understand that the price will be reduced as much as possible. The furnace will be a great blessing to the place, and will do much to develop the mines, if properly managed.

Lander Hill.

To give a full description of the formations on this hill would fill a good-sized book, and, moreover, so much has already been published about the place that I need speak but briefly at the present time. The country rock, as you know, is granite, and the veins, which at first produced large amounts of the chloride of silver, at lower depths yield sulphurets, which render necessary a preliminary roasting in their treatment; and it is this roasting which makes the operation so expensive.

Hence, many mines are now idle, and the times have been very dull; but with the successful operation of the Stetefeldt furnace and with other improved processes which are bound to come, I look forward to a general brightening at no distant time and to renewed prosperity in the district. I send you a few notes relating to the present condition of some of the principal mines.

Manhattan, Pacific, Plymouth, Toyabe.

The Manhattan company, under its energetic management, have put in a new pump and engine lately, and are making other improvements. They will soon have about a hundred men at work, and evidently mean business.

The Pacific S. M. Co., of London, which has lately invested here, is at work on its mine west of the Manhattan, and is down 600 feet. They started in last December, and are pushing work under the able superintendence of Mr. James Brown.

Mr. D. F. McKim and others have lately struck a fine body of ore, yielding from $100 to $300 per ton, in the Plymouth shaft, to the west of the Pacific, having leased the mine from a New York company. They are stowing the ore away in the drifts (being fearful of losing it, should they bring it to the surface) until the furnace and mill shall get to work.

The main shaft of the Toyabe S. M. Co., of Philadelphia, is down 330 feet. I went through this mine in company with Mr. C. W. Calvert, the superintendent and part owner. Passing about 25 feet west, where the Lizzie Calvert ledge was struck, I found the vein 27 inches wide; but they have run a drift some 135 feet along the lode, when it widens out to four feet. Three different assays of the ore were returned as $127, $788 and $1,003; only two men are employed, however, at present, night and day.

Waverly—U. P. Tunnel.

On the Waverly ledge, owned by Geo. W. Henry & Co., they are 100 feet down and in ore assaying from $400 to $600 per ton. They are hoisting by means of a windlass.

The Union Pacific Tunnel Co., of New York, have their tunnel about one mile from town, on the grade going up the cañon. This was surveyed to run in under Lander hill, having a direction of N. 71° E., and to cut the ledges nearly at right angles. At the mouth of the tunnel is an open cut, 150 feet long and 44 feet wide, and having a face 22 feet high at the tunnel. This latter is 9 feet wide and 7 feet high, and is to have a double track. In the bottom they will have a drain two feet square for the water. They are now in some 80 feet, and employ daily nine men in three shifts. The greatest depth below the surface will be 1,500 feet. At a distance of 350 feet from the mouth they expect to cut the Old Pony ledge, and after this many others, among them the Manhatten, and Lane & Fuller. They talk of erecting at the entrance a wall 4 feet thick and 22 feet high, and a frame building, 44x50 feet, for ore house, blacksmith shop and office. They have bought 58 acres of land near the tunnel. The water they intend to carry around the side of the hill and use for irrigation purposes. Their work is attracting much notice, and, if successfully prosecuted, will bring about great results. The officers are: B. L. Franke, President, J. W. Naughin, Secretary, and T. J. Harlem, General Agent at the mime.

W. H. M.

* * *

The Mont Cenis tunnel will be finished this year. Ten thousand five hundred and ninety-eight metres have been excavated, leaving only 1,621 metres (less than one mile) to be done. Meanwhile such improvements have been made in engines and cars for very steep grades that the railway *over* the mountain may prove to be quite as economical, and quite as safe and comfortable, as the railway *through it.*—*Exchange.*

Letter from Cerro Gordo.

[Written for the Scientific Press.]

Editors Press:—Having seen in your valuable journal that you have heretofore re-published some of my communications, I take the liberty to direct a letter to you in person, which you may either publish or consign to the waste basket, as you may think proper. Being a constant reader of your paper (whenever I am fortunate enough to obtain a copy), I thought you would like to know what is transpiring in this section of our State in mining matters.

The Situation of the Camp.

Cerro Gordo, a mining camp of some four years of age, is situated in the southern end of the Inyo range of mountains, about 40 miles southeast of Independence, the county seat of Inyo county, and on the eastern side of Big Owens Lake, and eight miles distant from the same. About two years ago, Messrs. M. W. Belsbaw & Co. obtained a charter for and completed a toll road from the eastern shore of Big Owens Lake up the mountain to this place. Since that time the camp has been improving.

Smelting Works.—Water.

Upon the completion of the said road, Messrs. M. W. Belshaw & Co. erected roasting and blast furnaces, which have proved a perfect success in working the rebellious silver ores for which the Owens River country has been noted. B. & Co. are shipping crude lead bullion at every opportunity by mule teams to Los Angeles for San Francisco, and have on hand at present 1,200 bars. The most serious drawback heretofore to this camp was a scarcity of water, but that difficulty has been removed by the energy and enterprise of a number of the citizens of Cerro Gordo, Lone Pine and Independence, in laying a pipe to a spring four miles distant; and as I write, water is running to waste in the streets of Cerro Gordo, the supply having gained on the consumption 4,000 gallons in 48 hours. Knowing there are a number of gentlemen in San Francisco partially attracted by the richness of our mines, I think this will be a fact worth knowing.

Ores of galena are now selling at $15 per ton on the dump, silver ores at 20 per cent. discount of assay, less $60 per ton for working by the smelting process. Assays of the ores vary from 200 ozs. to 600 ozs. per ton; ores yielding less than the first named amount being retained upon the dump of the different mines as a second class.

The Mines.

Among the most noted of the present *partially* developed mines are, first, the Ignacio, being the oldest, and one of the richest, having been explored to the depth of 100 feet; second, the Belmont, now at the depth of 150 feet, with a tunnel coming to the surface at that depth, contains a vein of good paying metal of about four feet in thickness; third, the Wittekind mine, discovered about one year ago, has now a shaft of 90 feet in depth, with side drifts of 20, 60 and 90 feet in length, at the respective depths of 20, 60 and 90 feet, having yielded pay ore from the surface. Cumberland comes next in date of discovery, but yields richer ores than any of the preceding veins, although not quite as much in quantity. The Crowning Glory and Osceola are two new discoveries, showing veins well defined at 50 feet in depth, and from four to six feet thickness of pure metal—*i. e.*, free of barren quartz.

The most noted of the galena mines are named the Union, Santa Maria, Defiance, Frnnt, Freiberg, Guaymas, Buckingbam, and several of lesser developements, The Freiberg, Santa Maria and Union are cut by tunnel 500 feet in length. Large amounts of ore are being extracted daily from all of the above galena mines, except the Guaymas and Buckingham.

If such jottings as the above are in any manner interesting to you or your readers I shall be happy at times to devote a few moments in the jotting. Crowquill.

Cerro Gordo, Inyo Co., April 27, 1870.

* * *

An Elevated Railway.—They have an "elevated railway," as they call it, in New York city; but the most elevated railway in the world is that which runs from Arequipa to Cuscn, in Peru. Its highest point is 15,096 feet, or about three miles, above the level of the sea. At this altitude, the air is only half as dense as at the sea level, the average height of the barometer being only 14 inches. According to Mr. W. T. Brigbam (in *Old and New* for March), the highest pass on the great Pacific Railroad is 12,400 feet high.—*Journal of Chemistry.*

Mechanical Progress.

Cheseborough's Elevated Railway.

The N. Y. *Engineering and Mining Journal* describes a new system of locomotion for elevated roads. "The track consists of a series of inclined planes suspended by cables; the cars run down the inclines by their own gravity, and, by elevating platforms at the foot of every incline, they are raised to the head of the next. The elevating platforms are intended to be worked by compressed air, which is to lift a piston working in vertical cylinders; and to the piston-rod, the platforms, kept in place by guides, are to be attached directly. The compressed air is furnished by means of a stationary engine, air-pumps and receivers located at the end of the route. From the reservoirs a four-inch pipe is to run all along the road, and by the necessary smaller pipes and valves this is to connect with all the cylinders. Not more than fifty pounds pressure of air to the square inch are required, and even that will give nearly twenty thousand pounds of lifting force (more than twice as much as ordinarily required), if the cylinders are made with a diameter of twenty inches, so that the piston-head would contain nearly four hundred square inches. The inventor intends to give the sections such a grade at the outset or highest point as to secure for the cars a high momentum in starting, and then to reduce this grade gradually towards the lower end of the incline, so that the track would in reality not be a straight inclined plane, but cycloidal in form. * * Passengers are to reach and leave the cars by means of a staircase, twelve and a half feet in perpendicular height, and from here they are to be elevated with the car to the top of the incline."

Treatment of Wood for Paper Making.—The *Mechanics' Magazine* describes Cattell's improved process for this purpose. We condense as follows: The wood, in fine shavings, is first washed in cold water. It is then placed in a bath consisting of a solution of borate and phosphate of soda, potash, or ammonia, in the proportions of three lbs. of the borate and one lb. of the phosphate, together with one quart of benzole, or other volatile solvent having an action on resinous matters, and not soluble in water, to every cwt. of the material to be operated upon. The bath is heated until it boils, and is kept at that temperature for six hours with continuous agitation, until on removing a small portion of the material, and applying to it chlorine water, it is found capable of being readily bleached. The wood is then removed from the bath, washed, and again boiled for four hours in a bath consisting of alkaline sulphides. The liquor is then drawn off, and the material is drained without exposure to the air, and subjected to the action of sulphurous acid, until the alkalies are converted into hyposulphites, when it is thoroughly washed, and converted into pulp in the ordinary way.

Breaking up old Cannon.—To reduce these to manageable size for re-melting, powder, nitro-glycerine, wedges, the expansive force of freezing water, and various other means, have been tried. The *Tribune's* Buffalo correspondent writes: "Here they are cut in two by a continuous stream of molten iron, which wears away the iron as a stream of hot water would eat into a mass of ice. The gun is rolled upon a frame in front of and level with the furnace mouth. Then the muzzle end is shoved in as far as possible among the other iron, the opening filled up and luted around the gun, the end of which is melted off. At the next change it is shoved in another length, and is thus reduced until the breach can finally be rolled in and thus finished without any more expense than with pig or scrap iron."

Separating Brass and Iron Filings.—A late French invention is a machine for this purpose which will run through in an hour half a ton of mixed filings and borings. These are thrown into a hopper, whence they fall upon a revolving drum, which has upon its surface iron bands in contact with horse-shoe magnets within. The iron particles adhere to these bands, and are removed by a revolving brush beneath. There are two of these drums, and the iron and brass particles are finally delivered into separate receptacles.

The Whitworth Gun Metal.—We clip the following from an article in *Engineering:* "The great merit of the manufacture of the Whitworth metal consists in putting the molten steel under extreme pressure, and so expelling from the mass all those air bubbles and gaseous spaces which cannot otherwise be got rid of by the ordinary processes without larger proportions of carbon than are often consistent with due ductility. It is essentially a mechanical process, applicable to molten metals whatever their chemical constitution, but most useful in the case of low steels. The details of the system have no doubt taxed all the mechanical resources of the inventor, but the above is the simple result. The process has the advantage of not being in competition with the Bessemer or any other process of purifying and carbonizing iron. What it will compete with is the method of endeavoring to make an unsound ingot sound by hammering, or that of seeking to produce sound masses of ductile metal without hammering."

The Clip Pulley.—This is an English invention which has been introduced in the Pennsylvania iron mines. The circumference of the pulley is set throughout with pairs of movable jaws. The amount of motion in these jaws, and hence the amount of clutch upon the rope, is proportioned to the strain upon the rope. The especial advantage attending its use is, "that it entirely does away with the sawing action of the rope in the ordinary V groove of a pulley—the clips laying hold of the rope with an amount of grip proportionate to the pull upon the rope, holding it absolutely fast for the moment and afterwards completely releasing it as soon as it arrives at a point where it is tangent to the pulley. By this means, any power that is desired can be transmitted by the clip pulley, without involving either the loss from friction or the wear and tear of rope attending the use of the ordinary grooved pulley."

A Tellurion.—A Georgia paper notices a machine lately brought out by a citizen of Atlanta, which is to be manufactured for sale by a company organized for the purpose in Hartford, Conn. The cost of perfecting it, in time and money, was some $80,000. We quote: "It is believed to be the only tellurion which presents the movements of our earth and moon precisely as they are in nature. The earth is seen to travel, not as in most exhibitions of the orrery, or planetarium, in a circle, but in the ellipse which its orbit actually describes. It shows with precision, at a glance, the movements which produce day and night and the changing seasons. The movements of the moon are clearly shown—its exact revolutions, its crossing of the path of the earth, and the effect upon it of the attraction of the sun, and of the earth."

Coppering the Wire for Cushion Springs.—The iron wire used so extensively for this purpose is immersed in a solution of sulphate of copper for a short time, during which a thin film of copper is deposited upon it. It then goes through the draw-plate for the last time, and the necessary hardness and elasticity are given it, while at the same time it is protected from oxidation.

Another Brake.—An American invention recently patented in England is so arranged that a pair of "brake-wheels" are brought into contact with the running wheels and with the rails at the same time. The contact with the running wheels causes the brake wheels to revolve in one direction, while the contact with the rails gives them a tendency to revolve in the opposite direction.

Charcoal Bells.—M. Sidot carbonized wood in the vapor of sulphide of carbon, obtaining charcoal, which, when struck, was as sonorous as a piece of metal. He then got a bell turned in wood, carbonized it in the same way, and has an instrument which gives a sound like that of a silver bell. The carbonization is only superficial, and the bell, therefore, not very brittle.

Morocco Manufacture.—A new form of the tanning process consists in attaching the skins, in the form of bags, to nozzles, from which the tanning liquor is forced into them under pressure from a reservoir above—the liquor slowly filtering through the skin, and thereby permeating its pores.

Scientific Progress.

Philology and Darwinism.

F. W. Fnrrar epitomizes, in *Nature*, a pamphlet by Prof. August Schleicher of Jena, upon the parallel between the science of language and the Darwinian theory of the origin of species. We quote detached and condensed paragraphs:

"Prof. Schleicher regarded languages as natural organisms which, in accordance with definite physical influences and independently of human will, are produced and developed, grow old and die, and, therefore, manifest the series of phenomena to which we give the name "life." * * Mr. Darwin has constructed an ingenious diagram to illustrate the immense scope which must be allowed for gradual divergence of characters in animal and vegetable species derived by natural selection from an original genus. Prof. Schleicher has made an exactly similar table to serve as a genealogical tree for the Aryan families of language. But here the philologist has a distinct advantage, and the study of his results may be most suggestive to the naturalist; for the Darwinian diagram is to a great extent ideal and hypothetical; while the table of languages is an expression of indisputable discoveries. * *

The rudest forms of the most developed language have sprung by insensible derivation, from phonetic signs as vague, simple, and monosyllabic as those of Chinese itself. * * The ultimate roots of the Aryan languages closely resemble in character the actual words of those languages which have remained to this day nearly in their primitive condition. Such roots may, without fancy, be called speech-cells, in which the rudiments of all special organs are implicitly *involved*, but in which they are as little *developed* as in the germinal vesicles which represent the earliest forms of animal and vegetable life. There may have been multitudes of such sound-cells, as it were, from which different families of language have sprung by special lines of development, just as, according to the Darwinian hypothesis, many primordial cells, presenting a close similarity, may have been the earliest rudiments of all living organisms.

In speaking of the extinction of species and the struggle for existence, Mr. Darwin uses language which may be applied—without even verbal modification—to the phenomena of languages. Here, no less than in the animal and vegetable kingdom, the dominant forms of the prevailing groups tend to leave many modified descendants, while the imperfection of the weaker groups leads to their gradual disappearance. And in consequence of the extinction of languages many *intermediate* forms have perished; the primitive relationships have been disturbed by all sorts of external influences, and consequently languages radically different are now found existing side by side. All this represents a condition of things precisely similar to that which prevails in animated nature."

The Germ Theory of Disease.—The following is from a report of the discussion at a late meeting of the Polytechnic Association of the American Institute: The researches of Dr. Hallier, of Jena, were alluded to, and his conclusions in regard to the germs formed in the bile of cattle dying of the Texan cattle disease stated. This distemper answers to the yellow fever in the human system. In the bile from these cattle were found germs which not only lived, but grew and increased after the manner of those in yeast. It was stated that their development was largely influenced by the circumstances in which they were placed, one form being found when the growth was in carbonaceous substances, and another very different one when in substances containing nitrogen. Another interesting fact was stated, showing a close resemblance between the highest developed form of these germs, and those found in syphilitic diseases. Further developments resulting from close study of these germs may throw light upon the development theory.

Glaukopyrite—This is a new mineral, described by Prof. Sandherger, who discovered it in pieces of calc-spar from Andalusia. It belongs to the group of arsenical pyrites. "The color is light lead-gray to tin-white; the streak grayish-black; hardness, 4.5; specific gravity, 7.181. In contact with the air, it tarnishes slowly, first assaying a blackish, afterwards a yellowish-brown, and finally a blue color."

Experiments with Magnets upon Plants.—The following is from a recently published pamphlet by J. Vansant, M. D.: "I took three tulips in full bloom, flowers red, growing in the same pot within four inches of each other. These plants, which I shall designate as A, B, C, were about equally vigorous, almost exactly of the same size, and were kept in a light room at a genial temperature. If there was any advantage in vigor, it was in favor of A. By means of a steel-bar magnet, capable of lifting with one pole about an ounce of iron, I applied the southward end to tulip A, drawing the pole slowly from the surface of the soil to the top of the plant along the stalk and larger leaves, and repeating this manœuver for three minutes. I then made a similar movement over tulip B, but substituted the northward end. Tulip C was left untouched. Almost immediately there was a contraction or shriveling of the petals visible in both of the plants touched, but especially in A. Soon, however, the contraction disappeared from B, while in A it continued. About twelve hours afterwards I placed a small straight magnet four inches long by one-sixth of an inch in diameter, so that its + pole, resting against the scape of A, and its — pole against that of B, should keep up the same kind of magnetic action as first applied; and the instrument was left in this situation for 36 hours. At the end of that time the flower of A was very much withered and evidently dying. The flower and leaves of B, on the contrary, looked as fresh and of as good color as those of C, which were untouched. After eighty hours from the beginning of the experiment the flower of A was quite dried up, while that of B, though more shriveled than C, was far less withered than A. The green leaves of B appeared just as healthy as those of C, but the leaves of A were more than ever curled and pale."

Temperature of the Deep Sea.—In a recent lecture at the Royal Institution, Dr. W. B. Carpenter, V. P. R. S., gave the result of some recent dredgings in the deeper parts of the Atlantic, farther south than those made a year ago. The work done proves that after a depth of 200 or 300 fathoms is passed an enormous difference in the temperature of the water quickly takes place, and the area of the bottom of the deep Atlantic is covered with water only two or three degrees above freezing point, and this cold area is full of animal life. They dredged in water 500 fathoms deeper than that from which the Atlantic cable was raised, and they brought up great quantities of mud from a depth of about three miles. This mud contained plenty of the higher forms of life, including mollusca and cretacea, with well formed eyes. Temperature seems to exert a much greater influence upon animal life in the sea than depth. Hot weather superheats the surface water to a depth of about fifty fathoms.

As to the icy cold water at the bottom of the North Atlantic, it is a question which further research must solve whether this cold water does not come more from the south than the north pole, for there is so much water and ice near the former, and so much land near the latter. As the north pole is approached the Atlantic narrows very much, so that cold water coming from that region must be very much diluted as it flows southwards, because of the large area over which it has to spread itself. There is reason to believe that the water in the very deep sea is everywhere very little above its freezing temperature; it is therefore no wonder that arctic species are found in equatorial geological formations.

Heat and Force not to be Dissociated from Matter.—"Heat being a form of motion, a force, the difference between sensible and latent heat is, that the molecular motion of the first is communicable to the thermometer, while the latent heat is that peculiar molecular vortex motion, required to keep a body in the gaseous or liquid condition. This peculiar motion is not communicable except when driven out—that is, when by condensation or otherwise, the space required by the molecule in keeping it up, is contracted or sufficiently diminished. Even latent heat being thus a motion of matter, a store of force, a motion of material molecules ready to show itself undiminished at any time, heat cannot be asserted ever to become dissociated from matter. As further all mass motion is convertible into molecular motion (heat), and as in the essence of the true modern conception they are not only convertible, but, in a certain sense, identical forces, we cannot dissociate force from matter, without screwing up our imaginations to a high metaphysical tension."—*Dr. Van der Weyde*—*Chemical Repertory.*

Mining Summary.

The following information is gleaned mostly from journals published in the interior, in close proximity to the mines mentioned.

California.

ALPINE COUNTY.

Items.—*Miner*, May 7th: Mt. Bullion tunnel is encountering very hard rock, yet is pushed with energy....M. C. No. 3 is making good progress in ore of low grade. ....Air pipe of galvanized iron has been put in the Silver Glance tunnel....Ore from the Pennsylvania, three tons, was taken to Reno this week to be worked by Stetefeldt....It is reported that the machinery for the Schenectady will be here at an early day....We learn that the survey of Mountain No. 1 has proved satisfactory, and that as soon as giant powder can be obtained work will be resumed.

Leviathan.—*Chronicle*, 7th: The erection of the smelting works has commenced, but it will be six weeks before they will be ready for operations. Next week coal burning will start up again.

Better.—Pennsylvania ore steadily improves, and that taken out this week is much richer than that sent to Reno on Monday.

Relocations.—As there are many claims upon which no work has been done for two years, several relocations have this week been made.

AMADOR COUNTY.

Oneida.—*Ledger*, 14th: Another satisfactory clean-up was made last Saturday after a run of two weeks.

Kennedy Mine.—The owners, for want of water at their own mill, are having rock crushed at the Maboney and at the Kearsing.

CALAVERAS COUNTY.

Angel's Camp.—Cor. of *Chronicle*, 14th: The Roanoke mine, owned by Jim and Joe Matson, has turned out a chunk weighing $1,123, with smaller ones ranging from $50 to $250. The Angel's Quartz Co. has pierced to the depth of 400 feet, the quartz paying from $40 to $100 per ton.

The Stickle's mine, on the same lode, had a good clean-up recently. Besides these there are 15 arastras working daily, and all paying.

Railroad Flat.—Cor. of same: Whisky Slide rock shows any amount of free gold, notwithstanding the raids upon the pile by specimen seekers. The shaft is 50 feet deep. The lead measures seven feet between the walls, and the rock prospects well. The owners have exhausted their means, and work has stopped.

The Petticoat mill, after a short run on rock from the Poe mine, cleaned up a large amount; and also realized handsomely from another lot crushed recently.

Mr. Burr, lessee of the Petticoat mill at Railroad Flat, has made the following proposition to the miners of the district: He agrees to pay them $1.25 per day for working their own lodes; the expense of hauling the rock to the mill to be equally borne by himself and them; he will do the crushing and give the miners half the proceeds.

EL DORADO COUNTY.

The Prospects.—Placerville *Democrat*, 14th: The evidences of prosperity are daily increasing; we constantly hear of some new mining strike, and it is more a matter of surprise that a man has not, than that he has, a good paying claim. And the fact that we are going to have a new ditch is no longer problematical.

Pleasant Valley.—Thos. R. Young and McLellan, from two months' washing, have cleaned up $2,600.

Pi Pi.—McKinney & Co. cleaned up three months ago, 140 ounces, after two months' run. During the past week they have cleaned up, after three months' run, between 50 and 60 pounds of gold, and are not entirely cleaned up yet. Steadman & Co., same place, have averaged $5 per day per hand, in opening their claims, and are certain of big pay when water comes next winter. Smiley & Co., for three months, have made $10 per day per hand at same place.

Georgetown.—Cor of same: Parties have been here from San Francisco negotiating, and there is a fair prospect that the Eureka will be sold. In the event that no arrangement can be made, the present owners intend immediately to start the mine. There is an eight-stamp mill on the mine with everything necessary for working. The rock abounds in sulphurets, which have been found rich. The Woodside mine still remains in *statu quo*, the owners having no means to work it.

Water promises to be short. Claims which at this season usually have abundance of water, are now about to shut down for the summer.

INYO COUNTY.

Cerro Gordo.—Cor. of *Territorial Enterprise*, May 3d: The owners of the San Felipe are setting up a claim to the Union vein, as being one and the same, and are taking out ore from it. From the Defiance Co's shaft H. W. Gould and others are taking out rich galena. Ditto Mat. Gibson on the Front lode. The Jefferson Co. have been taking out very fine ore, and are now running a tunnel to tap the bottom of their shaft 65 feet deep. Mr. Williams, one of the owners, informs me that they have taken out of this shaft 275 tons of galena ore, which assays $120 per ton in silver and 70 per cent. in lead. Their location was made about the 8th of November, 1869. J. H. Phillips, formerly foreman of the Chollar-Potosi, has a contract with the Jefferson for taking out ore. The Buena Vista Co. has a tunnel in 300 feet, and has a prospect of striking the ledge in a few more feet. The La Depresa Co. has a tunnel in 138 feet.

MARIPOSA COUNTY.

Mariposa Mine.—*Gazette*, 13th: Workmen struck an exceedingly rich vein in the lower level last Monday, and the rock improves as they go down. The vein is nearly four feet in thickness, and shows gold freely.

NEVADA COUNTY.

Eureka.—Grass Valley *Union*, May 11th: There was a semi-monthly melting at the mine yesterday. The gold melted was from the mill alone and does not include anything from sulphurets, nor from the batteries. A 12-days' run gives $26,300.

Perrin's.—Same of 12th: The runs of Perrin's mill for the last four weeks make a total of $5,409.62. During the time 175 loads of rock were crushed.

Bowery Mine.—Same of 15th: The new pumping and hoisting works started up yesterday. Every thing worked well. The shaft is down 100 feet. The rock has paid $83 per ton, on an average, counting all taken out. The ledge is from 8 to 16 inches thick.

Prospecting.—On Gold Flat a large amount of prospecting is being done for quartz. Several of the ledges have yielded first rate rock. In addition to this the companies along Deer creek, as high up as the Cascades, are prospecting for gravel, with splendid indications. Other enterprises are being pushed forward at Cement Hill and other points.

Sucker Flat.—The Pittsburg Co. have completed a bed-rock tunnel 1,800 feet long, raised a shaft, and will commence washing in a few days. The Timbuctoo tunnel is in 750 feet. The Blue Point tunnel of Crary, O Brien & Co. will be through in a few months. Other companies are making good progress.

Bloomfield,—Same of 12th: The North Bloomfield Gravel Mining Co. are working 20 men in their claims. The company will in a short time commence work to connect the upper end of the new ditch with their big reservoir at Bowman's.

Blue Lake.—This district, in Meadow Lake township, seems to be attracting attention. Recently a number of locations of ledges have been made, in which San Francisco parties are largely interested.

Diamond Creek.—Same of 13th: The miners have had a short but lively season. Five companies have been washing, but the scarcity of water will soon force all of them to stop.

Lecompton Mine.—Same of 14th: A company of five working miners, who are acquainted with the ledge, have taken a contract to work the mine on shares for four years.

Omega.—We learn that 12,000 inches of water per week is used at Omega, and this is insufficient to supply the demand. The ditches are all running full, but this will only be for a few days longer.

The Prospect.—The present season bids fair to be one of the greatest in its yield in some years. The quartz interest is extending its area. We hear of many old claims started again, and many new ones opened. Several very heavy operations, which have been for years getting ready, will be at work this season.

Forest City.—We learn that things are assuming a lively appearance again. The re-discovery of the great lead from which such large amounts of gold were taken in years gone by, give an old-fashioned appearance to the town. The rich quartz ledge recently struck below Rock creek is supposed to be the same from which specimens were taken by Mr. Cornish a year since.

Graniteville.—Cor. of same, 13th: The Sweet ledge is reported to be in the hands of the Watt Brothers. They are down 300 feet on the Jim mine, and have a ledge four feet wide, of rock which must pay $25 a ton. The mill started up 10 days ago. The Banbury ledge has been worked all winter, and paid good dividends. They employ 30 men. The Birchville mine has been incorporated. They are down 150 feet with their incline shaft. At the Star mine, Pendleton & Co. have 200 tons of good looking rock out. The mill is being repaired.

PLACER COUNTY.

Ophir.—Cor. of *Herald*, 12th: Our mills cannot crush the rock as fast as the miner raises it....They have not taken out quartz from the St. Patrick this week, and will not for several days. Mr. Eaton has let a contract to sink the shaft deeper. The quartz in sight in the bottom is as rich in gold and sulphurets as ever....There are several companies south of Ophir, a short distance from town, that are getting good prospects....The Empire Co. have a number of ledges included in their purchase that look promising, and intend to go to work on them very soon.

SAN DIEGO COUNTY.

Julian District.—San Diego cor. of *Alta*, May 10th: The first quartz mill arrived yesterday. It has a capacity of crushing 25 tons of rock in 24 hours, and is owned by William McMillan and others. It will be put up at once in the Julian District. Several ledges are making a better showing. At a depth of 40 feet the rock is better and the ledges wider than on the top.

SHASTA COUNTY.

Horseshoe Bend.—*Courier*, 14th: If the logs and other obstructions are removed, and no rain falls for three weeks, the tunnel will carry about all the water in the river, and leave the channel dry enough to work for several miles. It is hoped that some effort will be made to work the claims this summer.

SIERRA COUNTY.

Mining Near Gold Lake.—*Messenger*, 14th: At Illinois Camp Steilman & Co. are taking out good pay. Near them Limprich Bros. are getting ready to hydraulic. Near Woodchuck, Culver & Co., Nova & O'Niel and Jackson have apparatus for hydraulicing, in place. Sol Bahb, at the mouth of Woodchuck ravine, has a hydraulic and derrick in operation. William Wilburn will put in a hydraulic. There are half a dozen other companies getting ready. The snow is quite deep yet.

Port Wine.—Cor. of same: The Monte Cristo boys are taking out big pay, and to-day word came down that they had found a 10-ounce specimen worth $200. The Union boys are taking out heaps of dust. Those in the Eagle are doing better lately.

Goodyear's Bar.—Quite an excitement has existed during the week over the discovery of an extensive gravel deposit, a mile below town, on the north bank of the river, 45 to 50 feet in depth, and paying from five to ten cents to the pan throughout.

SISKIYOU COUNTY.

Cottonwood.—Yreka *Union*, 13th: Jones & Barton of Humbug are getting out timbers for a quartz mill at Cottonwood, to which they will remove their machinery. The Norfolk and Lodi ledges will supply the quartz for the mill. It shows a great amount of free gold. It, however, has never been prospected, except in a hand mortar. The mill will be running early in June.

Sugar Creek.—O'Shea & Doll, on Tiger Fork, have found a ledge which at the depth of five feet shows a vein 2½ feet thick. It prospects well.

French Creek.—The Spidell Co. have run a tunnel and struck the ledge 100 feet below the surface. It looks well.

TUOLUMNE COUNTY.

Confidence Mine.—Sonora *Democrat*, 14th: Seven days' crushing cleaned up 735½ ounces, or about $14,000,—an increase of $6,000 on the run of last week.

Colorado.

Whale.—Central City *Register*, May 11th: The mill will have Bruckner cylinders, Freiberg barrels, Bertola pans, and a steam stamp mill. It will be completed by the middle of July.

Hukill Gulch.—The Fairmount lode has a shaft 100 feet deep, a crevice at the bottom ten feet in width, and a pay vein 30 inches. The first-class ore has sold for $150 a ton. Forty-seven assays average $209.73 per ton.

Mr. Baker is working the Shaffter lode. A test run of five or six tons made at the Fairmount arastra gave a yield of 2½ ozs. per ton. The Fairmount mill is shut down for completion.

Womack & Seaton.—Shaft 268 feet deep; crevice in the upper level ten feet wide, carrying a ten-inch vein of first quality ore, averaging 100 ounces silver and two ounces gold per ton. The eight men employed mine two tons every 24 hours.

St. Clair Mills.—Grove & Haskins are running this on gold ore by the Paul process.

Empire.—George Munson is running the Knickerbocker mill on ore from the 10th Legion lode. The last lot yielded five ounces gold per cord.

California Gulch.—Thomas Starr has been all winter ground sluicing, and has taken out 100 ounces of fine gold. George Henderson has been sluicing with good results, The lodes are looking finely. The Pilot is again yielding pay, as also the Lincoln and Printer Boy.

Payne's Bar.—Morilley & Anderson have struck it rich, and are averaging an ounce to the hand a day. Wednesday two men took out five ounces.

Fitzpatrick & Sariolle have a pay streak that averages an ounce of gold to the foot. Week before last three men, in six days, took out 17 ozs. 10 dwts.

John Collom has his smelting works at Swansea under full headway, and has commenced work on ore from the Griffith lode. This mill has a dressing capacity of 20 tons a day, while the furnace can smelt six tons every 24 hours.

Bullion.—*Herald*, 11th: The shipment for April from Central City was $78,000.

Potter & Holly are running their 15-stamp mill on ore from the Forks, Jones, Burroughs and French lodes. The Jones is yielding 11, and the French 16 ounces per cord. This mill has taken out $5,000 in the last three weeks.

Coaley & Gilpin.—The mine turned out six bricks of silver last week. Their weight was 247 pounds, worth in currency $4,000.

Prize.—The ore is yielding 6 oz. 15 dwts. per cord. This is worth $125 per cord.

Items.—Georgetown *Miner*, 5th: The Brown Co. shipped yesterday, a button of silver weighing 216 pounds troy; coin value, $3,369.60. The German Reduction Works, Huepeden & Co., shipped a silver brick weighing 1,073.80 ounces; coin value, $1,035.68; product of second-class Terrible ore.

Cascade.—This lode is thought by some to be an extension of the Terrible. The crevice is four feet wide. The ore varies in richness from $163 to $450 per ton.

A sample of Sunhurst ore assayed $1,816 per ton.

Idaho.

New Discovery.—*Statesman*, May 10th: Messrs. Montgomery, Alexander & Gibbs, who have been prospecting on Boise river all winter, finally struck a rich gulch on this side about ten miles above town, near Sheep creek, which prospects from twenty-five to fifty cents to the pan, coarse gold. There are several other gulches near by that also prospect rich. Nine hundred dollars have been taken out of the discovery claim.

Montana.

Silver Bow.—*New North-West*, April 29th: The water troubles are adjusted on a basis of 75, 60 and 45 cents per inch for 24 hours.

Rocker.—Cor. of same: The mild weather has given a supply of water, and the bars and gulches are alive with men busily sluicing. Although our population has increased considerably, there is a constant demand for labor. Wolverton & Liddle bought 300 feet in McMinnville bar for $2,000, and will soon have a hydraulic in operation. Owen & Co. are working day and night on their ground. A new discovery was made a few days ago near the head of Rock gulch. Hawkins & Co. are now the owners of the larger portion of the gulch.

Cedar Creek.—Mr. Botiel left Louisville April 21st. He estimates the number of men at Cedar creek at 2,000. Twenty strings of sluices were running. Wages are $6. There are many unemployed men in camp. Discovery company would have three strings of sluices running Monday. With four men to the string, two shoveling in, it yields $45 to $50 per day to the man. The pay streak is 108 feet wide. No. 8 above yielded $90 per day to the hand for first three days. Eight miles of the gulch will average $15 per day to the man. Diamond gulch is paying 6 cents in the gravel; no bed-rock yet struck.

Pilgrim Bar.—Same of May 6th: There are in the camp about 140 men, and 17 companies will work hydraulics and ground sluices. These will produce from $1,000 to $4,000 each per week.

Pioneer.—Some 15 large companies and a number of smaller ones will work this summer. The ditches will furnish 3,000 or 4,000 inches of water, and the snow on the Gold Creek mountains promises a continued supply. The Chinese, some 300 of them, have purchased a large number of claims, paying cash. There is some feeling on the subject.

BEAR GULCH.—There are some 250 men working, and 150 in the side gulches. Water is plenty, and there is not an idle man in the camp.

BUTTE.—Humphrey & Allison's ditch is carrying 600 and John Noyes' 250 inches of water. There are only 50 men in the camp, while 150 are needed. Wages are $6 for day and $7 for night hands.

WASHINGTON GULCH.—*Independent*, May 7th: We learn that the mines are bountifully supplied with water, and miners taking out large amounts of dust.

HENDERSON'S.—The miners are all working. They have plenty of water, and are doing well.

HIGHLAND.—R. D. Leggat reports that the miners have just got to work. Quite a number of men are needed. The fluming companies have resumed operations, but as yet water is scarce. The arastras of the Nevins and Only Chance companies will start up next week. The Nevins Co. are still pushing their tunnel. Only Chance are working on their shaft. The owners lately refused $20,000 cash for their mine. Dickey & Co. have seventy tons out that is very rich. They are erecting an arastra.

CABLE CITY.—Mr. Cameron informs us that the new steam hoisting and pumping works work admirably. The shaft is being sunk rapidly.

Nevada.

COPE DISTRICT.

ARGENTA.—Elko *Independent*, May 11th: The owners contracted to furnish the Reinhart & Drew mill 2,000 tons of ore,—not 200, as heretofore stated. The stage brought down on Monday 300 pounds Argenta bullion.

COPE DUST.—Oppenheimer & Co. received this week $1,600 worth of gold dust from Mountain City. The estimate of the dust taken out daily is $600.

ESMERALDA.

COLUMBUS.—Cor. Sac. *Union*, May 3d: Eaton's mill has been running two weeks. He has shipped 400 pounds of silver bullion, and will ship more this week. The rock worked was from his Baluarto mine.

The Pioneer mill has been working refractory ore, and has saved 80 per cent. of that roasted and 65 per cent. of that not roasted. In a week they expect to have the mill running steadily.

HUMBOLDT.

ITEMS.—*Register*, 14th: The Silver Mining Co's mill at Unionville has shut down, and work upon the mine suspended for the present....Isaac Miller has discovered a very rich ledge in American district.... Aiken & Co., of Raspberry, have discovered a rich mine in Sierra district. The ledge is several feet wide.

REESE RIVER.

MINERAL HILL.—Cor. Elko *Independent*, 14th: Our camp is reviving. All the mines are worked, and the ores improve. The Manhattan Co., of Austin, has let contracts for the erection of a Stetefeldt chlorination furnace.

WASHOE.

HALE & NORCROSS.—Gold Hill *News*, 14th: Daily yield, 160 tons; principally from the lowest level. At this point the body of ore is the best ever yet found in the mine, being not only of high grade, but of great extent. It bursts out 50 feet in width and is worked thus far 130 feet. This level, 1,182 feet from the surface, is kept perfectly drained by running the pump two hours out of the twenty-four.

OCCIDENTAL.—The lower tunnel is still driven ahead to connect with the winze from the upper mine. This will take three or four weeks.

CROWN POINT.—The incline from the 1,000-foot station is 87 feet deep to-day, but the rock is hard. The daily yield is 65 tons from the upper levels.

GOULD & CURRY.—Yielding 70 tons daily of good ore from the old mine. The bullion receipts for April footed up $48,721.80.

SIERRA NEVADA.—This is about the most regular in its yield of any. The surface deposits seem inexhaustible.

OVERMAN.—Daily yield 125 tons. The body of ore found a few days since seems extensive.

HOPE.—Daily yield 30 tons, all of which is worked. The lower level continues looking better, and the general yield is $20 per ton on the average.

KENTUCK.—An improvement is manifest during the past week. The daily yield is 50 tons.

CALEDONIA.—Yielding 30 tons per day of fair ore from the 200-foot level.

YELLOW JACKET.—This mine is all right again, giving its regular yield of 350 tons per day—200 of good grade from the lower levels, and 150 of low grade from the upper levels.

CHOLLAR-POTOSI.—Daily yield 200 tons of good ore. South of the old Blue Wing a very excellent and extensive body of ore has been developed. This new resource is designated the Belvidere section.

SACRAMENTO & MEREDITH.—The new mill starts up for the first time this afternoon.

VIRGINIA CONSOLIDATED.—The west drift from the 500-foot station is in 352 feet.

OPHIR.—The Ogden mill is run on ore from the south shaft of the old mine.

BELCHER.—The yield is the same, and the prospects for ore at the 730-foot level do not improve.

WHITE PINE.

ITEMS.—*News:* Bullion shipments for the week ending May 10th foot up $54,790. Tom Paine has been sold in Chicago, on terms similar to those for the Pogonip & Othello, the original owners retaining a large portion of the stock. Aurora South ships 60 tons ore per day. Noonday increases in richness, and the vein is 12 feet wide. Force of men reduced in Original Hidden Treasure, for some reason unknown to outsiders. Virginia has met with small bodies of exceedingly rich ore. Domingo has been incorporated, and the force will be increased. O'Connell has been incorporated. A lot of its surface ore milled $205 per ton. Miser's Dream will put on more men. Westford shows large quantities high grade ore. Erie, a base metal mine, has a shaft 112 feet deep, and a seven foot-ledge. John Steel, the owner, has contracted to deliver 400 tons ore at $60 per ton in Hamilton. Elko, also base metal, is shipping 100 tons to Santa Fé. A large body of rich ore struck in Aurora South on the 9th inst. Some of it was nearly pure silver. Col. Whepley and Capt. Boylo have leased the White Pine Mill.

STANFORD MILL.—The *News* has interviewed this establishment, and devotes some space to description. Every thing about it is very complete. The bullion shipment for 30 days ending May 15th, promises to be $70,000. Total since the mill was started, Oct. 28th, is $206,844, all from South Aurora ore.

RAILROAD TO ELKO.—The *News* urges action to this end, and shows that it would be a good speculation. Before the summer is over, the bullion and ore for shipment will be, at present rate of increase, 100 tons daily. To haul this would require 100 16-mule teams: and there being no return freight, the cost would be $50 per ton.

OUTSIDE DISTRICTS.—The bars of bullion brought in from the Parsons mill at Silver Park, on Wednesday, weighed 61 pounds, worth $1,087.21. Parties from Eureka report times improving rapidly, and four furnaces running. Col Cummings will erect smelting works in Robinson district

SILVER PARK.—*News*, 14th: Outside of White Pine, Silver Park promises to be the best district in Eastern Nevada. Two quartz mills are running within 400 yards of the principal group of mines, and charge only $30 per ton for crushing custom ore. Considerable work has been done among the claims opened. Magnolia has 80 tons of ore on dump. Liberty sunk a shaft 36 feet deep through $60 milling ore, and has opened a chamber 20x16 feet on the 36-foot level, with ore on all sides—horn silver, chloride, and some sulphurets. Ontario has an incline 25 feet deep, all the way through good ore. Wolverine has an immense body of good ore. Miners' Delight has a shaft down 20 feet, through a mass of rich ore. Great Eastern has a well-defined ledge of high-grade ore. Onglendor has a shaft 80 feet deep, at which point the ledge is 11 feet wide and the ore good. The Bradshaw, on Red Hill, three miles southeast, is the richest mine in the district, so far as known. A breast has been driven into the hill 20 feet, into a solid mass of ore, which will mill from $500 to $1,000 the ton.

NEW YORK has another project—viz: to construct a building or series of buildings for the approaching international exhibition on a much larger scale than ever before in that city. One of the parks is to be taken for this purpose, or, in case this is not allowed, a place will be selected on Long Island or, perhaps, Staten Island. The building will run around four sides of a square, leaving an interior space of some four acres for an ornamental garden. It is to contain the biggest picture gallery in world. A capital of $7,000,000 is said to be already raised for this purpose.

San Francisco Mining Stock Market.

As a general thing, the mining share market continues inactive, and during the past week the majority of stocks show a recession. The volume of business is fair, however, still exhibiting the absence of very extensive dealing by any other than inside speculators. White Pine stocks attract considerable attention, large sales of Noonday, Original Hidden Treasure and Mammoth having been effected.

HALE & NORCROSS—was in better request than last week, selling at a recession. During the week ending May 14th, 1,314¾ tons of ore were extracted—327 tons coming from the upper mine, and 987¾ from the lower mine. They had on hand in the dumps, 5,473 tons. On the 17th inst., the most northern breast, on the seventh level, was 120 feet north of the shaft. They are making slow progress, on account of the heavy breast of ore they are carrying, the same being about 25 feet wide. The cross-cut east and west at this point has not yet reached either wall. The south breast is now 20 feet south of the shaft, and they are opening this breast some twenty feet wide in the ore. The ore found in this locality is reported to be of excellent quality, and all the developments apparently promise well for the future.

CHOLLAR-POTOSI—sold to a large extent, at very uniform rates. They extracted 1,044 tons of ore during the week ending May 13th, the average assay from car-samples showing $52 20 to the ton; previous week the yield amounted to 1,069 tons. During the week under review 22 feet were added to the "raise" at the New Shaft. They expect to complete the entire distance and commence drifting from it in the course of the current month. On the 13th, $29,255 in bullion were remitted to the office in this city. The daily ore-slip of the 16th inst., states that 196¾ tons of ore were sent to four different mills.

GOULD & CURRY—under considerable sales, declined rapidly during the present week. They extracted 421¼ tons of ore during the week closing May 14th; average assays showing $51 35 to the ton; previous week, 580½ tons. On the 17th inst., $10,807 in bullion were dispatched to this city. At this date the cross-cut from El Dorado winze shows some good ore, which is not yet sufficiently developed to determine its value as a body. On the seventh station they are through the clay in cross-cut "A," the face of the drift showing quartz and porphyry. C. C. Batteman has been appointed Superintendent of this mine, in place of P. Deidesheimer, resigned.

BELCHER—was in the market to a fair extent. The ore-stopes above the 152-level have improved within the past week in quality, and recently a new "raise" has been completed from the 262 to the 152-level, which will afford access to the bodies of ore under the latter level. The north-drift on the 262-level, it is expected, will be extended to the body of ore near the Crown Point line in less than two weeks. From the 1st to the 16th inst., 1,019 tons of ore were sent to the Rhode Island Mill. They extract about 70 tons of ore per day. The bullion yield for the month of April foots up $31,698.

CROWN POINT—sold to a large extent. On the 15th inst. they resumed work on the main east drift from the 1,100-level, and said drift is now 720 feet from the shaft, the face showing hard porphyry. The incline from the 1,000-level is down 87 feet, the rock through which they are passing being hard, barren quartz.——KENTUCK meets with light inquiry. The receipts of bullion for May aggregate $21,226. They have some slight prospects of finding new ore deposits, and if not successful, it is likely they will suspend work for the present.——GOLD HILL QUARTZ levied an assessment of $20 per share on the 16th inst.——CONFIDENCE levied an assessment of $10 per share on the 14th inst.

IMPERIAL—has become quite active at a less figure than was obtained early in the week. On the 17th inst., the winze had attained a depth of 27 feet, the ore on the north side being four feet wide, but of a lower grade than they have been obtaining. The best of the ore is thought to be making east of the winze. Average assays of ore obtained from bottom of winze show $46 94 to the ton.——SEGREGATED BELCHER has been dull of sale. A letter of the 16th inst., states that they are taking out about 30 tons of ore per day. They sent forward $4,465 in bullion.

OPHIR—has also been largely dealt in, selling at a recession. The report for May 17th has the following: At shaft No. 1 the main drift is in hard porphyry and very wet. The south-west drift No. 1 is in good blasting ground; and No. 2 is in soft ground, making fair progress. Work at shafts Nos. 2 and 3, and drift from Walsh Tunnel, going briskly on, but barren of good results.——OVERMAN has been in moderate request. On the 14th inst., $12,600 in crude bullion was sent to the office in this city. It is reported that a fine body of ore was recently found on the 500 level, near the Segregated Belcher line, west of anything ever reached in either mine.——SIERRA NEVADA shows a yield of 408 tons of ore from the gravel deposits for the week ending May 14th.——JULIA levied an assessment of seventy-five cents per share on the 13th inst.——VIRGINIA (W. P.) levied an assessment of fifty cents per share on the 14th inst.——MAMMOTH (W. P.) will hold its annual meeting of stockholders on Monday, the 6th of June next.—*Cmmercial Herald,*

◆

QUITE an excitement was caused this week on Montgomery street by a successful but illicit financial operation. A check given by Treadwell & Co. on the Bank of California for the sum of $34.75 was altered to read $14,641.25, and then successfully passed on Hickox & Spear. The parties engaged in the operation have been caught, and most of the money recovered. The affair has, however, caused the ventilation of the rather loose way of some of the transactions of brokers and business men.

Mining Shareholders' Directory—Meetings, Assessments and Dividends.

Pacific Coast Pearl Fishery.

It is a long time since we have heard much of the Lower California Company, which obtained from Mexico a tract of land comprising forty-six thousand eight hundred square miles in that peninsula; and we now learn that the company is actively engaged in preparing an extensive expedition with the view of settling two of its provinces with American emigrants, and establishing a large ocean city. It is claimed that the company is armed with powers equal to those enjoyed by the great East India Company, which founded an empire. Its Superintendent and Governor-General is the Hon. John A. Logan, who has declared his intention of visiting the province, and giving it close personal inspection during the recess of Congress. The President of the company, the head-quarters of which is at No. 35 William street, New York, is Richard Schell; Wm. R. Travers is the Treasurer. Following which, we find the names of Gen. B. F. Butler, August Belmont, Wm. G. Fargo, Caleb Cushing, C. K. Garrison, John A. Griswold, John Anderson, Robert P. Lees, Ben Holladay, Robert M. McLane, Francis Morris, John McB. Davidson, Leonard W. Jerome, S. L. M. Barlow, Edward S. Sanford, J. B. G. Isham and Marshall O. Roberts.

This much is prefatory to discussing the pearl fisheries which exist in the Gulf of California. The Mexican revenue returns for 1869 show that the catch of pearls and pearl-shell along the gulf coast granted to the Lower California Co., amounted last year to the sum of $78,000 This is the value, as returned on the estimates made by the divers and speculators on the spot, but is clearly very short of the actual market value, which was probably four or five times the amount specified, and it is certain that not more than fifty per cent. of the whole catch is ever reported to the Government. The business is carried on in slip-shod, hap-hazard manner, which only excites astonishment that any returns at all are given. We have good reason to believe that the real value of the catch for 1869 was in the neighborhood of $300,000. But the business is attended with so many difficulties and obstacles that Americans soon get discouraged and abandon it. The divers are all Yackl Indians, in whom no confidence can be placed. They will contract to dive, but insist on a considerable advance, either in money or goods. After the advance has been made, the unlucky employer frequently finds himself some bright morning minus his divers, and is then compelled to go over the whole ground with a fresh set, only to be treated in like manner by the new comers. If well fed and well treated—things to which they are perfect strangers—they regard their employer as little better than a simpleton, laugh at his easy trust in human nature, and take themselves off without delay. It frequently happens that Indians who are not divers offer themselves in that capacity, requiring the advance, and, as the contractor cannot know the truth, he is as often duped. The real divers know their value, and take every possible advantage. Under these and other difficulties of a like nature, it is not singular that the pearl-fishery of this coast has not attracted a larger share of attention; but if conducted with system, and supported by the exercise of proper authority, it would prove most lucrative.—*Commercial Herald.*

◆

THE NATIONAL GUARD of this city, who are at the head of the militia companies, have a grand benefit on Thursday, Friday and Saturday evenings of this week at the California Theater. "Rosedale" and "Ours" are to be played, the whole company appearing in certain scenes. The performances will be (have been, by the time our readers see this notice) among the very best of the whole season.

Farming and Gardening.

Communications for this department are solicited from all parts of the Pacific States and Territories.

Nut and Timber Trees—The Pecan.

The pecan trade is lively in western Texas. The Victoria *Advocate* has heard of one merchant paying out $5,000 in less than one week for this spontaneous product of the forest. The average price paid is $3, specie, per bushel.

The above extract has a bearing when applied to the wants of this State. The pecan tree is indigenous to western Texas, which has a climate in many respects like the coast country of California. It borders on the streams, and occupies the rich alluvial soils such as the plain tree, the willow, the cottonwood and mammoth oaks of our State best like. When growing in clusters and groves, it is very tall, the trunk is straight, and the timber excellent. When scattered along the streams, it is quite spreading in its habits. Everywhere it is a grand and beautiful object, inferior in appearance to no deciduous tree. Its timber is valuable. It resembles the hickory, but is not equal to it in toughness, although it is superior to ash timber. It is a very prolific bearer, and its fruit is equal in richness and excellence of flavor to any walnut.

California is capable of producing all the hard-wood timber that she will ever need; and there is no surer enterprise open to aspiring capital and to that steady, constant and successful spirit of enterprise that is willing to labor and to wait, than to set out forests of timber. Many of the Eastern hard-wood timber trees, the south of Europe and South American trees, the Australian trees, etc., in numerous varieties, may be grown.

Growing timber is no experiment, but a sure and certain success. And, among all the rest, the noble nut trees of America should stand ahead. The pecan is certainly one of the best. It is of rapid growth, and its fruit is quite as valuable as its timber. The writer has gathered the nut in its native groves, and knows of what he speaks.

This subject has frequently been discussed in the Scientific Press before, but it merits constant recommendation. Among all the various industrial interests relating to farming, none is of more importance to the State and the Pacific coast. Many a section of land that it would cost more to reclaim for the plow than it would be worth, might be utilized in this way. Mountain ravines and water courses now utterly worthless might thus be made more valuable than gold mines. The actual value of a grove of young timber and nut trees, and the increase in value as in size, would warrant the enterprise in the light of a venture or speculation. Thousands of farmers on this coast have localities which they should plant at once to nut and timber trees.

To avoid the depredations of squirrels and gophers, the nuts should be sprouted in boxes before planting, or else started in the nursery. It is better to plant the seed where it is to be grown than to grow the trees in nursery, as the tap root is essential where drouth of water ever prevails. California should make a large requisition on the State of Texas for the new crop of pecans, to be distributed equally among the land owners of this State.

Preserving Hops.—Much difficulty is encountered by growers and dealers in hops in preserving their quality for any considerable length of time while on storage or waiting for a market. It is stated in the *American Artisan*, however, that a process has recently been devised which accomplishes this desirable result in a very satisfactory manner. The apparatus appears to be a refrigerating chamber, in which the hops are stored and kept as near as possible at a given low degree of temperature, and nearly as possible free from dampness. Hops thus kept over an entire season are pronounced fully as good as when first baled. This fact, if it is such, is important; as in hop-growing districts the ability to hold over a stock of hops, without deterioration, when prices are low and the demand small, would rescue the profit of hop production from many uncertainties, especially in a country so distant from any large market as California.

Girdled Again.—It is stated that the orchard of Martin Green, of Benton Harbor, Michigan, the trees of which have already been reported as having been girdled and restored four times, has recently been visited and girdled for the *fifth* time! The excitement in the neighborhood, growing out of these repeated outrages, is intense. Somebody is either acting the insolent bravado, with a contemptuous nose-thumbing and taunting finger-shaking in the face of the community; or some one is engaged in a series of profound and persistent philosophical experiments to see how often an orchard can be thus treated without compassing its utter destruction—for the neighbors in the vicinity have made common cause with the proprietor of the orchard, and are unceasing in their efforts to save it. They turn out *en masse* every time it is girdled, and hasten as rapidly and skillfully as possible to apply the best known appliances for saving the injured trees.

Farming is a Science.—Unexpected things constantly arise to prevent the farmer from carrying out any given routine of plans; but a mechanic proceeds straight forward with his work, without let or hindrance. Hence farming is not a mechanical, but a scientific occupation, and should be classed as such.

The Reaper.

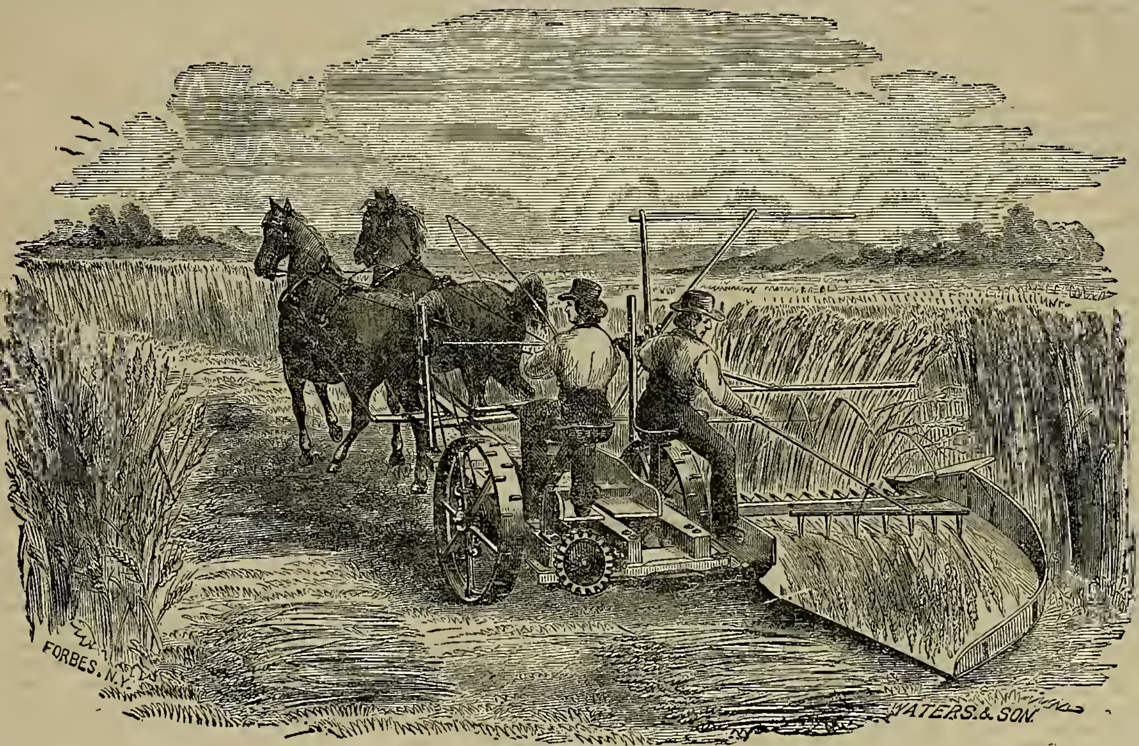
If we review the whole range of mechanical invention, we find no improvement which has so completely revolutionized the business it was designed to improve, as the reaper and the mower. By it the toil of the husbandman has been immensely lessened, and the labor of producing bread-stuffs reduced one-half. In this, as in most other departments of labor, the truth of the saying that "necessity is the mother of invention" has been fully verified. Whenever the urgent needs of men call for other than muscular help, inventive genius steps promptly in, and, quickened by the pressure of necessity, machinery is constructed, which, by a combination of forces working in harmony, performs the labor of dozens or hundreds of human hands by means of a single machine.

As harvest time is approaching in our State, where there is such opportunity for labor-saving machines, we propose to illustrate some of the best known devices which have stood practical working tests; and, in pursuance of this plan, we to-day present our readers with a cut of the Buckeye hand-rake reaper. The Buckeye machine has certainly achieved a high reputation in the West. Without declaring it better than any other, we can say that it has received the highest awards in a large number of field trials, and it has many testimonials as to its efficiency and durability. It was introduced into the market some thirteen years ago, and since then has received many valuable improvements. The following are some of the principal points for which the manufacturers claim especial advantages:

Two driving-wheels support the whole weight of the frame, gearing and driver; and side draft and weight on the horses' necks are obviated by the manner in which the machine is balanced. The wheels operate together or singly, so that short turns can be made to the right or left without clogging or stopping the knives. They have no cogs on them and no cog-wheel attached, but the gears are arranged at such a height above the ground as to avoid the danger of getting clogged by mud or sand. Pawls and ratchets are used to drive the gearing, and in backing, the knives cease to vibrate. Moreover, the pawls are held either in or out of gear by a spring, and, when out of gear, the wheels turn independently on the axis. The double-jointed cutter-bar adapts itself to all varieties of surface, entirely independently of the frame, over which it can be folded when not in use. The driver's seat is behind the cutters, enabling him to see their action at all times, and avoiding all danger of his falling on the knives.

The cutting apparatus has received especial attention, and the makers have decided upon using the malleable, steel-lined guard-finger and the three-and-a-half inch knife section, as the best. A leading wheel is attached to the inner shoe, to prevent the grass, over which it may pass, from being pushed along and clogging the machine, and to prevent the points of the guard-fingers from catching in the ground when passing over hollows and ridges. The outer shoe is of malleable iron, fitted with a steel plate for the knive to cut against, and with a steel runner. The track-cleaner is adjustable, and can be set at different heights, and both ends of the bar can be raised or lowered to cut at any desired distance above the ground. To pass obstructions, a lever is attached to the finger-bar and main frame, so that the driver can raise the bar easily, and a ratchet, connected with this lever, sustains the raised bar when desired. There is also a lever at the driver's side, by which to stop or start the gearing. The whole machine is made exceedingly light.

A self-raking attachment is added, and works well, being light, simple and compact; or, for those who prefer it, there is a hand-rake attachment. Our cut shows this latter, which can be easily understood. And, as in many places the dropper is liked the best, those who desire can have this style. Want of space prevents our speaking further of the details of this device, which is highly praised in the various parts of the country. Farmers desiring further information as to prices or details, can obtain the same by applying to the agents, Marcus C. Hawley & Co., 108 and 110 Front street, San Francisco.



THE BUCKEYE HAND-RAKE REAPER.

The Sex of Plants—The Potato.—In every variety of vegetable, as in the animal world, there is both male and female. It is also claimed by some that in many vegetables, as the potato, for instance, one end is male and the other female—the latter producing more abundantly than the former, and of better quality. It is also claimed by some experimentors that where the female or seed end of the potato only is planted, there will be no rot, and the yield will be much better than when both ends are mingled in the same hill. If any of our readers have, or should hereafter, experiment in this direction, we should be pleased to learn the results of their experiments.

Roots vs. Hay for Stock.—Many English farmers feed no hay to their work-horses. but keep them in high working order with straw, roots and shorts, and occasionally a little grain. When land is scarce and high, the raising of hay is poor economy, as the equivalent of ten tons of hay can be raised, in the form of roots, upon one acre of ground which would not yield three tons of hay.

A Woman's Crop of Carrots.—Mary N. Pinckney, of Onoudago, N. Y., raised, last year, seventy-three bushels of carrots on one-sixteenth of an acre of ground.

Mountain Agriculture in the Coast Range.

Last week I was in the Santa Cruz Mountains, and passed for some miles along their very summit. These hills are quite different in appearance, form, soil and vegetation from the Diablo range on the east side of San José Valley. The gravelly soils along the lower slopes of the Diablo range are of a harder and less friable nature than the same class of soils along the Santa Cruz borders; and while the grain in the former is perishing from drouth, the finest fields in San José Valley may be seen about the foot-hills of the Santa Cruz. Here beautiful lawns are naturally interspersed with timber, and in many places a dense growth of *chapparal* formerly occupied the soil, showing on the face of the land the superior quality of it. The superior abundance of forest and shrubbery evidently draws more showers, and the soil absorbs more rain than the soils opposite across the valley. Consequently, while one section is suffering from drouth, the other is luxuriant with promise. Throughout the valley the grain crop will be generally a failure; the only exceptions are in localities and under conditions already spoken of in a former letter. Along the summit of the Diablo range of hills, above 600 feet elevation, fine grain fields give promise of abundant harvests. Their well-rounded tops and intervening valleys offer a beautiful field for the plow. Wherever a claim has been effected among the hills and slopes of the Santa Cruz Mountains, orchards, vineyards, vegetables, corn and grain are cultivated with sure success. A greater amount of labor is required to clear and utilize the land in such localities; but its superiority for a general culture is everywhere manifest when once under the plow.

Standing upon the rugged heights of the Santa Cruz Mountains, over two thousand feet above the sea, a charming scene is unfolded to the vision. The immediate vineyards and fields; the forests of oak and laurel and redwoods; the lesser curious crags and peaks and spurs; the deep winding ravines, equal in beauty but not in grandeur the magnificent Sierras. To the west, the waters of the ocean melt into the vast horizon; to the east, is the beautiful valley of the Santa Clara, dotted with fields and houses and clustering trees and villages, and bounded by the checkered hills, whose grain fields carpet many a slope, and by the waters of the bay, nestling like a sleeping lake, while the peaceful scene elevates and enraps the senses with a sublimity and power of inspiration that simple language cannot convey.

S. H. Herring.

The Sunflower.

Years ago the leaves of the sunflower were used as a substitute for tobacco, and were said to be useful in asthma. They are excellent fodder for cattle. The seeds make good feed for chickens, besides yielding very superior oil. The stems make the very best bean poles, and if cut and kept dry, are good kindling wood. The leaves, whether green or dry, are eagerly devoured by horses or cows. We are not prepared to vouch for the correctness of the opinion that the sunflower is an absorbent of malaria, and, therefore, a preventive of fevers; but some persons who live on low ground cultivate it near their dwellings under this impression. Leaving this point of view out altogether, the plant is worthy of cultivation. One good quality has not yet been mentioned, but it is one of the most important recommendations—it affords excellent pasture for bees. Indeed the florets are so full of honey that the bees seem to be clogged with the excess of sweetness, and sometimes are so covered over with it that they become helpless, until their comrades come to their relief. We are persuaded that if a corner of a yard or garden has once become devoted to the raising of sunflowers, there will be no disposition in subsequent seasons to let the supply die out. Take it altogether, the sunflower is deserving of far more attention than has usually been allotted to it.—*Journal of the Farm.*

There is a small kind of sunflower that is indigenous to this coast which yields a rich seed. The native Indian women gather it every season for food. It makes a good chicken feed, but is not so valuable for bees as the larger sort, the well known old variety spoken of in the above article. Now that chicken raising is attracting so much attention in the State, the old sort should be given a trial. We are not sure but it would prove a good paying investment for oil, as well as for chickens and bees. The kind of poles and fuel that the stalks would furnish would be an item in some parts of the State. At any rate, as it is a useful product of the soil, California wants it, and can use it to advantage if any State can.

The Old-Time Country Garden.

In an interesting paper on "Flower Gardens and Flowers," in the *Old Guard* for April, we find the following graphic account of the old-fashioned country flower garden as it existed twenty or thirty years since. We are afraid that there are a few more of the same sort left, though the paper in question will do a good deal towards their improvement:

Every one remembers the old country garden—a little piece of ground, possibly a hundred feet, inclosed with a picket or puncheon fence, and taken care of mainly by the female part of the household. Beyond the mere rough digging or, perhaps, merely plowing in the spring, its cultivation and management were assigned to the women, the men and boys thinking it beneath their dignity to attend to anything so petty. It was generally a kitchen garden also. Here were grown the peas and beans, the lettuces and cabbages, the beets and carrots, the onions and crook-neck early squashes, consumed by the family. Along the fences were currants and rows of pot-herbs—the golden pot-marigold, thyme, sage, majoram and summer savory. The flowers were conventionally, of the same sort everywhere. Here was a bed of old-fashioned pinks, with reddish lilac blossoms and silver-green foliage; there a patch of johnny-jump-ups; a few scattered lady-slippers, single, and more given to leaf and stalk than to blossom; a stool of blue flags, and another of yellow and brown lilies; a few single hollyhocks, and, proudly towering over the rest, the tall and flaunting sunflower. This was all at some distance from the house, the space around which was open, and ornamented with the woodpile, the well, the ash-hopper and a dog house. Such were the gardens, and such the country houses, of years ago.

All this is, in a measure, changed. Even in far distant rural districts the traveler comes across garden after garden immediately around the house, where flowers of the rarer and finer kinds, arranged so as to afford harmonized masses of color, an external polychromatic decoration of the dwelling, marking the taste and refinement of those within.

Why do Bees Swarm?—At the recent Michigan Bee Keepers Convention this subject was discussed. Mr. Otis is reported as saying: The strongest instinct God has given to the honey bee is the love for storing honey. This instinct is so strong that she will remove the young larvæ from its cells and destroy it, that she may make room for the gathered honey. But she does not thus destroy the brood unless crowded for room by an unexpected rich harvest for honey. It is to guard against the destruction of the brood the queen-cells are started preparatory to swarming, which takes place as soon as one or more is sealed over.

The Creator has implanted in the queen-bee such unparalleled hatred toward a rival that but one normal queen is permitted to live in a family of bees. This hatred is so strongly developed that she will make divers attempts to destroy a rival while yet in the cell. But the worker bees keep the cells guarded, which so exasperates the old queen by the time one or more is sealed, that she rushes from the hive to find a new home, being accompanied by a majority of the colony. These are, therefore, the reasons why bees swarm: 1st. The want of combs to hold honey. 2d. To save the destruction of the brood. 3d. The hatred between rival queens.

What Our Young Men Can Do.—It would require but a few young men, with correct sentiments, to give to the great profession of agriculture, in any community, that character and respectability in the world which that calling so justly merits.

What I Know of Farming—No. 18.

Alkalies—Salt—Ashes—Lime.

I do not know a rood of our country's surface so rich in *all* the materials which enter into the production of the grains, grasses, fruits and vegetables, which are the objects and rewards of cultivation, that it could not be improved by the application of fertilizers; if there be such, I heartily congratulate the owners, and advise them not to sell. Nor do I believe that there are many acres so fertile that they would not produce more Indian corn, more hemp, more cotton, and more of whatever may be their appropriate staple, if judiciously fertilized. If there be farms or fields originally so good that manure would not increase their yield, I am confident that the first half dozen crops will have taken that conceit out of them. Prairies and river bottoms may yield ever so bounteously; but that very luxuriance of growth insures their gradual exhaustion of certain elements of crops, which must needs be replaced or their products will dwindle. Whoever has sold a thousand bushels of grain, or its equivalent in meat, from his farm, has thereby impoverished that farm, unless he has applied something that balances its loss. "I perceive that virtue has gone out of me," observed the Saviour, because the hem of his garment had been touched; and every field that has been cropped might make a similar report whenever its annual loss by abstraction has not been balanced by some kind of fertilizer. The farmer who grows the largest crop is the most merciless exhauster of the soil, unless he balances his annual drafts (as good farmers rarely do) by at least equal reënforcements of the productive capacity of his fields.

Clay as a Fertilizer.

The good farmer begins by inquiring, "Wherein was my soil originally deficient? and of what has it been exhausted by subsequent crops?" I judge that my gravelly hill-sides would reward the application of two hundred loads (or tons) of pure clay per acre, as I think the clay flats which border Lake Champlain would pay for a like application of sand or fine gravel where that material is found in convenient proximity; and yet I know very well that, on at least three-fourths of our country's area, such application would cost far more than it would be worth. Every farmer must act on his knowledge of his soil and its peculiar needs, and not blindly follow the dictum of another. Yet I know few farms which, were they mine, I would not consider enhanced in value by a vigorous application of *some* alkaline substance—lime, salt, ashes, or some one of the cheaper nitrates.

The Use of Ashes and Salt.

I should be very glad to apply one thousand bushels of good house-made, hard-wood ashes to my twenty acres of arable up-land, if I could buy them, delivered, at twenty-five cents per bushel; but they are not to be had. I doubt that there are a hundred acres of warm, dry, gravelly or sandy soil east of the Alleghanies that would not amply reward a similar application. But ashes in quantity are not to be had, since no good farmer sells them, and coal is the chief fuel of cities and villages. The marls of New Jersey I judge fully equal in average value to ashes which have been nearly deprived of their potash, by leaching, but not quite half equal, bushel for bushel, to *un*leached ashes. I judge that average marl is worth ten cents per bushel, where ashes may be had for twenty-five. But marl is found only in a few localities, and a material worth but ten cents per bushel will not bear transportation beyond forty miles by land or 200 by water. Salt is only found or made at a few points, and is too dear for general use as a fertilizer. Where the refuse product of saltworks can be cheaply bought, good farmers will eagerly compete for it, if their lands at all resemble mine. I judge the ton of potash I ordered fifteen years ago from Syracuse, paying $50 and transportation, was the cheapest fertilizer I ever bought. It was so impregnated with salt (from the boiling over of the salt kettles into the ashes) as to be worthless for other than agricultural purposes; but I mixed it with a large pile of muck which I had recently dug, and, six or eight months thereafter, applied the product to a very poor, gravelly hill-side which I had just broken up; and the immediate result was a noble crop of corn. That hill-side has not forgotten the application.

[Ashes are perhaps of less utility as a fertilizer for wheat than for almost any other crop. Hard-wood ashes contain all the elements of plant food except phosphoric acid; but as that acid is particularly important in the formation of the wheat grain, it follows that wheat sown upon land deficient in phosphoric acid would not fill out well, although it might present an abundant and vigorous growth of straw—Ed. Press].

Lime as a Fertilizer.

If I should try to explain how and why lime is a fertilizer, I should probably fail; and I am well assured that liming has in some cases been overdone; yet I think most observers will concur in my statement that *any region which has been limed year after year produces crops of notable excellence.* I cite as examples, Chester and Lancaster counties, Pennsylvania, with Stark and adjacent counties in Ohio. Possibly, results equally gratifying might be secured by applying some other substance; I only *know* that frequently limed lands are generally good lands, as their crops do testify. I heartily wish that the flat clay intervales of Western Vermont could have a fair trial of the virtues of liming. I should expect to see them thereby rendered friable and arable; no longer changing speedily from the semblance of tar to that of brick, but readily plowed and tilled, and yielding liberally of grain as well as grass. I am confident that most farms in our country will pay for liming to the extent of fifty bushels per acre where the cost of quick lime does not exceed ten cents per bushel; and most farmers, by taking, hot from the kiln, the refuse lime that is deemed unfit for building purposes, can obtain it cheaper than that.

A Hint to Experimentors.

I wish some farmer who gives constant personal attention to his work—as I cannot—would make some careful tests of the practical value of alkalies. For instance: the abundance and tenacity of our common sorrel is supposed to indicate an acid condition of the soil; and all who have tried know that sorrel is hard to kill by cultivation. I suggest that whoever is troubled with it should cover two square rods with one bushel of quick lime just after plowing and harrowing this spring; then apply another bushel to *four* square rods adjacent; then make similar applications of ashes to two and four square rods respectively, taking careful notes of the boundaries of each patch, and leaving the rest of the field destitute of either application. I will not anticipate the result; more than one year may be required to evolve it; but I am confident that a few such experiments would supply data whereof I am in need; and there are doubtless others whose ignorance is nearly equal to mine.
—*Horace Greeley.*

Destruction of Forests.—Reports come from New York that a terrible conflagration is raging in the woods in Sullivan, Orange, Madison, and other counties of that State. It is said to extend over a tremendous extent of territory, and the loss is already estimated at $5,000,000. In the night time the spectacle is grand and startling. By the wanton carelessness of some idiot, an irreparable loss is thus inflicted on the country.

The Sutro Tunnel.

The Gold Hill *News* of the 3d inst. has an article in reply to what was stated in a former issue of the PRESS with regard to the Sutro Tunnel. As, however, it takes it for granted that the tunnel would not do any good, while it would merely increase the company's expenses by the amount per ton of ore extracted which is to be paid as royalty to the tunnel company, it only begs the question.

In regard to our remarks upon "very low grade ore worth a few dollars per ton," we have merely to say that such expressions are comparative. We are acquainted with the fact that quite poor ores have been worked for some time at Virginia City, and we opine that still poorer ores will be worked in the future, with better milling processes and such advantages as the tunnel will offer. We are also aware that much low grade ore has been treated at a loss to the miners but a profit to the mills!

We are not inclined, however, to discuss the matter further, being firmly convinced by the evidence before us that the tunnel can be made of much benefit to legitimate operations. And so long as we see that the miners are in favor of the project and believe that the controlling influence of the mines *would be glad to take the tunnel*, could they get control of it, we shall probably hold to our present idea on the subject.

* * *

MEETING OF FISH COMMISSIONERS—A meeting of the Fish Commissioners was held on the 13th inst. Plans for the preservation of our fish and the introduction of new varieties were discussed. A resolution was adopted calling upon the District Attorneys to enforce stringently the laws against the illegal taking of fish, and asking them to give notice of any obstructions in the streams to the passage of the finny tribe. They request from all true fishermen notice of any violation of the laws. We hope that they may meet with general assistance in their labors to prevent the annihilation of fish in our streams.

* * *

THE preliminary survey of the railroad between Denver and Georgetown, Colorado, is completed. The work is to be pushed energetically, we are told. We congratulate our Georgetown friends.

Stockton and Copperopolis Railroad.

California seems determined to remove all grounds for a charge of being behind the age in the matter of railroads. There is unwonted activity just at present in railroad building, and a whole batch of new schemes are on the cards. We have spoken previously of several of our finished roads; we shall treat to-day of a new one—the Stockton and Copperopolis Railroad.

This road was projected as early as 1862, and a company was regularly organized in 1865, and some eleven or twelve miles out of Stockton graded. Owing to monetary depression in California, and more especially to the fall in the price of copper (which so injuriously affected the mines at Copperopolis), the scheme was temporarily abandoned. It is now revived with brighter prospects than ever, and the management are confident of success with the greater value of copper, the high protective tariff, the cheaper labor and the constant agricultural development in the country through which this short line of forty miles passes. Thirty-three miles of the road are through a perfectly level and rich agricultural valley, studded with ranches. Twenty-five miles out of Stockton there are a few steep grades, in no case, however, exceeding ninety feet to the mile. From the Reservoir at Salt Spring Valley to Copperopolis, a distance of eight miles, the grades are again easy, the country being either level or rolling.

The counties either directly benefited or tributary to the line are, San Joaquin, Tuolumne, Calaveras, Stanislaus, Mariposa, Merced, Fresno and Tulare. The agricultural resources of the district are very great; its upper portions, the forest lands, will afford large quantities of lumber and wood; marble of good quality, granite, freestone, lime, coal, iron and manganese ore are all found on or near the line of the railroad. An extensive slate quarry has recently been opened at Copperopolis. But the principal item of profit will, it is thought, be derived from the transportation of copper ore. The mines at Copperopolis, the immense copper ledge, with its two or three hundred claims, will be very directly benefited by the construction of this road. The Copperopolis mines have yielded since 1864 over 80,000 tons of superior ore, while 40,000 tons of low-grade ores lie on the surface, awaiting cheaper means of transportation than that afforded by teams at $8 per ton. The railroad will do it for $3.50. The ore freight at the Union mine, Copperopolis, long averaged 3,000 tons per month (26 working days). During the year 1865, this company paid over $290,000 freight money. Recent processes, notably the Kidwell, and also the lixiviating process tested at the Napoleon mine, have, it is claimed, shown the possibility of making ores no richer than 3 or 4 per cent. pay well. There are several mines, as that at Quail Hill, in which considerable sums of money have been sunk, and which are only awaiting the facilities of railroad transportation to resume working.

The benefits of the line to Stockton will be great, not merely in adding one more line to the net-work of railroads which will some day converge there, but in bringing it directly in connection with the rich agricultural lands of the San Joaquin Valley, Stanislaus, etc., of which it is the commercial depot. Wood costs there $6 to $9 per cord; now it is brought from a considerable distance; it will be reduced at least one-third in price by the difference in the cost of freighting. Stockton is said to have expended over one million dollars in grading and graveling its streets, the larger part of this sum having been spent for the latter item. The railroad, it is affirmed, will save the city hundreds of thousands of dollars in this one matter, and enable the authorities to complete all improvements needed.

The completion of this railroad will reduce the time occupied in a journey to the Big Trees of Calaveras to one day. The traveler of the future will be able to leave San Francisco in the early morning and sit under the shadow of the forest giants the evening of the same day. He will only have about thirty-two miles staging out of the entire distance; and the projectors of the line assert that they will put on an extra line of coaches, and take visitors through from San Francisco at a cost of from $7.50 to $9 a head. Thus one of the grand sights of California, visited last year by 3,000 persons, and to be probably inspected by a much larger number this year, will be within the reach of nearly everybody. At some future time the road may be extended to or near the Mammoth Grove itself.

The earnings of this road for the first year are estimated at $575,000; this estimate being based on the profits of agricultural freights, wood, etc., and only assumes that fifty passengers per diem will travel each way. The profits derived from the transportation of copper ores and other mineral products have not been included in it at all.

The above are some of the principal points urged in favor of the road. The benefits it will confer on the district are, apparently, appreciated by the inhabitants, who are liberally taking stock. The company has a land grant of 256,000 acres, but has no county or State aid, the management being confident of succeeding without such. Contracts have been made and ties bought for the first twenty miles, on which work is already commenced. We may add that the President of the company is Gen. J. C. Sullivan and the chief engineer R. L. Harris, while many other prominent men are interested.

* * *

SUBSTANTIAL ROOFING.—The Warren Felt, Cement and Gravel Roofing, which has been largely used in New York for many years, has proved perfectly satisfactory and durable, so far as we learn, and we know its use is being greatly extended. The proprietors warrant their roofs for some thirteen years. We know of a roof in Massachusetts covered to order by this roofing over nine years ago, that has well stood the test of a cold and hot climate. The proprietorship of this roofing has recently changed from Barnes & New to T. New, who will carry on the business as heretofore at No. 32 John street, New York. We would like to see a branch house established in San Francisco for the Pacific coast for this first-class, durable and economical roofing. We have known Mr. New intimately for many years, and as a gentleman of business qualifications, gentlemanly deportment and sterling habits, we doubt if he has his superior in all Gotham.

* * *

ZERAH COLBURN.—We regret to record the death of this most able engineer and talented writer at Belmont, near Boston. Standing in the foremost rank of his profession, of a most brilliant but wayward character, he has done as much as any other person in improving the management of American railways, and was a man, as has been said, whom the profession could ill afford to lose. Of late years, since 1866, he had the editorial charge of London *Engineering*, and remained in this position until a short time ago, when he returned to America, to die by his own hand.

* * *

THE STOCKTON STREET HILL.—A meeting of property owners interested in the proposed cutting down or tunnelling of Stockton street hill, from Sacramento to Sutter street, was held this week. Not much was accomplished, however, except the appointment of a committee to investigate the matter. There is strong feeling, apparently, both against and in favor of any such measure.

A Genuine Treat.

This (Saturday evening) a real treat will be given in the shape of a concert by the San Francisco Musical Institute. A most delicious programme is presented, consisting of selections from the works of Haydn, Gluck, Mozart and Beethoven. We note with pleasure that, although the Institute is but a few months old, the efforts of the managers have been so successful that the pupils have already become capable of sustaining the vocal portion of the programme.

Laboring quietly and diligently to inculcate in their pupils a true love of genuine music, the managers are to be congratulated on the success they have met with. This success is due not only to their diligence and attention, but also to their excellent method of teaching. From the beginning they give their pupils a correct understanding of what good music is. They teach the principles, and the pupil does not learn to "perform" merely, but to play feelingly and understandingly.

Many of you, dear readers, have an ill-defined aversion to what is termed "classical music." But don't confound classical music with musical (or unmusical) gymnastics. Running up and down the scale and showing off the mechanical agility of the performer, is not producing *music*. Many noted musicians, who visit us, insult us by hopping about and around their instruments, metaphorically speaking, and presenting to us merely what *they* can do, interspersing their performances with rattle-trap pieces, which show they consider us musically to be of most inferior capacity. Would you know what music really is? Come then to such concerts as these—you can undoubtedly get tickets by applying at 109 O'Farrell street—and we assure you that you will find *classical* music is capable of affording as much genuine pleasure, even to those without previous musical education, as "Shoo Fly" and "Pop Goes the Weasel."

A Complimentary Letter.

P. M. COLLEGE, VACAVILLE, May 7, 1870.

MESSRS. DEWEY & CO.:—For several months I have been a reader of your more than interesting journal. In doubt as to its claims, as judged of by a hasty glance when your agent, Mr. Murray, made us a visit some months ago, I concluded, as an experiment, to take it for six months only. The specimen leaves then submitted to me impressed me favorably, and encouraged me to make the trial, especially as I was pleased to indulge the hope that I should find it to be worthy of the great industrial department embraced within its scope—a field always interesting to me.

I am happy to say that my hopes are more than realized in the numbers that have come to me.

It is indeed gratifying to me to be able to say that on the Pacific coast we have a first-class journal representing the leading industries of the country. Less than three years ago I emigrated from the old States, where I had access to the best journals published on the Continent and also the reprint of the best published in Europe, and I do not hesitate to say that the SCIENTIFIC PRESS need not be ashamed to show itself beside the best of them.

Indeed, in its own sphere, I regard it the peer of any of them now issued from the Amcrican press.

During my whole lifetime, since early manhood, I have held a place among the public educators of the country, yet always interested in agricultural pursuits incidentally. In this relation I have given special attention to manipulated fertilizers and to the most economical modes of tillage, and that, too, with some marked results of personal experience, some of which I may find leisure to communicate at a future time. Quartz mining, too, has formed an episode in my history, owing to vicissitudes of health. As a matter of course, then, I find congenial and interesting topics ventilated in the PRESS.

Consider me in as a fixture on your list of subscribers, and accept my thanks for the pleasure which your journal has already afforded me. The healthy tone of your paper on theistic subjects is also refreshing in this age of heresy and demoralization.

I have some practical matters, in the shape of mechanical improvements, which I will submit at an early day. Most respectfully,

J. R. THOMAS,
President P. M. College.

[We shall be pleased to receive the promised articles, believing they will be of interest to our readers.—EDS. PRESS.]

* * *

W. H. MURRAY, traveling agent for the Scientific Press, favored us with a call this week. He has visited the Battle Mountain mines, and expresses himself as being highly pleased with the prospects in that district. He intends to visit the several mining districts along the railroad, reports of which will appear in the Press. Every miner should subscribe for the Press, a large portion of which is devoted to mining interests. It is published by Dewey & Co., in San Francisco. Terms, $4 per year, in advance.—*Humboldt Register, May 7th.*

The Grand Hotel.

That it requires a peculiar talent, and one of a high order, to be a first-class landlord is so universally admitted that no phrase is, or was some time ago, more common, when speaking of the qualities of a person not quite up to the desired mark, than, "he's a good fellow, but can't keep a hotel."

No such charge of incapacity has ever been brought against Messrs. Johnson & Co., the late popular hosts of the Lick House, and the present landlords of the Grand Hotel, whose recent completion has set San Francisco all agog, and has drawn a crowd of guests. Nay, we are wrong. It is the uniform courtesy and attention to the comfort of the guests on the part of the host, which has filled the house. San Francisco has long been proud of her hotel accommodations; she is still prouder now.

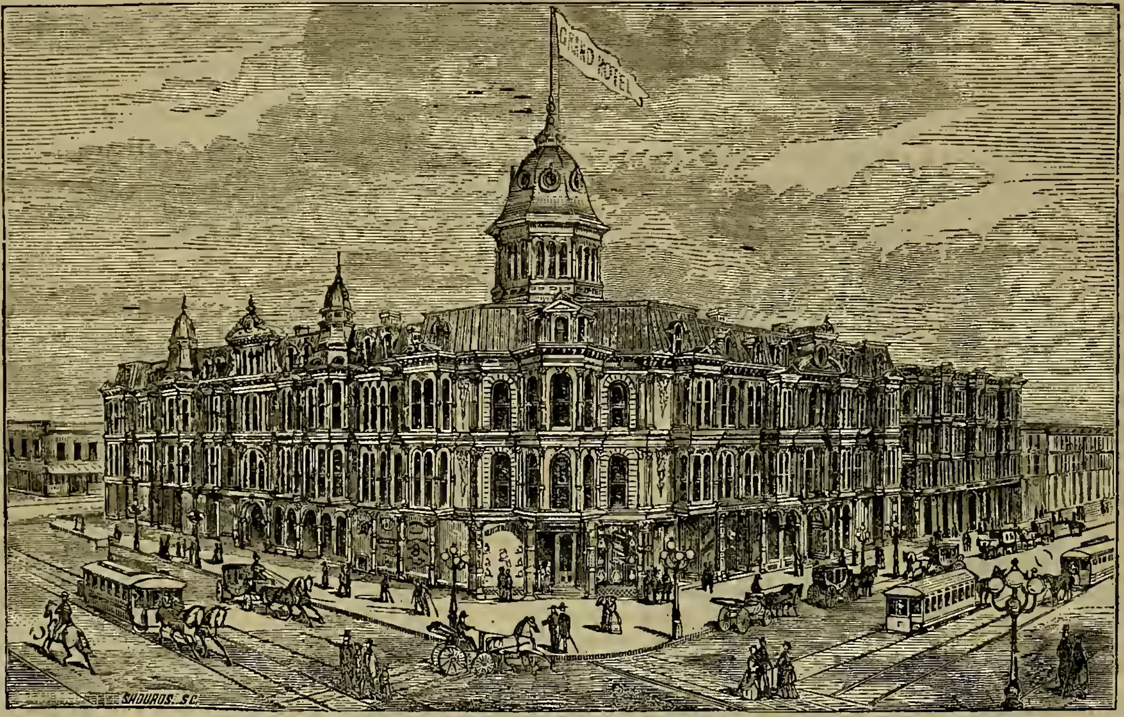
We give our readers to-day an illustration of our "Grand Hotel," with a condensed description of some of the principal points, acknowledging indebtedness therefor to the kindness of the able and energetic *News Letter*. The point of view is one diagonally opposite the corner of Market and Montgomery streets. The style of decoration is, as the *News Letter* remarks, elaborately ornate, affording a cheerful subject for that difference of taste which, not being a matter of argument, admits unlimited disputation. The main building covers the square bounded by Market, Second, Stevenson and New Montgomery streets, and the second building, on the other side of Stevenson street, is connected with this by a spacious gallery or corridor. The Montgomery street front is 335 feet long; Market street front, 205 feet. The hotel has three full stories and a fourth in the Mansard roof, from which one gets a full view of our beautiful bay. The plan of the hotel is that of a structure surrounding a central court, and is so arranged that there is not a room upon which the direct rays of the sun do not fall during the day; a most important point, especially in this climate. The central court has a glass roof and forms a spacious and lofty ball room. The outside rooms are arranged in suites, of a parlor with one, two or three bed rooms, bath room and water closet. The furniture is most luxurious. The dining room is a magnificent apartment of great size, lighted on two sides by windows, and by night by a series of superb chandeliers and side lights, while huge mirrors upon the walls multiply its apparent size to an unlimited extent. Adjoining are breakfast rooms, where also will be served the meals of the children with their nurses and other servants.

In the rear are the pantries, sculleries, and *such* a kitchen! Immensely spacious, along one entire side run the French "ranges," with a cooking capacity for a thousand guests, and capable, therefore, of always providing meals hot and fresh. Adjacent to the kitchen is the butcher shop. The laundry and the baker's department, with the store rooms, are on the lower floor. The office is situated at the Montgomery street main entrance; adjoining is the bar room, and in the basement story, entering from it, is the barber shop, bath rooms and billiard saloon.

The ladies' parlors, on the first floor, are richly furnished, of suitable size and most comfortable in appearance. The gas fixtures are exceedingly neat and of a general uniform character throughout. Upon every floor, along the corridors, a few yards apart, are coils of hose, the water constantly laid on, and available at any instant. The halls and corridors are very spacious, and the wide stairways, with their heavy carved balustrades, of easy ascent, reflect great credit on the builders, Messrs. Hibberd, Sanborn & Co., of the South Point Mills, Berry street. The hotel contains about 400 rooms, and will accommodate some 600 guests.

The hotel is a complete frame building, surrounded by brick walls, and so constructed that there is not the slightest danger to be apprehended from any earthquake shock. The severest one could only throw the brick walls *outwards*, leaving the skeleton standing intact with its roof and floors unmoved. Among others connected with the construction of the hotel, we must not forget the metal roofers, Conlin & Roberts, 749 Mission street, who, among other things, built the handsome galvanized iron chimney tops and other iron work.

For further details we have no room. We can merely say to travelers, come and try for yourselves. But if you can find better accommodations or more courteous and kinder hosts than Mr. Johnson and his associates, we should like to know of it.



THE GRAND HOTEL OF SAN FRANCISCO.

* * *

CHANGEABLE WEATHER.—The recent hot days of the 6th, 7th and 8th inst., following close upon a cold dry spell of weather, had a bad effect upon grain fields just headed out, injuring them so that the grain will not fill out well. The strawberry fields also suffered severely, where not thoroughly irrigated. Many plants were checked in growth and young fruit blighted. Last night, the 16th, quite a severe frost nipped the tops of potatoes, squashes and mellons, vines and corn. The high and drying winds through the day are also severe, and keep young plants backward in growth. Nevertheless, where not subject to the severe drouth, crops look promising this season. S. H. HERRING.

San José, May 17th, 1870.

* * *

BILLIARDS.—The billard tournament has come to an end. Messrs. Little and Mott, having each gained four games and lost two, on Tuesday played a deciding game, in which Mr. Little was victorious, and hence holds the silver cue and the title of champion of the Pacific coast.

* * *

C. C. BATEMAN has been appointed superintendent of the Gould and Curry mine, and entered upon his duties on the 14th instant.

Patents and Inventions.

A Full List of Patents Issued to Pacific Coast Inventors.

[FROM OFFICIAL REPORTS TO DEWEY & CO., U. S. AND FOREIGN PATENT AGENTS, AND PUBLISHERS OF THE SCIENTIFIC PRESS.]

FOR THE WEEK ENDING MAY 10TH.

PENCIL SHARPENER.—Hubert Burgess, Oakland, Cal.

GANG PLOW.—Peter H. Flansburgh, Haywards, Cal.

SELF DISCHARGING PULVERIZING BARREL. Almarin B. Paul, San Francisco.

PRESERVING AND HARDENING STONE, BRICK, ETC.—Elmor J. Salisbury, San Francisco, Cal., assignor to himself and George A. Brush, same place.

APPARATUS FOR SAVING GOLD.—Charles Schofield, Kernville, Cal.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & Co., in the shortest time possible (by telegraph or otherwise), at the lowest rates. All patent business for Pacific coast inventors transacted with greater security and in much less time than by any other agency.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co's Scientific Press American and Foreign Patent Agency, the following are worthy of mention:

APPARATUS FOR SAVING GOLD.—C. Schofield, Kernville, Cal.—This relates to an improved apparatus to be attached to stamp-batteries and through which the ore pulp is passed, in order to separate the valuable portion from the gangue or refuse matter with which it is mixed when it comes from the batteries. It consists of a tank or box divided up into two compartments. At one end of each compartment is placed a hopper-shaped box, which is provided with a false bottom of perforated sheet metal. Water is introduced into the box below the false bottom, and rises through the perforated sheet and thus carries the lighter particles of the pulp, which is led in from above, over into the next similar box, while the heavy particles of metal or amalgam fall to the bottom. The holes in the false bottom of the first box are made larger than those in the second, as the larger and heavier particles are caught in the first. The number of boxes may be increased according to circumstances. In connection with these tanks are sluices with adjustable gates which lead to lower tanks. These are so arranged that, together with the boxes, the pulp is worked over and the sulphurets are concentrated. It is a simple contrivance, which can easily be put up, and which will undoubtedly work well when there is a sufficiency of water and a decent amount of care and attention is given.

PENCIL SHARPENER.—H. Burgess, Oakland, Cal.—To those who write much with the lead pencil, the frequent necessary sharpening of the article is really quite an item, consuming, as it does, considerable time, and being so likely to dirty the fingers. Hence it is that several devices have been invented for the purpose of rendering this work easier and cleaner. The latest and simplest one which we have seen is the one now to be spoken of. This consists of a cylinder, or other suitably shaped block of wood or metal, which is cut beveling on one side. This block or cylinder is perforated longitudinally with a hole, through which the pencil is thrust. A loosely revolving spring is arranged about the hole to clasp the pencil and allow it to revolve inside the block. A knife is used to sharpen the pencil, the bevel of the block guiding it in cutting the wood and sharpening the points. The whole device is exceedingly simple and very cheap.

NEEDLE.—J. W. Donaldson and D. Sheets, Suisun, Cal.—There are quite a number of needles in the market by which the threading is intended to be made easy. This device goes still further. Its chief novelty consists in constructing the end of the finger, or free side of the eye, with an enlargement made beveling each way from its highest point. It can thus be threaded by pressing the bight against the outside, as in the other needles lately patented. But, moreover, the bevel on the inside of the eye permits the thread to be withdrawn with equal ease, the object of this being to free the needle from it, when it is too short for use, without stopping to cut the twine, this being especially necessary in sewing sacks for a threshing machine. While at work there is no danger of the thread slipping out, as the tendency is to keep it at the upper end of the eye.

PRESERVING AND HARDENING STONE, BRICK, ETC.—E. J. Salisbury, San Francisco. This invention has for its object improvements in preseving and hardening building materials. By means of it, it is claimed, bricks or other porous material can be rendered equally durable with the most solid material. It is getting to be quite a matter of public interest now-a-days to know how buildings can be constructed in the cheapest manner, and hence of inferior stuff, so as to enable the poorest classes to have decent dwellings. This invention is a step towards making this a possibility.

* * *

SHEARING SPRING LAMBS—COTSWOLD SHEEP.—One hundred and seventy-six bales (42,000 pounds) of wool were received in this city, on Friday last, from the Buckley Brothers, of Snellings, Merced county. Of this amount, thirty bales (7,000 pounds) were from graded Cotswolds, eleven of which consisted of fleeces taken from spring lambs dropped in February and March last. Thirteen hundred of these fleeces averaged two and a half pounds each, the heaviest going as high as five pounds. This is said to be the first shearing of spring lambs on record, and affords a most remarkable evidence of the capacity of the climate of California in this important department of stock-growing. The Buckley Bros. have a stock of about 4,000 graded sheep. We shall take an early occasion to make a more extended reference to the operations of this firm.

* * *

PATENTS ON THE PACIFIC COAST.—To those of our friends who desire to keep posted upon inventions upon the Pacific coast we say, subscribe for the SCIENTIFIC PRESS, published by Dewey & Co., San Francisco, Cal., at $4 per year. The opening of the railway across the continent has given to all patents a much higher value in that portion of our country known as the Pacific slope, and all interested will find the paper above alluded to a valuable reference.—*Mechanic and Inventor Detroit, Michigan.*

Manufacturers and have constantly on hand
SPORTING,
MINING,
And BLASTING
POWDER,

Of SUPERIOR QUALITY, FRESH FROM THE MILLS. It being constantly received and transported into the interior, is delivered to the consumer within a few days of the time of its manufacture, and is in every way superior to any other Powder in Market.

We have been awarded successively

Three Gold Medals

By the MECHANICS' INSTITUTE and the STATE AGRICULTURAL SOCIETY for the superiority of our products over all others.

We also call attention to our

HERCULES POWDER,

Which combines all the force of other strong explosives now in use, and the lifting force of the best blasting powder, thus making it vastly superior to any other compound now in use.

A circular containing a full description of this Powder can be obtained on application to our Office.

16v20-3m

By authority of a Special Act of the Legislature of the State of California, approved February 19, 1870, the Trustees of the Mercantile Library Association have the pleasure to announce that a

GRAND GIFT CONCERT

IN AID OF THE

Mercantile Library Association

—WILL BE GIVEN AT THE—

MECHANICS' PAVILION,

SAN FRANCISCO, CAL.,

THURSDAY, SEPTEMBER 1st, 1870,

Under the direction of Distinguished Artists, and embracing selections from the most Favorite Masters. Programme of Concert to be hereafter announced.

Tickets of Admission, $5 Each, Gold Coin.

Each Ticket consists of Five Coupons. The holder of a whole Ticket, or five coupons, will be entitled to admission to the Concert, and to the whole amount of the Gift awarded to it. The holder of each coupon will be entitled to admission to the Concert, and to one-fifth of any gift that may be awarded to such ticket.

To provide funds for this MAGNIFICENT ENTERTAINMENT,

200,000 Tickets will be Sold

At Five Dollars Each, Gold Coin.

TREASURER.......THE BANK OF CALIFORNIA.

During the Entertainment, the sum of

$500,000, U. S. Gold Coin,

Will be returned to the holders of tickets by the distribution, by chance, of the following

GIFTS:

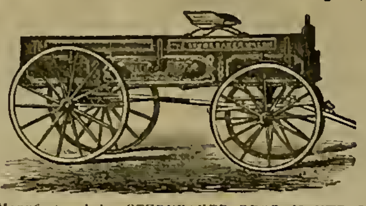
☞ NOTICE TO MECHANICS.—A premium of $500 will be given for the best model of two Wheels of Glass and Iron, for this distribution. The Trustees reserve the right to reject any and all models.

POST OFFICE BOX, 1089.

The Celebrated Studebaker Wagon,



Manufactured by STUDEBAKER BROS. MANUFACTURING CO., South Bend, Indiana. WAGON DEALERS, there are nine reasons why you should buy the above Wagon:

FIRST.—They are made of the best selected INDIANA TIMBER, thoroughly seasoned under cover.

SECOND.—They are made by experienced mechanics.

THIRD.—The lightest running and most durable Wagon in the market.

FOURTH.—Their Thimble Skeins never break, while all others do.

FIFTH.—Most uniform and best proportioned Wagon in the market; any part of one will fit another, while other makes will not.

SIXTH.—The only Wagon in which the SLOPE SHOULDER SPOKE is used; hence they have the best Wheel, which is actually the foundation of the Wagon, and should be carefully examined by persons buying.

SEVENTH.—They are sold only by responsible parties, and every Wagon is warranted to give entire satisfaction.

EIGHTH.—Because Teamsters will tell you they are the best Wagons, for all purposes, on the road.

NINTH.—Last, but not least, Studebaker Brothers are practical men, attend to their business personally, and do not entrust it entirely to foremen, as is generally the case in large factories; hence the superiority of their work over all others. Sold by

SAPOINE

FRAGRANT SAPOINE FOR THE TEETH

THE GREAT MEDICAL DISCOVERY!

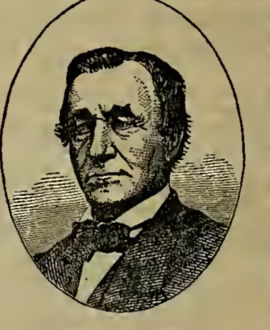
Dr. J. Walker's California

VINEGAR BITTERS.

More than 500,000 Persons

Bear testimony to their wonderful Curative Effects.

WHAT ARE THEY!



They are not a vile

FANCY DRINK,

Made of Poor Rum, Whiskey, Proof Spirits, and Refuse Liquor, doctored, spiced, and sweetened to please the taste, called "Tonics," "Appetizers," "Restorers," etc., that lead the tippler on to drunkenness and ruin, but are a true Medicine, made from the native roots and herbs of California, FREE FROM ALL ALCOHOLIC STIMULANTS. They are the GREAT BLOOD-PURIFIER AND LIFE-GIVING PRINCIPLE, a perfect Renovator and Invigorator of the System, carrying off all poisonous matter, and restoring the blood to a healthy condition No person can take these Bitters according to directions and remain long unwell.

They are a gentle Purgative as well as a Tonic, possessing, also, the peculiar merit of acting as a powerful agent in relieving Congestion or Inflammation of the Liver, and all the Visceral Organs. In Bilious, Remittent and Intermittent Fevers, these Bitters have no equal. For full directions, read carefully the circular around each bottle, printed in four languages—English, German, French and Spanish.

One Hundred Dollars will be given for an incurable case, provided the bones are not destroyed by mineral poisons or other means, and the vital organs wasted beyond the point of repair.

For Inflammatory and Chronic Rheumatism, and Gout, Dyspepsia or Indigestion, Bilious, Remittent and Intermittent Fevers, Diseases of the Blood, Liver, Kidneys and Bladder, these Bitters have been most successful. Such Diseases are caused by Vitiated Blood, which is generally produced by derangement of the Digestive Organs.

Cleanse the Vitiated Blood whenever you find its impurities bursting through the skin in Pimples, Eruptions or Sores; cleanse it when you find it obstructed and sluggish in the veins; cleanse it when it is foul, and your feelings will tell you when. Keep the Blood pure and the health of the system will follow.

J. WALKER, Proprietor.

FOR FEMALE COMPLAINTS, whether in young or old, married or single, at the dawn of womanhood or the turn of life, these Tonic Bitters display so decided an influence that a marked improvement is soon perceptible in the health of the patient. PIN TAPE, and other WORMS, lurking in the system of so many thousands, are effectually destroyed and removed. ☞ SEND FOR A CIRCULAR.☜

Independence Quartz M. Co.—May 11th: Trustees: C. J. Klein (President), F. G. Smith (Vice-Presidentand Secretary) and Alfred Wood (Superinteudent).

Ice Contest.—On the 5th inst. the agent of the Summit Valley and of the Little Grass Valley Ice companies held a trial of ice of their respective manufactures at Marysville. Two large pieces, of 131 ponnds each, were exposed to the sun, to determine which would last the longer. Tho contest commenced at ten o'clock in the morning. The Summit company's ice withstood the effect of the heat much the better during the day, but the Grnss Valley ice eventually came out ahead, lasting four hours and fifty minutes longer than the other. As, however, the pieces were of differeut shapes, and we aro not nssured that equal protection against the wind—a most important agency—was given, we do not feel quite satisfied. Let us have another test where every procaution for insuring the same circumstances for both kinds may be hnd. These may have been taken in the present instance, but the account does not state it.

Continental Life Insurance Co., 302 Montgomery street, corner of Pine.

Merchants' and Bankers' Almanac for 1870.—It is seldom that we find snch a work as this gotten up in such style and with such marks of good taste. Handsomely bound, well printed and with choice engrnvings, it forms a most attractive-looking volume, while its coutents include very much of value and interest to those among whom it is intended to circulate. Besides its full list of banks and bankers in the United States and elsewhere, it contains the monthly prices of various commodities, as grain, flonr, wool, etc., etc., for forty-three years; the daily price of gold from January, 1864, to December, 1869; valuable articles on the parities of exchange, the progress of railroads in the United States from 1835 to 1869, the cotton crop, statistics of immigration, the public debt, and much other matter of great value for reference. It is published at the office of the Bnukers' Magazine and Statistical Register, 41 Pine street, New York.

To Advertisers.

After January 1st, 1870, the latest hour for receiving mining and other advertisements for the M. and S. Press will be during Thursday evening, as our paper will be printed for the interior mails on Friday morning.

A Civil Engineer

Of thirteen years standing and highest Eastern, Sonth American and Pacific coast references, tenders his services at moderate rates. Can present attractive inducements to capitalists. Address W. S. C., Box 1,036, San Francisco. 20v20-1m

☞ Maravilla Cocoa.—*For Breakfast.*—The *Globe* says: "Various importers and manufacturers have attempted to attain a reputation for their prepared Cocoas, but we doubt whether any thorough success has been achieved until Messrs. Taylor Brothers discovered the extraordinary qualities of 'Maravilla' Cocoa. Adapting their perfect system of preparation to this finest of all species of the Theobroma they have produced an article which supersedes every other Cocoa in the market. Entire solubility, a delicate aroma, and a rare concentration of the purest clements of nutrition, distinguish the Maravilla Cocoa above all others. For homœpaths and invalids we could not recommend a more agreeable or valuable beverage." Sold in packets only by all Grocers, of whom also may be had Taylor Brothers Original Homœopathic Cocoa and Soluble Chocolate. Steam Mills—Brick Lane, London. 5v20-1y

To Miners, Millmen and Metallurgists. Kustel's new work on the Concentration of all kinds of Ores, and the Chlorination Process, for Gold-bearing Sulphurets, Arseniurets, and Gold and Silver Ores generally, is the best and most complete work issued. It contains 120 diagrams, illustrating machinery, etc., which alone are of the greatest value. Price, $7.50, postage paid. Pnblished by Dewey & Co., publishers of the Scientific Press, San Francisco.

There is no light equal to the Portable Gas Light, for Families or Business places, in town or country; at one-fourth the cost of coal gas, and cheaper than coal oil. The Lamps and County Rights are for sale at P. J. PHILLIPS & CO., 550 Market street. No trimming wicks or breaking chimneys. Everybody should see and have them. 19v20

Muller's Brazilian Spectacles are just the thing for people fond of reading whose eyesight is beginning to fail. His great skill as an optician enables him to suit all conditions of sight. It is Muller who supplies the city with opera glasses. *

We call attention to the new portable gas burner—the only one that can be regulated to any size, flame, and burn without smoke or smell. Equal to any gas at one-fourth the cost. P. J. Philips & Co., 650 Market street, have county rights for sale for this valuable invention; also lamps for sale. No one should be without them who wants a good, cheap and safe light. 21v20-4w

Co-Operative Union Store.—This is becoming one of the most useful Institutions in the city, and the Mechanic and Laboring Man fully appreciate it. They are now enabled to buy their Groceries and Provisions 20 per cent. cheaper than ever before, and the very best articles in the market. The store is located at 115 Sutter street, Lick House Block

Business Fortunes are often made easily, quickly and legitimately by Patent Rights. We advise both sellers and purchasers to patronize reliable agents only. Weister & Co., patent brokers, No. 314 Bush street, San Francisco, are one of the most honest, reliable firms in the United States. *

To Farmers.—Stevens & Bro's Egg Boxes, holding 30 dozen, supplied free of charge, by John Gray & Co., No. 210 Clay street, San Francisco, to all customers. The eggs are kept cool and free from moisture and mould, are in no danger of being broken, and require no recounting. 20v20-3m

Mason's Bread of Life, for Dyspeptics, Coughs, Colds, Asthma, Catarrh, Hoarseness, Bronchitis aud Sore Throat. Price, 25 cents per box. These lozenges are free from all dangerous properties. Compounded and put up by Dr. J. H. Mason, 750 Howard st. 16v20-3m

Photography.—For Cabinet Photographs, or Enameled Cards, of the very best quality, you must go to the NEW YORK GALLERY, Nos. 25 and 27 Third street, San Francisco. Every picture warranted to give satisfaction.
10v18 6m R. F. Howland.

Thomas O'Neil Ornamental Glass Cutter, No. 10 Stevenson street, up stairs. Stained, Ground and Ornamental Cut Glass to order on reasonable terms. 14v20

Microscopes for Scientific Investigation aud Educational Purposes. Price list sent free. T. H. McAllister, Optician, 49 Nassau street, New York. 15v20-3m

Drs. Martinache & Smith, Oculists and Aurists, 313 Bush street, between Montgomery and Kearny. Hours for consultation, 12 to 3. 16v20-3m

F. Gruber, Naturalist, No. 626 California street, between Kearny and Dupont, San Francisco. Birds and auimals stuffed to order, 13v20-3m

Block Tin and Solder Wire, broom wire, piano covering wire, etc., manufactured by Joshua Gray, 437 Brannan street. 24v19-3m

A Valuable Book for Inventors and Artisans.—Dewey & Co., publishers of the Scientific Press and Patent Agents, have just issued a neat little volume of over five hundred well executed cuts of the principal mechanical movements known. These useful representations of the various appliances of power are printed side by side with explanatory notes, which makes the subject clear to every reader. Such a book should be in the hands of every mechanic, and form part of every public school library. It is a handy book, and cheap enough for every farm, shop and factory. Sent to any address from the Scientific Press office, postpaid, for $1.—*New Age.*

CRANDALL'S

PATENT SPRING BED.

This invaluable Spiral Spring Bed combines all the good without any of the bad features of the common spring mattrass. It consists of a framework of springs resting on a bed of stronger springs, thus giving it nearly double the elasticity of any other bed. The springs are self-supporting, each pair being independent of the others, and consequently the tendency to sag or incline toward the middle is avoided. Unlike other spring beds, they require no upholstering, and, of course, afford no harbor for fleas or dust. The medical faculty have pronounced it the best Bed in use. It commends itself to those who have examined and used it. They invariably pronounce Crandall's Patent the best Spring Bed ever offered to the public.

These Beds are on exhibition and for sale at the Cabinet Warerooms of

JOHNSON & BEST,

No. 413 PINE STREET, RUSS BLOCK,

Between Montgomery and Kearny. Also at

639 Market Street, near New Montgomery.

Beds guaranteed to give satisfaction

Or the money will be refunded.

Refer, by permission, to the following, among the many using our Beds, who are willing to testify to their superiority:

SAN FRANCISCO AND VICINITY—J. B. Pierce, Esq., residence Sixteenth and Capp streets, office 315 California street; J. H. Rogers, Esq., residence Oakland Point, office 16, 17 and 18 California Market; W. Zelheer, Esq., residence 613 Geary street; James Dexter, Esq., office 430 Sansome street; John A. Roth, Esq., residence 106 Silver street. James Counor, Esq., Alameda.

N. B.—Responsible persons can have one on trial.

Sheffield Scientific School

Of Yale College, New Haven, Conn.

This department of Yale College, instituted in 1840, and endowed with the National Land Grant in 1866, furnishes advanced instruction in the various branches of Mathematical, Physical, and Natural Science.

The School is under the direction of the President of the College, a Board of thirteen Professors in differe spacial ties, and six assistant instructors.

Regular courses of study, leading to the degree of Bachelor of Philosophy, conferred by Yale College, are arranged as follows: 1—CHEMISTRY AND MINERALOGY. 2—CIVIL ENGINEERING. 3—MECHANICAL ENGINEERING. 4—MINING ENGINEERING AND METALLURGY. 5—AGRICULTURE. 6—NATURAL HISTORY AND GEOLOGY. and 7—SELECT COURSE.

Advanced students are also admitted to optional courses, and if already College graduates, are received as candidates for the degree of Doctor of Philosophy.

Tuition, $125 per year of forty weeks.

The Libraries, Museums, Laboratories and Apparatus accessible to students, are varied and extensive.

For copies of the Annual Circular and Report, letters may be addressed to the "Secretary of the Sheffield Scientific School." New Haven, Conn. v16-1y16p

ECONOMY AND CLEANLINESS

Are to be found in the use of the

PATENT SPRING BED.

They are the cheapest and best in the market. Manufactory on Twelfth street, bet. C and D, SACRAMENTO. Caveat filed Aug. 9, 1869. [15v20] G. B. DEAN.

THE large majority of United States and Foreign Patents granted to inventors on the Pacific coast during the past few years, have been obtained through the agency of DEWEY & Co., publishers of the SCIENTIFIC PRESS. Established in the year 1860, we have an extensive patent library, with full record of cases on this coast, and can give the best and most reliable advice as to the patentability of new inventions.

LEA & PERRINS'
CELEBRATED

Worcestershire Sauce.

CAUTION AGAINST FRAUD.

Declared by Connoisseurs to be the only good SAUCE. The success of this most delicious and unrivalled Condiment having caused certain dealers to apply the name "Worcestershire Sauce" to their own inferior compounds, the public is hereby informed that the only way to secure the genuine is to ASK FOR LEA & PERRINS' SAUCE, and see that their names are upon the wrapper, labels, stopper and bottle.

Some of the foreign markets having been supplied with a spurious Worcestershire Sauce, upon the wrapper and labels of which the names of Lea and Perrins have been forged, L. and P. give notice that they have furnished their correspondents with power of attorney to take instant proceedings against manufacturers and vendors of such, or any other imitations by which their right may be infringed.

Ask for LEA & PERRINS' Sauce and see name on wrapper, label, bottle and stopper.

Wholesale and for export by the Proprietors, Worcester; Crosse and Blackwell, London, &c., &c., and by Grocers and Oilmen universally. Agents, CROSS & CO., San Francisco. 1v20-1yeow

Crandall's Patent Spring Bed.

Manufactory, corner Front and M streets, SACRAMENTO COOLEY, HENRY & CO., Proprietors. These Spring Beds, wherever known, are universally acknowledged to be superior to any other in use. They are light, durable and elastic, and present no harborage for bugs or any other kind of vermin, thus being free from the objections so often urged against the ordinary spring beds. ☞ Orders received at our manufactory, or at our agency in San Francisco. 7v20-3m

---

WILSON'S

STEAM STAMP MILL.

This mill has now been in use, enduring the severest tests, for the last two years, during which time it has been introduced into most every mining State and Territory in the Union, and is everywhere received with great and increasing favor, having been in every instance eminently successful, and proved to be the cheapest in first cost, and the most economical in working, and most durable of all stamp mills.

It crushes from **25 to 40 tons** of rock through the ordinary size screens in twenty-four hours, and only requires from two to two and a half cords of wood per day (24 hours). It can be put in operation in a few days after it reaches the mines. The mill is complete when it leaves the shop, and weighs about 6,000 pounds. To be fully appreciated it should be seen in practical operation. Even the most skeptical in improvements of crushing machinery agree to its practicability; and mines that will not pay to work with the ordinary stamp mill can be worked at a profit with the Wilson Steam Stamp Mill. One of these mills can be seen in operation at the Pacific Iron Works, First street. Address,

FURMAN R. WILSON,
San Francisco.

NOTICE.—The improved steam stamp mill that was so complete a failure at Silver City, Nevada, was **NOT** one of the Wilson Mills, but was a **base and fruitless attempt to evade the Wilson Patents,** the Wilson Mill never having failed to give unbounded satisfaction in every particular, so much so that unprincipled parties are using the reputation of the Wilson Mill to foist their own fruitless experiments on the public.

FURMAN R. WILSON.

Greatest Discovery Ever Made.

MR. J. W. MAC, while a resident in New Zealand, was so afflicted with the RHEUMATISM, thst for years he was completely crippled and unahle to attend to business. The symptoms were of the worst type—knees painful and swollen, with sinews contracted; shoulder, arm and hsnd rendered useless, and accompanied with continued excruciating psin. While in this state of suffering, he got acquainted with a native of the country, who applied to the parts affected a composition spread on coarse canvas, the properties of which wers so wonderful that in a short time all the pain left him, the swelling disappeared, his sinews relieved, and he was able to resume his usnal avocations. So effectusl has been tho remedy, that to this day he has enjoyed perfect health; without the slightest return of his former complaint. Knowing the grest blessing such a remedy would he to those afflicted with this painful disease, he with grest difficnlty and expense obtained the secret of prepsring the Plaster; and during the many years MR. MAC has applied thsse Plasters in New Zealand, Tssmania, New South Wales, and this city, their effect has been marvelous, giving to the most painful and long-standing cases sure and certain relief. The most incredulous will he convinced hy referring to these persons: B. W. Owens, 405 Front street; F. B. Alderson, Travoling Agent for Dewey & Co., 414 Clay street; James Flynn, 519 Mission street: Michasl Gorman, No. 6 Front street; Mrs. W. S Wright—late of Gilmore House—518 Folsom street, now agent at Virginia City; E. Shenley, corner Montgomery and Filbert streets; W. M. McLeod, Depository merican Tract Society, 557 Market street, and a host of others, who all bear testimony to the unparalleled healing powers of J. W. MAC'S (rightly termed Magic) Plasters, for the curs of Rheumatism, Gout, Weak Loins, Tender Feet and Neuralgia. J. W. MAC may be consulted at his office, rooms Nos. 34, 35 and 36, 128 Kearny street, San Francisco, between the hours of 9 to 12 a. m., 2 to 4 p. m. and 7 to 9 p. m.

18v20-3m

USE

DR. S. GIRARD SMITH'S
ARAMIRACULAS

—FOR—

RHEUMATISM, GOUT AND NEURALGIA

CURES CUARANTEED.

Has cured Thousands. Has never heen known One hottle will relieve you.

OFFICE, No. 121 POST STREET

Agents Wanted in every City and Town.—Terms Liberal.

Dr. S. Girard Smith, 621 *Kearny street.*—Dear Sir It would be hard for me to say how much I thank you for the benefit your ARAMIRACULAS has conferred on me in curing my RHEUMATISM. I was confined to my hed when I first commenced to take your medicine, and after using ONE BOTTLE I am now able to work as well as before. If you know anything ahout having that afflictive complaint, you must know how good it is to be cured. I will state to those who may not believe in your medicine, that they can be convinced by rsferring them to me. Very respectfully, yours,

ENON HARRIS,
Everard's Auction Rooms, 527 Kearry street.

Statement of an old and well-known Physician who has practiced extensively in Europe and America.

We must admit that the msny systems of medicine by which we have attempted to heal the human body, snd rid it of disease, from ths science of ALLOPATHY down to HYDROPATHY, how little they have succeeded, tims has abundantly shown hy their number of failures. In the cure of RHEUMATISM, GOUT and NEURALGIA, Dr. S. Girard Smith has laid aside the old way and adopted a system, so simple, thst I must sdmit, is so natural and direct, that it recommends itself to all who are suffering with the sbove diseases. And it challenges and defies all the old methods of treatment. Although I hsve heen educated through a regular course, and graduated in Europo, I must acknowledge the right, and also give due credit for personal benefit received by the new system as practiced by DR. S. GIRARD SMITH, which induces ms to bear this testimony to its merits, for ths benefit of suffering humanity.

A. M. HOFFMAN, M. D.,
11v20-3m New Orleans.

Ayer's

Hair Vigor,

For restoring Gray Hair to its natural Vitality and Color.

A dressing which is at once agreeable, healthy, and effectual for preserving the hair. *Faded or gray hair is soon restored to its original color with the gloss and freshness of youth.* Thin hair is thickened, falling hair checked, and baldness often, though not always, cured by its use. Nothing can restore the hair where the follicles are destroyed, or the glands atrophied and decayed. But such as remain can be saved for usefulness by this application. Instead of fouling the hair with a pasty sediment, it will keep it clean and vigorous. Its occasional use will prevent the hair from turning gray or falling off, and consequently prevent baldness. Free from those deleterious substances which make some preparations dangerous and injurious to the hair, the Vigor can only benefit but not harm it. If wanted merely for a

HAIR DRESSING,

nothing else can be found so desirable. Containing neither oil nor dye, it does not soil white cambric, and yet lasts long on the hair, giving it a rich glossy lustre and a grateful perfume.

Prepared by Dr. J. C. Ayer & Co.,

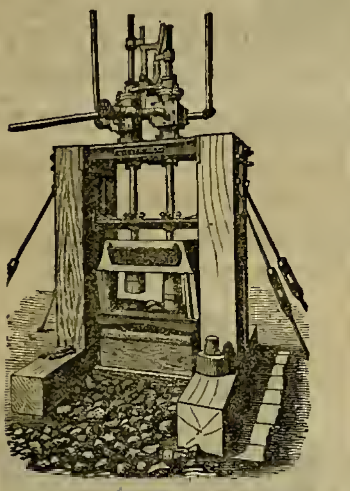
Machinery.

THE WILSON

Patent Steam Stamp Mill.



This extraordinary Mill, now so justly popular in the East, is now offered to the miners of the Pacific Coast. Having been in operation now for about eighteen months, the Company feel confident that the

WILSON STEAM STAMP MILL,

For Durability, Efficiency,

AND ECONOMY OF WORKING,

HAS NO EQUAL.

The Wilson Steam Stamp Mill is the only Steam Mill that has had the severe ordeal of practical working, and proved itself eminently successful. It is now in operation in several of the Eastern States and Territories, and gaining an envious popularity. The whole machine is so simple as to be readily understood by the most ordinary minds. In fact, its simplicity is its durability. The expense of crushing rock or cement with this Mill is less than one-half the expense of any other Stamp Mill, and less than one-half the cost. For further particulars inquire of

A. BICKNELL, Agent,
Nevada City, California,

Or of THE WILSON STEAM STAMP MILL CO., 326 Walnut street, Philadelphia, Pa.

Notice.—All persons are hereby warned not to manufacture or use any Steam Stamp Mills that are an infringement on the Wilson Patents, as they will be prosecuted to the utmost rigor of the law.

F. R. WILSON,
20v19-tf Supt. W. P. S. S. M. Co., Philadelphia.

VARNEY'S PATENT AMALGAMATOR,

These Machines Stand Unrivaled.

For rapidly pulverizing and amalgamating ores, they have no equal. No effort has been, or will be, spared to have them constructed in the most perfect manner, and of the great number now in operation, not one has ever required repairs. The constant and increasing demand for them is sufficient evidence of their merits.

They are constructed so as to apply steam directly into the pulp, or with steam bottoms, as desired.

This Amalgamator Operates as Follows:

The pan being filled, the motion of the muller forces the pulp to the center, where it is drawn down through the aperture and between the grinding surfaces. Thence it is thrown to the periphery into the quicksilver. The curved plates again draw it to the center, where it passes down, and to the circumference as before. Thus it is constantly passing in a regular flow between the grinding surfaces and into the quicksilver, until the ore is reduced to an impalpable powder, and the metal amalgamated.

Setlers made on the same principle excel all others.—They bring the pulp so constantly and perfectly in contact with quicksilver, that the particles are rapidly and completely absorbed.

Mill men are invited to examine these pans and setlers for themselves, at the office, 229 Fremont street,
1v1 San Francisco.

TO MILLMEN.

FOR SALE CHEAP.—A 10-stamp mill complete; engine about 35 horse-power; cylinder 12-inch bore and 30 inch stroke; boiler 16 feet long and 48 inch diameter; weight of stamps complete, 650 pounds. The whole is as good as new; has only been running four months. Will sell either engine or battery separate, and deliver it on the railroad at Auburn if required. For particulars apply to W NAGEL, 702 Bush street, San Francisco, or to MOUNTAIN CO., Forest Hill, Placer county. 16v20-3m

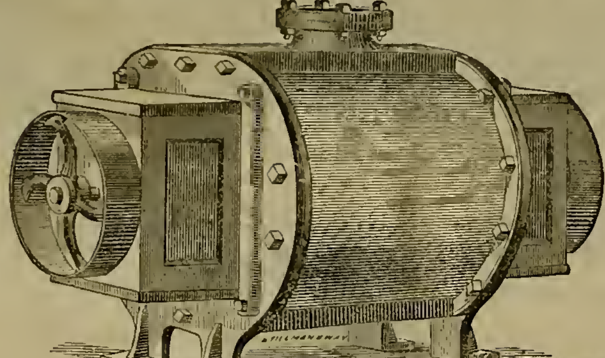
---

ROOT'S PATENT FORCE BLAST ROTARY BLOWER.

MANUFACTURED BY KEEP & BARGION,

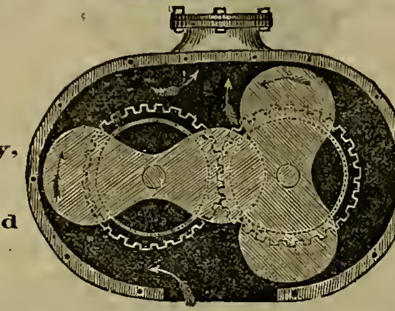
At the Globe Iron Works, Stockton, California.

Awarded the First Premium at the Paris Exposition.



Patented Nov. 1st, 1864; July 24 1866; and Oct, 9, 1866.

ADAPTED FOR **Smelting, Foundry, Mining and Steamships.**



REQUIRES **Fifty Per Cent.** LESS POWER **Than any Blower** Now in use.

One of these Blowers may be seen on exhibition at W. T. Garratt's Brass Foundry, corner of Mission and Fremont streets. They are also in use at the Almaden Quicksilver Mine; Gridley's Foundry, Gold Hill, Nevada; Ætna Iron Works, San Francisco, and many other places.

Caution.—Purchasers will find it to their advantage to apply direct to the Stockton Agency, as certain parties, not authorized to manufacture the Blower, have put in the market machines of inferior construction, which do not answer all the requirements of the genuine article.

Quartz, Saw and Grist Mill Irons, Steam Engines, Horse Powers, High and Low Pressure Steam Engines, Steamboats and Propellers, made at short notice.

For circulars and further information, address

Important to Assayers.

Crucibles.

The Patent Plumbago Crucible Co.

Manufacturers of all kinds of

Melting Pots, Portable Furnaces,

CRUCIBLES, and other fire-standing Goods,

Battersea Works, London.

THE MORGAN PATENT CRUCIBLES have uniform quality, never crack, withstand the greatest heat without danger; heats more rapidly than any other; change of temperature has no effect on them; stand on the average forty to fifty pourings.

CERTIFICATES:

United States Branch Mint, San Francisco, Cal., March 12, 1869—Messrs. A. S. Hallidie & Co., Agents Morgan Crucible:—I have carefully tested the Morgan Patent Plumbago Crucibles purchased from you for the U. S. B. Mint, and cheerfully certify to their superiority and economy over all other Crucibles used by and under me. They are fully what you represent them, and I shall continue to use them in preference to any other. J. M. ECKFELDT, Melter and Refiner, U. S. B. Mint.

Eagle Brass Foundry, 206 Fremont street, San Francisco 12th March, 1869—Messrs. A. S. Hallidie & Co., 519 Front street—Gentlemen:—We have used and tested the Morgan Patent Plumbago Crucible, for which you are agents, and pronounce them superior to and cheaper than any Crucible used by us heretofore. GREENBERG & MOORE.

Messrs. A. S. Hallidie & Co.:—We have thoroughly and severely tested in every way the Morgan Patent Plumbago Crucible obtained by us from you, and find them superior to any we have yet tried, although we have used every pot obtainable in this market, we have none equal to the above, and concede your claims for them. We think they will average 45 pourings of brass. GALLAGHER, WEED & CO., California Brass Works, 125 Front street, San Francisco.

Assay Office of H. Harris, Silver City, Nevada, April 24, 1869—Messrs. A. S Hallidie & Co.—Gents.:—I received from you three Crucibles of the Morgan make, which I have used since their arrival, and tested by constant use. Since 1847, when in the New Orleans Mint, I have always preferred the Crucible of Dixon's make over Adus, Gautier, and Taunton, Mass. Yours I find to be not alone of more finished make, but to stand double or treble the work of Dixon's Crucibles. The No. 12—the smallest sent—has stood so far 32 meltings, and is as good and sound as when received. Your Crucibles do not scale off like others; and as they are forty per cent. cheaper, I do not see why they should not be preferred by all assayers on account of durability and cheapness. Yours respectfully, H. HARRIS.

On hand and for sale by the Agents,

A. S. HALLIDIE & CO.,

THE NEW AGE,

A Weekly Journal of Sixteen Pages.

The "Official Organ" of the I. O. O. F. on the Pacific Coast.

Is devoted to Odd Fellowship, the Arts and Sciences and General Literature; and as a family paper is not surpassed by any journal in the United States. Subscription price per year by mail, $5. Delivered in the city, per month, 50 cents. Office, Odd Fellows' Hall, 327 Montgomery street, San Francisco. 19v19

WIESTER & CO.,

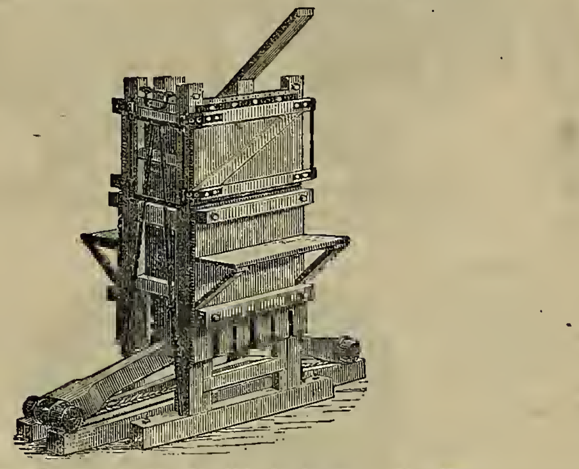
PATENT BROKERS,

No. 314 Bush Street, San Francisco.

PATENTS BOUGHT AND SOLD ON COMMISSION.

For the benefit of those who live at a distance from the city, we give below a brief description of a few of the valuable Patents which we have in our office. It may be well to state here that no Patent is received by us for negotiation until it is first endorsed by reliable experts, to whom each is subjected for acceptance or rejection. We treat all patents alike, recommending only where true merit is found in the invention.

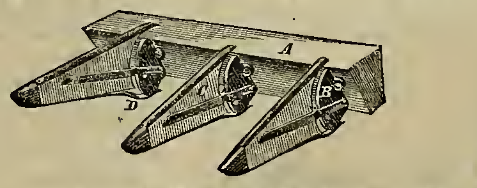
EAGLE HAY PRESS.



PATENTED JANUARY 10, 1865, AND JULY 24, 1866.

Here is an invention that we take pleasure in recommending. There is probably no farming implement more perfect in its line than this Press. It has advantages over any and all other Presses now in use. It costs only $300 and weighs only 1,500 pounds, which is $100 lower in price and 1,500 pounds less in weight than any other good Press on the Pacific coast. Three men and a pair of horses with this Press can bale from ten to fifteen tons per day, each bale weighing from 250 to 350 pounds. The power is applied by means of two lines acting on the principle of the toggle-joint, and the pressure acquired as they approach a vertical position can scarcely be estimated. On account of the great power obtained in this Press, it is well adapted to baling hides, rags, wool, cotton, etc. They can be built at any blacksmith and wagon shop. They cost to manufacture $150 less than any other first-class Press in the United States. A large number have already been sold, and all are giving good satisfaction. The Right to California, Oregon and Nevada will be sold in States or counties. We keep on hand well built sample Presses to furnish to parties buying territory. Any information in regard to the Press or territory can be obtained by addressing WIESTER & CO., 314 Bush street, San Francisco.

BONNEY'S IMPROVED GRAIN LIFTERS.



Patented July 21, 1868, and September 28, 1868.

Mr. O. BONNEY, Jr., of San Francisco, has invented and patented a simple and practical device for raising fallen down grain, that it may be secured by the knives of the header. Practical farmers and those whose interests are closely allied with them, can testify to the great amount of grain that cannot be gathered by the heading machines in use, and which is annually lost to themselves and the country.

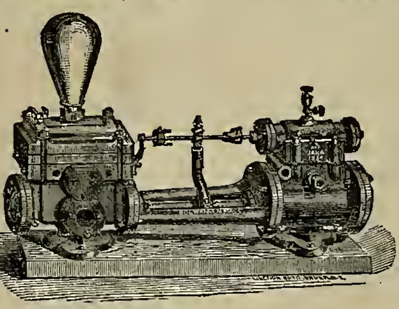
It has been estimated that with the ordinary Harvester one bushel to the acre, on an average, is annually wasted in the State of California. Taking this estimate, which we think is very low, by the use of BONNEY'S IMPROVED GRAIN LIFTERS there would be annually saved to the people of this State more than 700,000 bushels of wheat, 400,000 bushels of barley, and 40,000 bushels of oats. In the above cut three Lifters are represented. A is the header-beam, b an iron shank firmly bolted to the beam, to which the finger or lifter, c, is fastened by means of a joint bolt through the iron and the back part of the shank, b. The lifter has an iron point, and is bound with iron, which makes it very durable. They are smooth, affording no chance for grain to hang and burden a team. D is a strip of spring steel, and draws the point of the finger downward. By means of a stop-bolt through the front part of the shank, b, any angle can be given to the Lifter. They can be varied from one inch to two feet from the ground. By elevating the Lifters, they become a complete substitute for what are termed "trinklers," allowing the knives to run close to the ground. The hinge motion of the Lifters prevents them from injuring the header-beam in passing over rough ground. The entire weight of a full set of eight Lifters is forty-eight pounds. One minute is sufficient time to put on or take off each finger.

We claim that this auxiliary for harvesting is much superior to anything else of the kind ever invented, and are prepared to prove the same in the field. A single Lifter will be sent (C. O. D.) at the retail price—five dollars—to any person who may wish to examine them either with a view to buy territory or to purchase Lifters for his own use. If the Lifter is not satisfactory, it can be returned, and we will refund the money, less express charge on the Lifter. We will furnish Lifters at what they cost to manufacture to any person who buys a County or State Right. They can be made at any blacksmith shop, and allow a handsome profit. For Lifters or Rights address WIESTER & CO., 314 Bush Street, San Francisco.

☞ We have for sale the Right of A NOVEL AND VALUABLE LITTLE INVENTION for the city of San Francisco. One machine will go with the right. The machine can be attended by a man or small boy, and will yield to the owner a net profit of from two to four dollars per day. The present owner has built up a paying business, but is induced, at the request of friends, to relinquish it and go East. The Right and the Machine will be sold for the small sum of $175.

WIESTER & CO.,
314 Bush Street, San Francisco.

KNOWLES' PATENT STEAM PUMP.



This Pump has received the HIGHEST PREMIUM at every Fair where it has been exhibited. It is of superior make and finish; has all ground joints; no packing required. It is positive in its action. It is impossible to stop it on centers. It will always start without using a starting bar. We have two hundred different styles and sizes adapted for Factories, Steamships, Sugar Refineries, Breweries, Distilleries, Gas Works, Oil Works, Soap Works, Paper Mills, Tanneries, Bleacheries, Laundries, Railroad Purposes, Quarries, Petroleum Mines, Drainage, etc. Large Pumps for Water Works. Fire and Wrecking Pumps. ☞ Pumps guaranteed for every situation.

E. T. STEEN & V. CUSHING,
Sole Agents for the Pacific Coast,
No. 9 FIRST STREET, SAN FRANCISCO.

NEW AND SECOND-HAND ENGINS, BOILERS, and MACHINERY OF ALL KINDS, constantly on hand.

SCIENTIFIC PRESS.

AN ILLUSTRATED JOURNAL OF SCIENTIFIC AND INDUSTRIAL PROGRESS,

Mining, Farming and Mechanic Arts.

BY DEWEY & CO.,
Patent Solicitors.

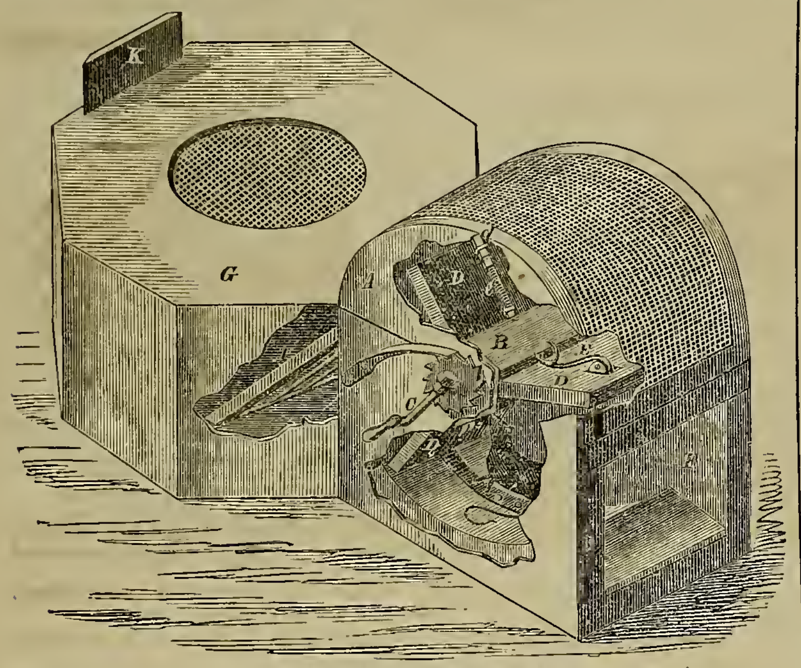
San Francisco, Saturday, May 28, 1870.

VOLUME XX.
Number 22.

Improved Animal Trap.

California has the reputation of being prolific geologically as well as botanically. The number of small animals which live in our fields and which take up their abode in our dwellings and elsewhere, is by no means small. Hence a device to effect their capture is of interest to the farmer, the housekeeper and the naturalist.

Lately a very neat and apparently effective device for entrapping small animals has been patented, and we give an illustration of it to-day. It consists principally of a revolving wheel operated by a spring in a suitable wheel-house, for catching the animal, and a box or cage for holding him after capture.



LORD'S IMPROVED ANIMAL TRAP.

The wheel is here represented with three wings, D, but some other number might be used. It is revolved inside of a suitable box or house, A, by means of a coiled or other suitable spring, coiled around the shaft or otherwise properly affixed. This spring may be wound up in the usual manner by means of a crank, C, a ratchet and pawl serving to retain the shaft after the spring has been wound up. The bottom of the wheel-house is curved. so as to allow the wings to sweep along it.

Attached at some suitable point on each of the wings, D, is a sliding bolt, *d*, which is operated by means of a small spring, *e*, to throw it out. On the curved floor is a catch, *f*, which catches the bolt, *d*, and thereby retains the wheel until released, as afterwards to be shown. A suitable lever, E, made in the form of a bell-crank, on each wing, has one arm passing through the wing and secured to the bolt, *d*, while the other arm extends upward on the opposite side of the wing, and has its end formed into a hook for holding the bait. The trap is set by winding up the spring, by means of the crank, D, and baiting the hooks.

The animal enters the wheel-house through the opening, F, and, as seen in the cut, by nibbling at the bait releases the bolt, *d*. The spring, B, then revolves the wheel and the descending wing strikes the animal from behind, forcing him inside the wheel, while the bolt on this wing catches at *f*, imprisoning the animal and setting the trap for another victim.

Attached to the wheel-house is a large cage or chamber, G, which opens towards the wheel, where there is an inclined gate, I, hinged at the upper end, and opening only on pressure from the wheel-house side. The animal, in its efforts to escape, will attempt to pass into the chamber, G, which he can do by running against the gate, I. Once in this chamber, however, he is securely imprisoned. A small sliding door, K, is arranged on the cage, G, through which the captured animal may be removed when desired.

By this device any number of animals may be secured without the necessity of resetting the trap each time. It is an improvement on that class of articles which has a universal use, and is at once a most ingenious and effective arrangement.

A patent has been granted to the inventor for this trap, through the Agency of the SCIENTIFIC PRESS. Applications for further information may be addressed to James H. Lord, San Francisco.

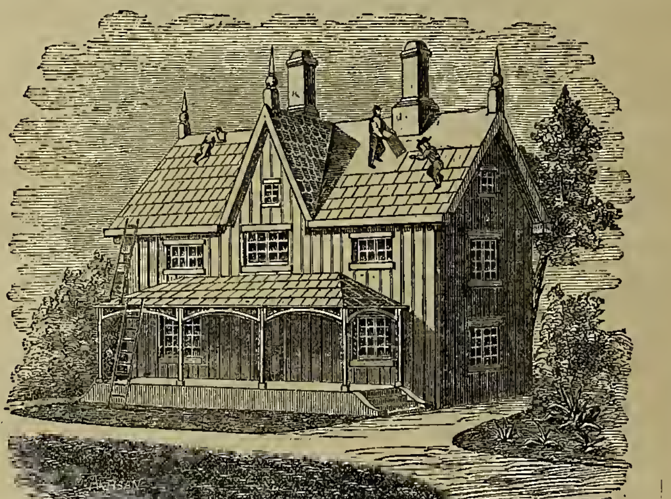
* * *

FOURTH OF JULY.—A most intelligent action is to be taken by the northern counties by combining for a grand coöperative celebration of the coming Fourth of July. Such meetings tend not only to the diffusion of general good feeling, but also to stir up people and keep them ever advancing in all their pursuits.

Hickcox's Corrugated Metallic Shingles.

The perishability of wood and the gradually increasing price of good qualities, as our forests grow continually thinner and thinner, are leading more and more to the substitution of the metals, and iron especially is ever extending its sway and encroaching on the domains formerly occupied by other materials.

The use of sheet metal for roofing purposes has been long familiar to us in the shape of tin (or, more properly, tinned) plates. The inventor of the present device has gone a step further, and combined, as he claims, all the advantages of the metal with those of the common wooden shingle, without any of their defects. This he accomplishes by the use of corrugated metallic shingles, so formed and arranged as to lap closely over one another and prevent all leakage, which has been so great a trouble in too many cases heretofore.



CORRUGATED METALLIC SHINGLES.

Fig. 2.

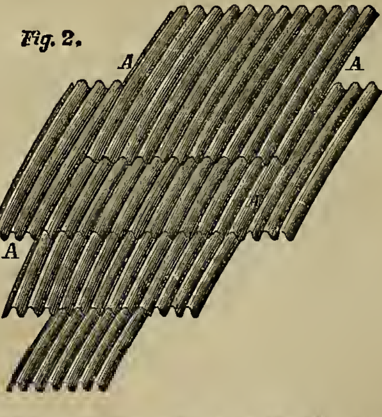


Fig. 3.

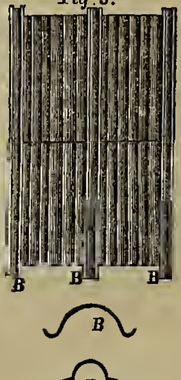

Sheets of iron or other suitable metal, generally with the dimensions of nine by fourteen inches, are corrugated longitudinally, as shown in Fig. 2. Moreover, in order to make these fit tightly into one another when laid, they are given a slight longitudinal curve, which may be seen by closely examining this figure. They are laid in courses on the roof after the general manner of laying the wooden shingles, each course overlapping the one next below, care being taken to break joints, and the corrugations of one row being fitted into those of the next. The single shingles are fastened in place by nails, which are covered up and protected from the influence of the weather by the overlapping pieces, which fit all the more closely since their curved shape gives them a spring-like action when tightly nailed in place. In the first figure a representation is given of the application of these shingles to the roof of a cottage. The shingles may be painted before being laid, and a coat of paint applied to them when in place, if desired.

The inventor does not confine the application of his shingles to the roof, but uses them also for protecting the sides of a house. In this case they are laid lapping but without breaking joints, and the continuous vertical joints are covered by sheet-metal battens, represented at B, Fig. 3. These battens are curved into any suitable form, specimens of the cross-section of two of these being given in the two diagrams, B, B, under Fig. 3.

A patent for this device was granted in February, 1870, to Thomas N. Hickcox & Co., of New York. Applications for further information may be addressed to T. N. Hickcox & Co., 280 Pearl street, New York.

Elevated Railways.

The New York Society of Engineering held their usual monthly meeting on the evening of March 20th, James A. Whitney, President. The regular paper by Mr. C. Williams treated of "Old and New Methods of City Transit," and in the main treated of elevated railways and the wire rope and pneumatic systems of propelling cars on such lines.

One of the earlier methods proposed for constructing elevated railways embraced the use of only one rail. It was patented in England in 1821. This was to be laid upon a horizontal sleeper carried by upright posts ranged in line. The car was to be made in two longitudinal sections, connected at the top, and carrying centrally, near the roof, two or more wheels running upon the track. The car was thus, as it were, placed outside of the track. Sixteen years afterwards a New Jersey inventor, one Uri Emmons, took up and improved upon the idea, by applying guide rails to steady the bottom of the cars by rollers attached to the same and running upon the guide rails, which were to be affixed to the sides of the posts. The shape of the car was objectionable, and it is doubtful if the cost, taking the guide rails into account, could be much less than that of a two-rail track like that of the West Side Elevated Railway in New York City. To this last-named line, however, the writer brought forward the objection that the rope system of traction adopted must necessarily jar the car in an inordinate degree in starting, and tend to the rapid deterioration of the working mechanism. He claimed that, inasmuch as the car, in recent public experiments, had not been stopped between the two ends of the line as now completed, no evidence had been offered to show the fallacy of the objection urged. He thought it possible, however, that one or all of the two or three plans made public in this country for gradually starting the car in its connection with the rope, might be made practicable. These are founded upon the use of pulleys affixed to the car and clutching the rope, the connection being complete when the motion of the pulleys upon their axes is stopped by suitably arranged friction brakes carried by the car. The writer advocated, for New York City, the substitution for the ordinary plan of a simple elevated track, the forming of an elevated street above Broadway, provided with sidewalks, having two tracks for cars and accessible by commodious stairways and lifting apparatus or elevators.

The various projected modes of driving the cars was considered at length with reference to the application of pneumatic or air pressure. Tanks holding air compressed to several atmospheres and arranged to operate the engines of the car, have excited sanguine hopes with some projectors, but their enormous bulk and great weight, if made capable of holding enough to propel the car for any distance without displacement, will prove an unsuperable obstacle to the adoption of the plan. That tried in England thirty years ago and given up, was constructed with a pipe through which a piston was forced by air pressure. In the top or upper side of the pipe was a slat which allowed the passage of a connecting bar uniting the piston with the car. The fatal defect with this was the leakage of air through the valve, which evaded the numerous ingenious expedients that were devised to prevent it. A pressure of nine pounds to the square inch upon the piston was readily obtained, and cars were run at the rate of seventy miles an hour on exceptional occasions. An improved valve might yet make this method a practical success, and that such an improvement would be thought of at no distant day, the writer thought quite probable. In the meantime, however, attention should be directed to another system of using air for the purpose indicated, which, while including tanks on the cars and a pipe laid along the track, theoretically at least, obviated the difficulties incident to the two methods previously referred to. The tanks, as the car moved upon the track, are to be brought into communication, at intervals, with the pipe charged by appropriate blowing apparatus with compressed air. This is to be done by automatic couplings, so that the tanks will be constantly kept filled to the required pressure to work the engines upon, and calculated to drive the car.

At the same meeting Mr. R. Chesebrough explained his plan of constructing an elevated railway with inclines of half a mile in length, the sections being steepest at their upper portions, and in lieu of ordinary construction, formed upon the principle of the suspension bridge with lateral supporting cables. At the foot of each incline was represented an hydraulic apparatus, intended to lift the car to the head of the next incline, and so on throughout the length of the line. Considerable discussion *pro* and *con* was had upon the merits of the proposed system, the chief objections being the probable retardation of the cars by head winds, the resisting action of snow and frost upon the rails, to the movement of the cars, and the unsteadiness possible from the suspension and consequent non-rigidity of the inclines.

◆

Coal Mines on Fire.

There are many instances of vast masses of coal which have been ignited and have been burning for years. When once well lighted and all communication with the external air is not entirely cut off (and some imperceptible fissures are quite sufficient to prevent this), then the devouring element pursues its course without interruption. It partially burns the coal, which has nearly the same chemical composition as the diamond, and a considerable degree of hardness, but without transparency or crystallization. It calcines the sandstones and adjacent schists, changing their colors to a sort of red, and altering their composition. At Brulé, near Saint-Etienne, there is a coal mine which has been on fire from time immemorial. The soil at the surface is baked and barren; hot vapors escape from it; sulphur, alum, sal-ammoniac and various natural products are deposited on it; it might be supposed to be a portion of the accursed cities formerly consumed by the fires of heaven and earth.

Other burning coal mines are cited in France; for example, those of Decazeville, in Aveyron, and of Commentry, in the department of Allier. The inhabitants have even, for a long time, kept up these fires for the sake of working the aluminous salts which are given off from the coal and are deposited on the surface of the soil as whitish efflorescences.

In the carboniferous basins of Saarbrück and Silesia there are likewise coal mines which have been on fire for a long time. In Belgium, between Namur and Charleroy, at a place called Falizolle, the fire has been alight for many years. The inhabitants formerly were in the habit of working the coal on their own account. Now it frequently happened that two parties came in contact, causing endless disputes and often sanguinary fights. A favorite way of keeping rivals or competitors at a distance was to throw pieces of old leather on a burning brazier, causing an insupportable stench. One day the fire extended also to the coal, since which time it has never ceased burning. The fire, which burns underground, is seen through fissures in the surface. Sulphur deposits itself round these vents and acid gases are evolved.

In England, especially in Staffordshire, the ignition of the coal has produced surprising effects of alteration in the measures containing coal. The sandstones have become vitrified, baked and dilated by the fire, the banks of plastic clay hardened and changed into porcelain.

In the environs of Dudley there was formerly a coal mine on fire. The snow melted in the gardens as soon as it touched the ground. They gathered three crops a year; even tropical plants were cultivated; and, as in the Isle of Calypso, an eternal spring prevailed. In another Staffordshire colliery, the firing of which dates many years back, and which is called by the inhabitants "Burning Hill," it was noticed, as at Dudley, that the snow melted on reaching the ground, and that the grass in the meadows was always green. The people of the country conceived the idea of establishing a school of horticulture on the spot. They imported colonial plants at a heavy expense and cultivated them in this kind of open-air conservatory. One fine day the fire went out, the soil gradually resumed its usual temperature, the tropical plants died and the school of horticulture was under the necessity of transferring their gardens elsewhere.—*Underground Life.*

Prospecting in Siberia.

Until almost thirty years ago, furs were the chief export article of Siberia, but since then the discovery of its rich auriferous deposits has made gold its most important produce. The precious metal is found on the western slopes of the Ural chain in West Siberia; but the most productive diggings are situated in East Siberia, where they give occupation to thousands of workmen and riches to a few successful operators.

The vast territory drained by the Upper Yenissei and its tributaries, the Superior and the Middle Tunguska, consists, for the greater part, of a dismal and swampy primeval forest. A journey through these sylvan deserts is said to be one of the most tedious and fatiguing tours which it is possible to make. Up-hill and down-hill, a narrow path leads over a swampy ground into which the horses sink up to their knees. The eternal sameness of the scene—day after day one constant succession of everlasting larches and fir trees—is as wearying to the mind as the almost impossible road to the body. But here and there the forest opens, a long row of huts extends along the banks of a rivulet, and hundreds of workmen are seen as busy as bees. These are the gold fields; the sands of these swampy lands are mixed with gold, and their fortunate possessors would not exchange them for the finest meadows, cornfields or vineyards.

Fedor Popow, a hunter of the province of Torusk, is said to have been the first discoverer of gold in Siberia; and government having granted permission to private persons to search for the precious metal, a few enterprising men directed their attention to the wild spurs of Sajan mountains. A brilliant success rewarded their efforts. In 1836 an exploring party discovered a rich deposit of auriferous sand near the banks of the Great Birussa; and in 1839-'40, similar deposits were found along several of the tributaries of the upper Tunguska, and still farther to the north, on the Oktolyk, a rivulet which flows into the Pit. The expenses of a searching-party amount, an an average, to $3,000; and as very often no gold whatever is found, these hazardous explorations not seldom put both the purse and the perseverance of their undertakers to a severe trial.

Of the difficulties which await the gold-seekers, a faint idea may be formed on considering that the whole of the auriferous region, which surpasses in size most of the European kingdoms, consists of one vast forest like that above described. Patches of grass-land on which horses can feed are of very rare occurrence and damp moss is the only bed afforded. As the gold-seekers are very often at work a long distance from any village, they are obliged to carry all their provisions along with them. Their clothes are almost constantly wet, from their sleeping in the damp forest, from the frequent rains and from their toiling in the swampy ground. Scarcely have they dug a few feet deep when the pit fills with water, which they are obliged to pump out as fast as it gathers, and thus, standing up to their knees in mud, they work on until they reach the solid rock, for then only can they be certain that no auriferous layer has been neglected in their search. When the winter, with its deep snowfalls, suddenly breaks in upon them, their hardships become dreadful. The frost and want of food kill their horses, their utensils have to be left behind; and, dragging their most indispensable provisions on small sledges, they are not seldom obliged to wade for weeks through the deep snow before they reach some inhabited place.

But even in winter exploring parties are sent out, but only for the more accurate examination of *very* swampy grounds which have been previously discovered, and where it is less difficult to work in the frozen soil than to contend with the water in summer. The hard ground has to be broken up with picks, and the sand, thus loosened, thawed and washed with warm water. They sleep on the bare ground in huts made of branches of trees. It requires the iron constitution of a Siberian to bear such hardships, to which, indeed, many succumb.

The fortunate discover of a gold deposit obtains the grant of a lot of ground 600x15,000 feet. Two adjoining lots are never granted to the same person, but subsequent purchase or amalgamation is permitted. At first, government laid a tax of 15 per cent. on the produce, then doubled this, but subsequently returned to the primitive tax or even to five per cent. for less productive mines. Besides this tax from five to eight dollars per pound, gold must be paid for police expenses. A lease is for 12 years only, when the diggings revert to the government, and a new lease must be purchased, As the climate limits the working to four months (May to September), the period of the concession amounts really to not more than four years.—*Dr. G. Hartwig.*

A Beautiful Site.—The site chosen for the grand park at San Francisco is altogether lovely. The natural sites of the New York, Chicago, Boston, Brooklyn, London and Paris parks, do not begin to compare with this in point of natural beauty. Here there are hills, lakes, valleys, and ocean, which require but a little labor to make them suitable for any park purposes. The sites of the other parks had all these advantages save the ocean—and this is the greatest of all. This San Francisco park fronts on the ocean 3,300 feet immediately south of the Cliff House, and runs into the sand hills towards the city three or four miles. The sand and winds have to be contended against while the park is being made and planted, but science aided by money will soon lay the shifting sand and cover it with perpetual verdure. The drives can be made the most picturesque on the continent—and the most renowned—but it will require time and money. There are natural lakes on that site which can be scooped out to any desirable size, and there is a splendid hill almost in the center, which should not be lowered by a single shovelful. The grounds are large, containing over 1,000 acres. San Francisco is to be congratulated on securing such a magnificent site, for no other town in America has its equal. And the ground has not cost her a dime. It is a gift, in fact, and San Francisco can well afford to spend a million of dollars in improving it.—*Sacramento Bee.*

A Beautiful Cave.—The celebrated alabaster cave is situated in the foothills of El Dorado, between the north and south forks of the American river, about 13 miles from Folsom, and can be reached from this place on the road by crossing the bridge at Mormon Island and taking Shaw's road, which winds on an easy grade among the high hills about Bear mountain, that attain an elevation of 2,500 feet, and amid which the scenery is truly grand and magnificent. To the east the eye rests upon the snow-capped Sierras, and upon intervening hills, clothed to their summits with dense foliage of every shade of emerald; while on the west and south lies spread out the beautiful panorama of the Sacramento valley, with the coast range and Mount Diablo in full view; while on the north the eye rests upon the Buttes and the intervening valleys. Taking in all at a glance, no more beautiful and exhilerating picture can be seen in the State. The other road, crossing the American river, runs through the wooded foothills of Placer crossing Gwynn's bridge—a fine suspension—at Rattlesnake bar on the north fork, the distance by either road being about the same. The cave is situated in a limestone hill, where excellent quarries exist, and was discovered about 15 years since while blasting out limestone. For many years it has been a favorite place to visit, and if it has lost the freshness of a new discovery, it still appears as beautiful as ever.—*Folsom Telegraph.*

Home Manufactures.—There is a great deal of truth in the following from an exchange, and we commend it to the attention of those who do not believe in home industry: "It is too much the habit of people to look with disrespect or distrust upon home products, and to cherish the idea that nothing can be good or reliable that has not a metropolitan endorsement. No town or village can prosper unless the business men, we do not mean merchants only, but mechanics and manufacturers of all kinds, are sustained. Every industrious mechanic is a blessing to the town. Every manufacturing establishment, however humble, is a public benefit. Every chair, table, bedstead, bureau, wheelbarrow, harness, pair of boots, or other article, made at home, keeps money from going abroad, and to just that extent helps the town generally."

The Deepest Mine in the World.—The Rose Bridge Colliery at Wigan, Lancashire, England, is 2,424 feet, or nearly half a mile, deep. The increase of temperature in going down through the strata is said to have been about 1° Fah. for every 54½ feet. At the bottom of the mine, the temperature is 79° Fah. in the open pit, and 93½° in the solid strata. There is plenty of coal reported much deeper, but it is an open question whether it will pay to mine it.

Mechanical Progress.

Determination of Carbon by the Colorimetric Process.

The following notes by J. Blodgett Britton, of the Iron Masters Laboratory, are taken from the *Journal of the Franklin Institute* for May:

"Professor Eggertz, of Fahlun, Sweden, called the attention of metallurgical chemists to the fact that when pure metallic iron is dissolved in nitric acid, the solution, if not too concentrated, is colorless; but when steel or iron containing carbon in combination is substituted the solution is colored, and the shade varies exactly in proportion to the amount of carbon present; and, based upon this fact, he suggested a method whereby carbon determinations, sufficiently accurate for many commercial purposes, could be made with facility.

A modification of this method affording exceedingly accurate results, has been in use at the Iron Masters' Laboratory. Instead of a single tube containing a standard solution for comparison, a number of tubes having solutions differently standardized, are employed. These are arranged in a walnut-wood frame, with spaces between for placing the tube containing the solution to be tested.

The tubes are ⅝ of an inch in diameter and 3¼ inches in length, filled with water and alcohol colored with roasted coffee, and hermetically sealed. The solution in the tube to the left has its color to correspond exactly with one produced by 1 grm. of iron containing .02 per cent. of combined carbon dissolved in 15 C. C. of nitric acid. The solution in the tube next to it has its color to correspond with one produced by the same quantity of iron, but containing .04 per cent. of combined carbon, and so with each of the other tubes, increasing .02 per cent. of carbon in regular succession to the right, the last reaching 30 per cent.

The process is conducted as follows: One grm. of the finely divided metal is put into a tube of about one inch and a half in diameter and ten inches long, and digested for fifteen or twenty minutes in 10 C. C. of nitric acid of a little more than 1.20 s. g., free from chlorine. The solution is then poured into a beaker, and a small portion of metal which remains undissolved, and adheres to the bottom of the tube, is treated with 5 C. C. of fresh acid, exposed to a gentle heat till dissolved, and added to the other. The contents of the beaker, when cool, are filtered into a tube 5 inches long and of precisely the same diameter as those in the instrument.

After the filtered solution has remained for some minutes of the temperature of the atmosphere, and its color become fixed, the tube is placed in the instrument and the carbon determined by a comparison of shades—the determination may be made readily as close as .01, or one-hundredth of one per cent."

Pulleys and Belting.—The smooth side, or hair side, of the belt, is placed next the smoothly turned cast-iron pulley, because the adhesion of these two smooth surfaces is a greater preventive against slipping than the friction of two rough surfaces would be. This is because a rough surface in rapid motion catches and carries in its inequalities sufficient air to prevent intimate contact with another surface. Another reason given for placing the smooth side of a leather belt next the pulley is, that the other side, or flesh side, is less liable to crack, and will best bear the greater amount of stretching to which the outer surface of a belt is of course subjected. Still more perfect contact is secured by covering the pulley itself with leather, smooth side out; and this is yet further improved by using castor oil as a dressing.

The "Sector" Magnet.—The *Artisan* of May 11th says: "We are informed on excellent authority of some improvements lately made in electro-magnets, which promise a step toward the successful application of electricity as a motive power. A magnet weighing but fifty pounds is said to have lifted one hundred and six pounds, at a distance from its poles of one and three-quarter inches, the battery used consisting of nine eight-inch Bunsen cells." The limbs of the magnet are of flat sector shape; hence the name. The journal aforesaid expects to give full particulars soon.

Utilization of Iron Sands.

Prof. T. Sterry Hnat gives some recent notes upon the Canada iron sands, from which we condense:

"The black sand may be separated into a magnetic and a non-magnetic portion, the latter predominating in the washed sand. While the magnetic part is nearly pure magnetic iron ore, the other portion contains from 30 to 35 per cent. of titanic acid, and consists in great part of titanic iron (menaccanite), with some admixture of garnet. Successful attempts have been made to work these iron sands at Moisie, where they are treated in bloomery fires, and are reduced without difficulty. The bar-iron produced is of excellent quality, and contains no titanium, while the slags hold a great deal of titanic acid as silicotitanate. The layers of iron-sand at the Moisie are very rich; but in many localities there are great quantities which yield by washing from 8 or 10 to 30 or 50 per cent. of heavy black sand. Attempts have recently been made to purify these by means of a magnetic separator. For some of the newly-proposed processes of direct conversion, and generally for ore intended for separation, it is deemed desirable to get pure magnetic iron ore. This, in the case of these sands, can only be attained by the use of magnets. Dr. Larne, Professor of Chemistry at the Laval University, Quebec, has contrived for this purpose a simple machine, which appears to be very efficient. This machine, which is fitted with batteries of permanent magnets, occupies a space 6 feet by 5 and 4 feet high. From three tons of sand holding one-third of magnetic ore, it will separate in an hour one ton containing over 99 per cent. of magnetic iron—or 24 tons in 24 hours. The wear and tear and the motive power required are very small, and two men can, it is said, tend ten machines. By proper adjustment this machine may be adapted to the preparation of lean massive ores for the bloomery fire, or for other direct methods of conversion into iron or steel. Meanwhile the deposits of sand, which may be utilized by means of this machine, on the north shore of the St. Lawrence, from the Saguenay to Newfoundland, are practically inexhaustible. Similar deposits have been observed on both shores of Lake Erie. The iron-sands of Taranaki, in New Zealand, are well known; and similar sands, according to Bruno Kerl, are worked in open hearths near Naples. Black magnetic iron-sands are found in greater or less abundance in numerous localities along the seaboard of Connecticut and Rhode Island. The utilization of these abundant deposits of an ore free from phosphorus and sulphur is a problem worthy the attention of metallurgists, and is already attracting considerable attention."

A Remarkable Watch.—The *Artisan's* reporter thus describes a watch made at the works of the American Watch Co., Marion, New Jersey: "It is a minute repeater, being made to tell the time in the dark by simply moving a little knob on the exterior, when it strikes the hours and minutes. It is a stem-winder, winding or setting the hands by turning the stem, and winding whichever way the stem is turned. It has also an independent train from the time-works, which carries a quarter and a sweep second-hand, with a stop-motion, for timing races, etc., and what is called a "magic case," making an open-faced or hunting watch at pleasure; and in the case there is a secret receptacle for a miniature. The case has exquisitely engraved upon it a view of the sea-fight between the Monitor and the Merrimac. The pendant represents two entwined serpents; and it, as well as the back of the case, contains valuable precious stones. This watch cost two thousand five hundred dollars."

Welding Metal Plates.—The *Mechanics' Magazine* describes an arrangement for welding boiler plates instead of riveting them. The furnace is so arranged with an overhanging girder that the heated boiler seam may be run under the steam hammer by means of a carriage, and the welding quickly effected.

Large Casting.—The Corliss Works, at Providence, have just turned out a propeller screw for the U. S. steamer Pompanoosuc, 18 feet in diameter. It is a solid casting of bronze, weighs 35,273 pounds, and is worth $20,000.

Scientific Progress.

Influence of Pressure on Chemical Phenomena.

C. Widemaan details some experiments on the subject in the *Journal of Applied Chemistry*. Zinc and hydrochloric acid are placed in a glass tube, which is connected by a capillary copper pipe with a cast-iron receiver, to which is attached a powerful hydraulic press. "The production of hydrogen decreases rapidly as the pressure increases; also the solution of carbonate of lime in nitric acid is stopped by pressure. The same phenomenon is noticed when iron, tin, aluminum, or the sulphuret of iron, are brought in contact under high pressure with acids; the decomposition of water by the means of an electrical current is also prevented by pressure. If an amalgam of sodium is inclosed with water in a glass tube, the oxidation of the sodium is nearly prevented in consequence of the pressure caused by the accumulation of the hydrogen.

We have tried whether the chemical phenomena taking place at our usual temperature and atmospheric pressure would not have their action increased if they were produced in a vacuum. Our experiments have confirmed this. M. Cailletet assimilates the production of gases in the decompositions to a simple phenomenon of ebullition 'which appears to demonstrate,' says he, that 'affinity is not a particular power, but that chemical combinations and decompositions are immediately under the dependence of mechanical phenomena.'"

Atmospheric Organisms.—The Boston *Journal of Chemistry* brings up several proofs that Prof. Tyndall's organic motes in the atmosphere are not a new discovery,—and says he has merely pointed out a striking method of showing the fact of their existence to the eye. Dr. Angus Smith, who has been for some years experimenting upon the subject, is quoted. In 1848, he made a report to the British Association, in which occurs the following paragraph: "Animalculæ are now generally believed to come from the atmosphere and to deposit themselves on convenient feeding places; that is, they only appear where there is food or materials for their growth, and they prove, of course, the existence of that continuation of elements necessary for organic life. At the same time, their presence is a proof of decomposing matter, as their production is one of the various ways in which organized structure may be broken up."

Dr. Smith also remarks that, although some of these organized germs are hurtful, it may be that others are required for the maintenance of healthy animal life, exactly as in vegetable fermentation.

Hydrate of Chloral.—This anæsthetic has been the subject of experiments by Dr. W. A. Hammond, which prove that its first effect is to cause congestion of the blood-vessels of the brain, although the directly opposite condition follows. The retina of a rabbit was examined with the ophthalmoscope immediately before the injection of hydrate of chloral into the cellular tissue, and found natural in appearance. Two minutes afterwards another examination showed congestion of the vessels of the retina, which increased for five minutes. In seven minutes, drowsiness came on, and the congestion became less. In ten, sleep was profound, and the retina almost pale. In two hours the ears were cold, and the retina bloodless. In nine hours the animal was found awake, and in every respect in a normal condition. This experiment was several times repeated with the same result.

Ozone and Explosives.—It is a singular fact of recent discovery, that nitro-glycerine, dynamite, iodide of nitrogen, chloride of nitrogen, and some other similar compounds, explode the moment they are brought in contact with ozone. The experiment may be tried by putting a drop of nitro-glycerine into a jar containing ozone. Ordinary gunpowder and picrate of potash gunpowder are very slowly decomposed by ozone.—*Boston Journal of Chemistry.*

Vanadium.—Prof. Roscoe, F. R. S., delivered a lecture on this subject at a late meeting of the Chemical Society. Berzelius found the atomic weight 68.5. It was afterwards observed by Rammelsberg that the mineral vanadinite, a double salt of lead vanadate, and lead chloride, is isomorphous with apatite and with mimetesite, the former containing phosphoric acid, the latter arsenic acid. From this crystallographic analogy it ought to have been concluded that the oxide of vanadium in the vanadinite has the formula V_2O_5, agreeing with the corresponding oxides of phosphorus and arsenic. But Berzelius representing the oxide in question by the formula VO_3, was compelled to regard vanadinite as an exception to the law of isomorphism. Professor Roscoe, having come into possession of a plentiful source of vanadium, determined to ascertain whether there really was such an exception, or whether Berzelius' formula was not erroneous. He proved that the substance supposed by Berzelius to be vanadium is not the metal, but an oxide, and that the true atomic weight of the metal is 51·3. Thus the VO_3 of Berzelius really becomes V_2O_5. The lecturer went on to demonstrate that vanadium, hitherto standing in no definite relation to other elements, must now be regarded as a member of the well-known Triad class of elementary substances, comprising nitrogen, phosphorus, boron, arsenic, antimony and bismuth.

French and English Nitrate of Silver.—R. J. Fowler writes from Paris as follows: "The English are said to dissolve the 'crude' silver in nitric acid, from which the silver is precipitated as chloride, either by chloride of sodium or hydrochloric acid, and this is reduced by chalk and powdered charcoal. The French are said to use the sulphuric acid system—the ingot of silver, containing, probably, copper and lead, is dissolved in *concentrated sulphuric acid;* the operation is performed by heat, and sulphurous vapors are disengaged. Now comes in a process for the production of pure silver which has just formed the subject of a patent. After the sulphate of lead has all separated, and whilst the solution is still warm, it is allowed to cool for twelve hours. During this time the sulphate of silver is deposited in very small crystals, which are also very pure. They are collected by decanting the liquid, and decomposed by being introduced into a strong solution of sulphate of iron. This is well stirred and the resulting metallic silver allowed to settle. This is collected, washed, dried, and melted in a crucible, and gives an ingot of *pure silver*, 1,000 per 1,000; and from this a pure nitrate can be readily obtained with pure nitric acid."

Oxalate of Silver.—We quote the following from a report of a recent lecture by Dr. Odling, F. R. S.: "This salt may be made by adding oxalate of hydrogen to nitrate of silver; oxalate of silver is then precipitated, and this white substance may be heated with impunity, so long as it is not allowed to dry. When it is dry it forms a greyish powder. Dr. Odling put a little of this dry powder in the bottom of a Florence flask, and applied heat. The result was a very slight explosion, and the puff of air thereby caused blew finely divided white metallic silver out of the mouth of the flask. The heat had decomposed the salt into metallic silver and carbonic acid, and the latter gas blew out the silver."

Amorphous Silicic Acid Hygroscopic. Experiments recently instituted result in the following conclusions: Amorphous silica is always hygroscopic after ignition; the degree of hygroscopicity differs greatly, according to the degree of heat the silica has been ignited. When silica has been only feebly ignited, its avidity for the absorption of water, even after the apse of a few minutes, is so great as to cause, if not taken into account, serious faults in the weighing and quantitative estimation. Crystalline silica, even when feebly ignited, is not at all hygroscopic.

Test for Alcohol.—Liehen states that one part of alcohol in 2,000 parts of water may be recognized by pouring a few drops of the liquid into a test tube with a small quantity of iodine and a few drops of caustic soda, and gently heating. If there is any alcohol present a characteristic yellow crystalline precipitate of iodide of formyle is produced.

Mining Summary.

THE following information is gleaned mostly from journals published in the interior, in close proximity to the mines mentioned.

California.

ALPINE COUNTY.

Items.—*Miner*, May 14th: Brick are being hauled for the Leviathan furnaces.... The new furnace at the Silver Glance ventilates the works in a most perfect manner. ....Furnace ventilation for the Globe tunnel has been put in....The M. C. M. Co. will put up one of the Stetefeldt furnaces. ....Mr. Graff comes back from Mexico to take charge of the Schnectady Co's mine on the Tarshish....Mr. Harris is authorized to contract for the sinking of a shaft on the Fremont 300 feet.

Leviathan.—Mr. Heiligendorfer, a German metallurgist, graduate of Freiberg, and for several years in charge of works in Mexico, comes up to take charge of the smelting department.

AMADOR COUNTY.

Coney.—*Ledger*, 21st: The work of putting things in order at the mine was commenced Monday. It is the intention to sink the shaft deeper at once.

Keystone.—This mine can be worked at a trifling expense, and the rock is of uniform quality. Until recently they have been running but 20 stamps, and taking out from $30,000 to $35,000 per month, but now they have 40 at work.

The Wolverine.—This mine is near the Eureka. Last Saturday we saw a handsome chunk of retorted gold, the result of the last run. The rock pays from $12 to $15 per ton.

The Old Amador.—This mine is being worked vigorously. A large flume has been put in the creek to prevent the water from seeping into the mine. The last rock crushed paid over $34 to the ton.

The Ditch.—*Dispatch*, 21st: The new extension of the Butte ditch will be in running order in a few weeks.

BUTTE COUNTY.

Quartz.—Oroville *Record*, 21st: We have been shown by Mr. Hutchins very rich decomposed quartz from his ledge on Butte creek. He has organized a company to work it, under the name of the Golden Sun Co.

CALAVERAS COUNTY.

Palomo Mine.—*Chronicle*, 21st: The proprietors have concluded to erect an additional battery of 20 stamps, and work is already commenced. The main shaft is sunk 300 feet, disclosing throughout a well-defined lode of gold-bearing quartz. Numerous levels are being run from which the rock is being "stoped out" in large quantities.

Angels Camp.—We are informed that a recent clean-up in the mill showed 500 ounces of amalgam.

Hepburn Mill.—A. F. Burr is remodeling the mill preparatory to working rock by a process known only to himself. Mr. Burr is running the Petticoat mill, crushing custom rock, with results that astonish every one.

Railroad Flat.—Cor. of same: On the Bald Eagle lode, Gamble, Haines & Co. have sunk 80 feet, having had paying rock all the way down. They have run levels a hundred feet or more, with a good vein nearly the entire distance. The vein is 2½ feet in width, and 150 tons of the best quality of rock are piled up for crushing. Free gold can be seen in the ore, without a glass....The Wet Gulch Co. are still taking out rich rock. The extensions of several prominent mines are turning out well. Sinking deeper is all that is required.... In Independence, Sundermyer & Co. are driving things ahead....Reynolds & Co. are washing everything before them.

New Mill.—Amador *Ledger*, 21st: Mr. Knight, of Sutter Creek, has commenced the erection of a new mill at the Gwin mine, in Calaveras county.

DEL NORTE COUNTY.

A Nugget.—Yreka *Union*, 20th: A couple of miners on Indian creek took out, one day last week, a chunk of gold weighing 12 ounces. Miners generally in that vicinity are represented as doing well.

NEVADA COUNTY.

Pennsylvania.—*Transcript*, 18th: This mine, so long idle, is to be worked again, having been leased by the Bank of Nevada County to J. H. Helm.

Red Diamond.—This company, at the Cascades, on Deer creek, is running a tunnel through the bed-rock to reach the channel, which they propose to work by drifting. The ground prospects well.

Orleans.—Same of 19th: The first crushing, taken out 30 feet below the surface, yielded $22 per ton. They have had a crushing of nine tons from 60 feet below the surface, which paid $42 per ton. The ledge is of good size and better as they sink. We understand arrangements will soon be made for putting machinery upon the mine.

Scott's Flat.—Same of 22d: The hydraulic claims are pushed vigorously. They have plenty of water. Owing to the shortness of the season the miners are making the most of their time, running day and night.

Graniteville.—At the South Fork, Morris & Co. in a gravel claim are making from $12 to $14 per day to the hand....A German company is at work on the Baron ledge. They have expended upwards of $20,000 in prospecting....A new gravel claim has been opened between Graniteville and South Fork, which prospects very well....At Bowman's Ranch, the North Bloomfield Co. are rafting timber down to their dam.

Town Talk.—Grass Valley *Union*, 17th: The clean-up, after two weeks' run, shows well. The sum of $2,000 was realized, and the expense was $600.

West Eureka.—Same of 19th: The shaft is down 230 feet on the incline. A contract is to be let on Saturday to sink 100 feet deeper.

Eureka.—Same of 22d: Yesterday the clean-up gave $12,000 for a six days' run.

Gravel Deposits.—*Gazette*, 17th: Recent discoveries on the upper portions of Diamond creek, above Omega, lead to the conclusion that large gravel deposits extend through the ridge from the headwaters of the creek to Bear Valley.

Grant Ledge.—Grass Valley *Union*, 24th: A crushing of 40 loads of rock at Perrin's mill yielded $935.95.

Union Hill Mine.—The clean-up after a run of eleven days of mine and mill, gives $10,700.

Started Up.—The Coe mine started up yesterday. All the old scores have been paid off, and the new management starts in with an open field.

The Pittsburg.—*Transcript*, 24th: The rock averages $35 per ton. We learn that the result of last month's clean-up was $20,000. They give employment to over 100 men, and their expenses are $8,000 per month, leaving a clear profit of about $12,000.

Graniteville.—Cor. of *Gazette*, 23d: Black & Young's tunnel will soon be finished. The mine employs 30 men.

The Jim mine has been run all winter. The main shaft is down 300 feet, showing a ledge all the way from two to three feet thick. The rock pays $15 a ton.

The Dillon promises fair. In all probability there will be hoisting works put up this summer.

The Norfolk & Mohawk will soon be started up. The company intend sinking deeper and drifting.

The Birchville will soon start their incline down for another level. The ledge is two feet thick and pays $20 per ton.

PLACER COUNTY.

Ophir.—*Stars and Stripes*, 19th: The mine worked by R. G. Green and Mr. Lovely is paying well. One quartz boulder, weighing one hundred and fifty pounds, contained $250. The "Good Friday" is still worked with success by Cowan & Co., lessees. The "St. Patrick" promises a large dividend. The land owned by Andy Poland, known as the "Shed," was recently sold to Chinamen for $800. They have commenced mining operations in the ravine below.

Richer Than Ever.—As our paper was going to press, we learned that a clean-up has been made of a crushing of rock from the St. Patrick. The yield was $400 per ton. A number of rich specimens were taken out. A. B. Scott, Dutch ravine, had 85 tons of rock crushed, which yielded $16 per ton. Nelson and Erskine have discovered a ledge, a quarter of a mile north of Ophir, which prospects well.

PLUMAS COUNTY.

Sawpit Flat.—Quincy *National*: The New York Co. made a partial clean-up last week of about 200 ozs. None of the other companies have made any yet. Everything bids fair for a rich season. At Washington, the claims are paying $12 per day to the hand.

SAN DIEGO COUNTY.

Los Angeles telegram, May 19th: A 12-pound piece of rock brought up to-day from the Mount Vernon, Julian district, taken out 15 feet below the surface, is admitted to be the richest specimen yet seen from the surrounding mines. About half its bulk is free gold. Favorable news continues to be received from the principal leads in the Julian district. Mount Vernon adjoins the Washington and Mary Idivia; it was discovered in February by G. L. Turner. These three ledges on sinking show a width of about five feet.

SIERRA COUNTY.

Alleghany Consolidated Co.—*Democrat*, 19th: At the present time they employ but seven picks in the breast, but these seven pay all the expenses of twenty hands, timbers, lights, blacksmithing and all other outlays. Judge Sherwood, one of the managers, informed us that he expected to work from 60 to 100 hands in the mine before the expiration of the year, and take out monthly from $15,000 to $20,000, instead of, as now, from $1,500 to $2,000.

Bald Mountain Co.—This Co. will run an 1,800-feet tunnel from their 289-feet shaft, to drain the ground and enable them to work the immense bed of gravel under the flat. The tunnel will be large enough to allow them to work mules in it.

Forest City.—The Live Yankee claim is still paying wages. It has probably yielded more gold than any other in the State.

Alleghany.—The Packard, the Hook & Bull, and the Union have done well this spring. The last is a quartz claim.

Johnston Ledge.—Jim Johnston now owns the whole 1,400 feet. He took out $1,500 with a hand mortar on the top; and now has a 60-foot tunnel which strikes the ledge at a depth of 30 feet. He thinks he has struck it again there. He has before found several rich ledges that did not pay him well, and intends to hold on to this one.

New Mill.—The Sierra Buttes Co. are erecting a new 16-stamp mill, to be run by water.

A Nugget.—One day this week Parker & Co., of Slate Castle ravine, found a nugget of $50. This is the third piece they have lately found.

Items.—*Messenger*, 21st: The Union mining claim, at Port Wine, took out last week over 300 ounces....Watson & Ift, who are prospecting the Oro claim, on the Rock creek trail, have got their tunnel in a little over 20 feet.....The North America Mining Co., at Hepsidem, have their new tunnel in over 1,400 feet, and progressing at the rate of 50 feet per week. This company is taking out good pay through the old tunnel....Whisky Diggings is very lively this spring, reminding of the flush times of '56.

SISKIYOU COUNTY.

Happy Camp.—Yreka *Union*, 20th: We learn that the miners are generally doing well. Ambrose's claim is paying well, and Richardson's is supposed to be.

Sale.—E. Steele, has sold his "Steamboat" claim. The purchasers are Wm. Murray and Wm. Henry. We understand the amount to be paid is $40,000.

TRINITY COUNTY.

Dutton Creek.—*Journal*, 20th: The ditch is completed and the water turned in, but there will be a small head this summer. Dixon, Hurst & Co. have expended $1,000 in putting up a hydraulic. They have more than 200 feet of pressure.

Lower Trinity.—Hinds & Flynn are running a tunnel into the high peak opposite Big Flat, and have already found four or five feet of gravel containing gold. There are indications that they have struck an old river channel 500 feet above the present level of Trinity.

Northfork.—R. J. Holmes thought he would try a pan in his drifting claim the other day, and got $50. Holmes is used to it. Bill Ritterbush is cleaning up his winter's work. "Boys," says Bill, "its the first time I've been out of debt since I've lived at Northfork."

The Boy Miners.—The Gilzean boys at Cañon creek are still pegging away and doing better than the average of miners. They make about $60 per week—two boys 12 years old.

Minersville.—Little Mule creek is paying well, considerable coarse gold having been taken out. One specimen weighed four ounces, and another two and one-half.

The Prospects.—There will be more gold dust taken out this season than during the last.

Taylor's Flat.—B. C. Wattles writes that he has struck it big.

Arizona.

Big Bug.—Prescott *Miner*, May 7th: The mill is making a long run. A clean-up will soon be made.

Walker District.—The Eureka mill is producing bullion. A furnace to roast the sulphurets is in full blast....Last week, C. Y. Shelton rocked out of 800 pounds of decomposed matter from the Vernon lode $[illegible]6. He thinks the rock will pay $300 by mill process....The Accidental is yielding rich ore.

Hassayampa.—At the Sterling, Mr. Beseler is experimenting with the tailings. The placer miners are making fair wages.

Walnut Grove.—Fred Henry and others have been finding more rich ledges....Collier and Case arrived from Turkey creek with several sacks of ore from the Goodwin mine. They are to send some to San Francisco to have it tested. They will also try some of it here.

Wickenburg.—Vulture Co's 40-stamp mill running and paying, and lode looking well.

Castle Dome—Letter from Arizona City: The Butterfield Bros. and Jack Hamilton have opened two or three mines that yield argentiferous galena, about 40 to 60 per cent. lead, and from $40 to $60 per ton in silver. The ore is sold to Selby & Co. From 400 to 500 tons will be shipped during the spring. Dr. Phillips is prospecting a ledge at Eureka for a New York Co. Some 10 or 15 arastras are running at the old Picacho placer mines. The Cormorant Co., at Las Flores, are down 150 feet, and are troubled with water. Their mill will be started up soon.

Colorado.

Seaton Lode.—Central City *Herald*, May 18th: Mr. Topping is working on an 18-inch vein of good ore, at a depth of 60 feet. At a depth of 200 feet he is drifting on a good vein. The ore averages 200 ounces.

Old Mills Renovated.—The Lexington 24-stamp mill, which has been leased by Sulliven & Co., will start up on Tuesday. It has been thoroughly renovated. We hear of several other old mills which are to be overhauled and set to work.

Items.—*Register*, 18th: The engine on the Gilpin & Coaley mine will be started to-day for the first time....Mr. Hardesty has started his new 18-stamp mill in Nevada district....Frank Cramer is running his arastra on Coyote ore that shows free gold in almost every piece....Scott & Converse have 200 tons Freeland ore on dump. ....The Steil mill in Empire will soon start up....Thirty tons first-class Equator ore, shipped to Newark, assayed 800 ounces of silver per ton; 550 tons second-class assayed 137 ounces per ton. A test of third-class gave $43 per ton....Chas. H. Martin and Mr. Peters—a Freiberg graduate—have leased the mill and mine of the Fairmount Co., in Hukill gulch, for one year.

California Gulch.—Thos. Starr cleaned up his ground-sluice 10 days since, and realized over 25 ounces of fine gold—making 135 ounces since December.

Terrible Mine.—Approximate number of tons treated: First-class, 245; second-class, 225; third-class, 120; making a total of 590 tons, which have yielded $240,000—an average of $407 per ton. In addition, Clark & Co. and the Clark S. M. Co. have the estimated amount of 2,000 tons of second and third-class ore in the dump.

Idaho.

Golden Chariot.—*Avalanche*, May 14th: The ore house is full of quartz, and large quantities are piled outside. The richest is put in sacks. The greater portion now comes from the fourth level. In many places we were able to see black lumps of silver and particles of gold glistening in the light of the candle.

Ida Elmore.—There is about 200 tons of ore in the shute. The main shaft is 415 feet deep. Most of the work is now in the fifth level, where, for 100 feet, the vein is four feet in width.

Items.—Corduroy looks well. Work on the Peck & Porter will be resumed next week. France & Co. are taking out good ore from the Baxter. The Empire will erect a whim. There is a large quantity of ore ready for hauling at the Poorman. By the first of next month they expect to have 700 tons. The Bruce Bros. have purchased the old dump pile at the Oro Fino, and are sluicing it. P. McMahon is washing out the old Silver Cord dump.

Placers.—Not many clean-ups have been made, but we hear good reports from Slaughterhouse, Jacobs and Blue gulches. Miners in Wagontown are representing their claims. Florida mountain placers are worked night and day. The hydraulics are at work. Just before going to press a report of a rich strike comes from Florida mountain.

Flint.—The yield of Leviathan ore was $197 per ton, not $150 as stated. Rising Star will soon resume operations. Astor worked $168 per ton.

Snake River Mines.—One thing is now certain, there are very extensive moderate diggings along the river, above and below the great falls, that will last for many years.

Montana.

Silver Star.—Virginia City *Times*, May 14th: The Clipper lode is ahead of anything we have heard of. John Bryant from eight tons of ore in one week, on a single arastra and one stamp propelled by water, brought up 48 ounces of gold; assay value, $13 per ounce, equal to $624 in coin.

Summit.—Same of 16th: The How mill will start up to day on ore of the Chickamung. The McCluro mill will be started soon to try the barrel process on the How tunnel. Work on the leads and gulch claims of the district is progressing satisfactorily.

Items.—The Parker-Williams Co. are at work. The Highland Flume Co. expect to realize a good many thousand dollars the coming season. The Pine Grove Fluming Co. have expended $20,000, but are sanguine of a large paying yield. Southmayde & Hall are taking out gold in paying quantities. Spring gulch has paid from $5 to $7 per day to the hand. The drawback now is a scarcity of water. Rositer, Duncan & Co. are running the Frenchtown flume with success.

Outlook.—*New North-West*, May 13th: The bullion product of the placer mines this season will far exceed that of any previous year, and not fall far short, under any circumstances, of $20,000,000. Of this, Deer Lodge is good for $9,000,000 or $10,000,000, the Cedar mines $2,000,000 to $4,000,000; Beaverhead and Madison $3,000,000, and Lewis & Clark, Jefferson and Meagor $4,000,000. We found this belief upon former yields; the supply of water, unequalled for three years; the new mines opened; the ditches brought into older camps; the vigorous use of all facilities and the heavy addition to the laboring force of the Territory by immigration. Aside from Cedar creek, where work is retarded for the time being by excessive water, there is scarce an idle man in the Territory. Money is already becoming plentiful in the camps.

Blackfoot.—Every thing is lively. The ditches are full of water, and likely to keep so during the summer. Sixteen claims on Ophir bar, below Blackfoot, are paying from $8 to $18 per day. Above, six claims are worked with good results. On Carpenter'e Bar, Prairie Gulch, Stone Breaker and Snow Shoe, minere are doing well.

Philipsburg.—Two furnaces for emelting are nearly completed. Their success will, it is expected, give impulse to half a dozen other enterprises.

Cedar Creek.—The rush to Cedar etill continues, although it is well known that at present not one in ten can find employment on account of the high water.

Nevada.

COPE DISTRICT.

Mountain City.—Cor. Elko *Independent*, May 18th: A new district, 12 miles north, is known by the name of Fairweather. Most of the veins are of the base metal order, carrying from $30 to $50 in silver to the ton. The mill is running on Argenta ore and paying well. In the mine they are working 25 hands. The company ehipped to-day 5,000 pounds choice ore. Times are improving. Mr. Norton will have his mill running within 60 days. He has the promise of 1,000 tons of ore from the Argenta and Crescent mines.

ESMERALDA.

Dunderberg.—Carson *Appeal*, 21st: This mine is likely to prove one of the best. One ton of average rock worked in Aurora, a few days since, yielded $33, mostly gold. Some assays of ore from same drift, ehowed $1,800 to the ton, $300 of which was in silver.

REESE RIVER.

Magnolia Mine.—*Reveille*, 19th: W. H. Clark ie having the hoistings works overhauled, and operations will be resumed in a few days.

Metacom Mine.—The machinery some years since erected on the imaginary mine "Great Republic," has been bought by Mr. John Howell, who will place it upon the Metacom.

Strike.—A strike of rich ore wae made in the Buel North Star mine a couple of days ago.

WASHOE.

Yellow Jacket.—Gold Hill *News*, May 21st: Thie mine is yielding better than for many months. At the 900-foot level the body of ore recently developed is proving extensive. The daily yield of the mine is 360 tons.

Hale & Norcross.—The ore body at the lowest level already yields 130 tons per day of first-class ore, and the other levels some 60 more.

Occidental.—The connection of the lower tunnel with the winze will be made in three Weeks, at the present rate of progress.

Gould & Curry.—A new development of extra good ore at the 200-foot level in the old workings has caused a rise in the stock, but the extent is thought to be limited. The yield has decreased, being now 60 tons per day; average assay, $50.

Belcher.—Yielding 70 tons per day. Cross-cutting near the south line at the 730 foot level shows nothing encouraging.

Ophir.—Nothing encouraging at the upper levels. What pay-ore yield there was from the south shaft has fallen off materially.

Crown Point—The sinking of the incline from the 1,000-foot station is progressing, and 60 tons per day of low-grade ore is yielded from the upper levels.

Overman.—Daily yield 135 tons, from the 500 and the 226 foot levels. The ore paye well.

Daney.—Some fair ore is developed, and 30 tons accumulated on the dump. It will mill nearly $20

Virginia Consolidated.—Drift was 365 feet in from the ehaft. The rock is hard, but good progress is made.

Chollar-Potosi.—Daily yield 155 tons. Belvidere shows improvement.

Sierra Nevada.—Both mill and mine running at the same regular rate.

Hope.—*Enterprise*, 22d: About 40 tons has been the daily yield. Thirty-three tons have been worked in the company's mills, showing an average of $20. Everything progresses favorably.

Bullion.—The work of opening on the fifth level by driving north is diligently prosecuted.

Sutro Tunnel.—Less progress has been made during the past week. There is no increase in the volume of water. The tunnel is in 1,094 feet.

WHITE PINE.

Bullion Accumulation.—*News:* The Alsop Smelting Co. has 130 tons of bullion on hand, and other furnaces will probably swell the amount piled up to over 200 tons. Transportation for ore also is needed. The Erie and Elko (base) have each a contract with San Francisco parties to furnish 400 tons. These things suggest a railroad to Elko. Furnaces would be erected at once to turn out 100 tons daily. The average yield of the base ores is 50 per cent. of bullion. A later date of same says a meeting ie appointed to discuss the thing, and the citizens enter heartily into the matter.

Bullion shipments for week ending 16th, foot up $37,028.31—of which, $25,181.62 went West, and $11,846.69 went East.

Items—Silver Wedge has 200 tons ore on dump, and will lease a mill. Ore assays $620....Four Aces shows good ore in quantity....Hemlock and Wabash yields one ton daily to each man employed.... Davis mine has flattering prospects....Base Metal Consolidation ore assays $290—an average specimen from the dump....The White Pine Smelting Works are building another furnace....Mount Joy yields very rich ore from a 2-foot vein....Elko main shaft is down 40 feet....Trench mine is turning out ore that smelts $2,500 in silver to the ton.

Outside Districts.—In Cooper, the shaft of the Rappahannock is down 44 feet, at which level the ledge has been found to be 40 feet wide—28 feet of good milling ore. The ore is easily broken down. Gen. Grant has between three and four feet of good milling ore, at a depth of ten feet. Assays go above $200 to the ton. The Mollie Rutter has 75 tons of high-grade ore on dump, and commenced to ship to the Parsons mill at Silver Park. ....Three thousand pounds of ore from the Great Eastern mine in Patterson district, worked at the Big Smoky mill, gave a yield of $212 to the ton....Ely district sent in four bars of bullion, a few days since, valued at $1,600....Reports from Kern are favorable. The miners will develop extensively this season. New discoveries are continually making.

New Mexico.

Ute Creek.—*Press and Telegraph*, May 14th: The Montezuma mill has again shut down for eome reason, after a three days' run, cleaning up 25 ounces of retorted gold. The Atzec mill is at work, with moderate returns.

Grouse Gulch.—Pollock's and Bower's claims are averaging $15 per day to the man.

Items.—A new cut has been made near the Mereno by Little & Co. that pays $7 to the man, ground sluicing....At Orleans Flat and Last Chance two claims are being worked with large returne....On Willow gulch the pay is good, but the miners have no water....There is a fair supply of water on Spanish bar....The Humbug gulch folks have everything in readiness.

Oregon.

Baker City.—The mining season has opened brisk in Baker county. About $80,000 in gold dust and bullion was shipped, for the month ending May 10th. Water was plenty and claims paying well. One nugget worth $800 was taken out.

San Francisco Mining Stock Market.

The business of the Stock Board continues very much in the same apathetic condition as reported for some time past, the inactivity coming principally from the lack of legitimate dealers, as well as the absence of any very promising developments in the various mines, which, in most instances, give speculators an opportunity to engage in remunerative operations. Sales of a few leading stocks show a material recession, as compared with the previous week, while the majority have been quite well maintained. Transactions in three or four White Pine stocks have been free, obtaining very uniform rates.

Hale & Norcross—has not been active, though some improvement is apparent. During the week ending May 21st, the ore product of the mine has been as follows: 175 level, 301 tons; 300 level, 46½; 325 level, 90; sixth station level, 113½; and seventh station level, 1,147½—total, 1,698½ tons. The seventh level, both north and south, shows no change in the quality or width of the ore, and in breasting on the second floor, a few feet north of the shaft, they found the ore the same quality and the vein the same uniform width as on the floor below. On the 21st, they forwarded $50,640 in bullion to the office in this city. The aggregate bullion returns for the month of April foot up $125,849 against $107,057 in March, $145,203 in February, and $188,334 in January.

Chollar-Potosi—was in the market to a moderate extent, at uniform rates. For the week ending May 20th, the ore-yield amounted to 1,150 tons; the assay from car-samples showing $19 20 to the ton. The south portion of the mine exhibits some improvement, the ore coming down to the Potosi Tunnel, with prospects of extending far below. On the eighteenth floor, being the most southerly point, the ore is said to be about fifteen feet wide. At the first station of the New Shaft, 22 feet have been added to the "raise," making a total of 80 feet from the track floor. On the 20th inst. they sent forward $27,130 in bullion. A letter of the 24th states "that the south end of the mine continues good, and where the Potosi Tunnel intersects the body from above, it is about 250 feet from the surface."

Gould & Curry—continues to recede, under the usual sales. For the week ending May 21st, 416½ tons were extracted, showing an average assay-value of $40 48 per ton. No change of importance in the mine.——Kentuck has also changed hands at lower figures. During the week ending May 21st, 240½ tons were extracted, valued at $4,302—equal to $17 88 per ton.——Crown Point, under rather light sales, is lower. For the week ending May 20th, 181½ tons of ore were mined, showing a 65-per-cent. assay value of $3,196, or $17 51 per ton.

Belcher—has been in less demand than the previous week, selling at nearly the same figures. On the 23d inst., 56 feet above the 262 level, in drifting south from the "raise," they encountered a body of ore about eight feet thick, which assays $37 87 to the ton, and promises to be of some extent.——Imperial sold to a small extent at even rates. On the 24th inst., the winze had attained a depth of 44 feet, showing no particular change. Spots of ore continue to be scattered over the bottom of the winze.——Overman sent down $11,400 in crude bullion on the 23d inst.——Ophir was in the market to a less extent than last week. On May 24th, the Superintendent reported as follows: At shaft No. 1 soft ground made its appearance in the main drift, composed of a mixture of lime and porphyry. Both of the south-west drifts are progressing well, showing no change in amount of water.——Original Hidden Treasure (W. P.) sent forward $43,600 in bullion for May account up to the 24th inst.—*Commercial Herald.*

The Los Angeles and San Pedro Railroad investigation seems to ehow badly for those who had the management. Public aid to the amount of $225,000 was given for the road, which is nineteen miles long. With ewindling contracts and illegal purchases the city and county are now brought into debt on their stock, and assessments are demanded to cover the deficiency. The investigating committee appointed by the city charge the management with fraud, and advise that suit be brought to declare void the stock issued and to recover the money already paid thereon.

◆

Corinne is erecting water works for supplying its inhabitants with thie necessary article. The reservoir is built, the steam power is ready, and the pipes have been ordered in Chicago. Good for Corinne.

Bancroft's Guide.—The May number of thie guide for travelers by railway, stage and steam navigation in the Pacific States, hae just been received. This is the largest and most complete publication of the kind on the coast. Such aids are a necessity to travelers, who do not wish to journey blindly, and save the possessor much more than their cost in avoiding anxiety and labor of body and spirit reeulting otherwise from the neccessity of asking numerous questions and receiving too often rude replies. The book in question contains, however, many other interesting facts and descriptions. For sale by A. L. Bancroft & Co., 721 Market street, from whom we have also received, just before going to press, "Lothair," a novel by Disraeli, which will be noticed next week.

◆

Another mining excitement at San Diego is reported, caused by the report of wonderfully rich gold mines in Lower California. Specimens of very rich quartz have been brought, and nine or ten large, well defined ledges are stated to crop out in the locality whence the rock comes. A company of twelve have secured the services of the discoverer and chartered a yacht, to proceed immediately to the place. Another party is said to intend following in order to get a share of the epoils, and a third party to have started out overland for the same purpose.

◆

Washed Gravel in a Strange Place. We should like to hear something further with regard to the following, which we find in the Grass Valley *Union* of the 17th inst.: The miners in the 10th level of the Empire mine have come across a deposit of gravel which has been washed by water, at some period, until it is quite smooth. This gravel ie under the ledge and in the gouge. How much of it there is, and whether it is going to have washed gold mixed up with it, we cannot say; but we would not be surprised to hear any day of a rich strike in gravel in the depths of Ophir Hill.

◆

Another Atlantic Cable.—It is reported that a combination has been formed under the auspicee of the General Credit and Discount Company, of London, to lay a telegraph cable from England direct to Narragansett Bay, Rhode Island.

◆

The foundation work of the new hall for the Gold Hill Miners' Union is being energetically pushed forward. The building is to be 70 feet long, 39 feet wide, and one etory high.

Farming and Gardening.

COMMUNICATIONS for this department are solicited from all parts of the Pacific States and Territories.

The Interests of the Farmers.

The farmers of California are beginning to awaken to the necessity of doing something more than herding wild stock over thousands of wild acres, and of venturing all upon a single crop of grain. While repeated failures are constantly punishing such improvident ventures, the success attending intelligent and diversified farming is yearly proving the wonderful fertility of our soils, the favorable effect of our climate, the adaptability of, and the ways of adapting, the various parts of the State to a reliable, profitable and extended culture. Of the thousands of useful productions of the vegetable kingdom, California may, and should, cultivate the majority.

It is the province of a good agricultural paper to note the failures and the successes attending the industrial interests; to discover the wrong way and to advocate the right; to encourage the introduction of every useful and profitable thing; to recommend the best in material and in method, and to enter into the real interests of the producing public with honest intelligence and a spirit of enterprise equal to the age of progress now before us.

Since the SCIENTIFIC PRESS has undertaken, in connection with the other leading industrial interests of the Pacific coast, to make itself a leading agricultural journal, the encouragement that we are constantly receiving is gratifying to the proprietors, and we shall strive to merit such continued and increasing patronage by an untiring devotion to the material, practical and real interests of farming in all its diversified branches. We are aware that no one set of editors can, unassisted, make an agricultural paper all it should be. The farmers, the horticulturists, the gardeners, all who feel a liberal interest and take a proper pride in their occupations, should give the result of their experience for the general good. There is enough of diversity in soil and climate; there is room enough in our broad area of agricultural lands, and there should be numbers of interests and of useful products on this coast to furnish material for the *best agricultural paper in the world!* But unless the people, the individual farmers and culturists enter into the spirit of inquiry and discussion, the best efforts, the most ardent, determined and honest exertions of the editors can but partially meet the wants of the times. Every intelligent farmer is in possession of facts which would benefit somebody else if given to the light.

We are aware of how capitalists, through corruption and fraud, have monopolized and attempted to control much of the public lands in this State; we know that our County and State Agricultural Fairs have languished beneath selfish and partial interests, instead of growing in usefulness and power and grandeur through worth, enterprise and just and honest means; we see that middle men and rings and speculators —big and little—are seeking by deceit, by false reports, by confidence, by baseness and villainy, to defraud the farmer and pocket the profits of honest toil. But with any of these, and with all of these, we assert, we have no sympathy. We stand confidently and determinedly upon principle and right. We expect to at least enjoy the satisfaction of doing our humble duty. Upon our agricultural progress and success the other interests and the welfare and advancement of California must mainly depend.

Suffering, as we surely are, beneath an accumulation of grievous evils, social, political and speculative, staggering beneath stagnation in business, and dreading the possible turn of events, we recognize the need of honor, of integrity, of justice. No towering intellect is needed to startle the people with a panacea of marvelous power—a cure, a sudden cure, for all our woes!

We require the simple virtues upon which the real success of a people rests; the honesty that begets confidence; the legitimate enterprises that depend upon energetic and intelligent industry—not strategy and idle speculation. We require economy. We should open the avenues which selfishness, speculative greed and corruption have closed against the entrance of settlers to our agricultural lands; we should encourage the industry of our own people; we should import nothing from other lands that we can better produce at home; we should neither import nor especially encourage a class of immigrants to our shores that cannot be equalized, that cannot assimilate with us, and whose interests are not our interests.

Whatever fosters distinctions and aristocracy of money over labor is not in accordance with the true spirit and interest of American government. Every man here is a capitalist according to the extent and character of his power, whether physical strength, mental ability, educational attainments, intellectual aspirations, moral worth or mere dollars and cents, constitute that capital. It is the honest use that one makes of his capital that constitutes good; the real good to himself and to the world.

It is with the industrial classes that we hold communion. To their interests the SCIENTIFIC PRESS is devoted, as its face and its contents indicate. The business integrity and enterprise, the balance of mental and moral worth, the patriotism and pride of country, the hope and vindication, and the honor and success of our affairs all rest with the interests, material, educational and moral of our industrial citizens—our friends indeed.

The industrial interests of every community are, or should be, mutual interests, when equal law, equal rights and privileges are regarded. But any element of discord, such as slavery or its parallel, is disintegrating. We shall work faithfully for the best, hope for the best, and trust for the reward of the just and the deserving.

TO GET RID OF THE GREEN FLY, OR APHIS.—The best way to avoid attacks of the aphis upon plants is by thorough pruning—thinning the vines or bushes so that the sun, air and wind can have free access to the leaves, and thus render them uncomfortable habitations for these little pests. If, however, in spite of pruning, they will still remain, make a decoction of tobacco water—the liquid about the color of tea—and syringe the plants well; or prepare an instrument so that you can burn tobacco therein, and puff the smoke out among and under the leaves. If either plan is thoroughly carried out, you will not be likely to have much further trouble for that season.

PROFITS OF SHEEP RAISING.—To convey some idea of the profit that can be made in California by raising sheep, the Amador *Dispatch* relates the experience of a gentleman in that county who recently sheared 3,300 head of sheep, the clip averaging seven and a quarter pounds of wool per head, making a total of not far from 24,000 pounds in all, which he sold for $4,545.75. Besides this, he raised 5,325 lambs, which he considers worth $2 apiece, making a grand total realized from his sheep of $9,995.75—say $10,000. His profits, clear of expense, in the item of sheep raising, will not fall short of $8,000 for the year.

FOUR TONS OF BLACKBERRIES TO THE ACRE.—Mr. Nichols, of Alameda county, from a quarter of an acre sold a ton of blackberries, and used a large quantity in his family. Mr. Nichols believes with well skilled and proper management a man can make a good living on two acres by raising small fruit.

Flowers and their Organs.

There are many things of interest in relation to the stems, leaves and appendages of plants, with which the younger portion of our readers, and possibly many of the older ones, may not be familiar; but which are, nevertheless, of much importance to be understood. The office of the *leaves* is to put the plant in such communication with the atmosphere and the sun, as to secure the chemical action necessary for growth. How this is done will form the subject of a future article.

The onward or upward growth of a plant, in its stem or branches, usually continues until the terminal development consists of a flower bud alone, without its usually accompanying leaf bud. When that happens, as it does in a few weeks in the case of annuals, the vegetative or growing energy of the plant has usually reached its fullest development, and the reproductive principles then commence to develop the seed, preparatory to the death of the individual. It is to this particular form of development to which we propose to call the attention of the reader in the present article.

The flower of a plant is simply a short branch bearing upon its apex a collection of organs which may be considered as leaves, more or less modified in form, color and office. Flowers generally have four sets of organs; the *pistil*, occupying the center, the *stamens*, surrounding it, the *corolla*, surrounding the stamens, and the *calyx*, embracing the whole at the lower extremity.

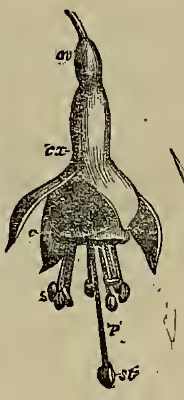

FIG. 1.

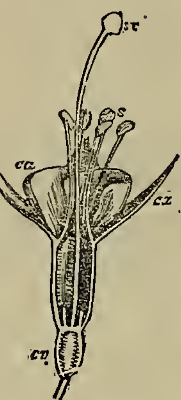

FIG. 2.

The numbers of the pistils, stamens and parts of the corolla vary greatly in different flowers. For our present purpose of illustration we have selected the fuchsia, one of the most beautiful and graceful of all cultivated plants. Fig. 1 shows a perfect flower; Fig. 2, the same in section. The different organs are correspondingly marked in both—P, pistil, *s*, stamens, *c*, corolla (sometimes called crown), and *c x* calyx, or cap.

The *pistil*, or *pistils* occupy the center of the perfect flower. They vary greatly in form, but always have at their base the seed-vessels or *ovaries (ov.* in the figures), in which are found the *ovules* (little eggs) or rudimentary seeds. In fruit-bearing plants the ovary becomes the fruit. The pistil is generally composed of two parts—the stem or tube, and the little knob shown upon its summit, which constitutes the stigma. The stigma is destitute of the outer covering or epidermis, which envelopes all other parts of the plant, while the stem or tube is hollow, as shown in Fig. 2. The object of the nakedness of the stigma, and the hollow form of the stem, will be apparent when we come to describe the mode of fertilization, which we shall do next week.

The *stamen* or *stamens*, *s* in the figures, are generally quite similar in appearance to the pistils, and are also terminated at the top by little knobs or sacks, called antlers, which, at maturity, discharge the pollen. The stamens and pistils are called the *essential* organs of the flower, because it is by the means provided in them that the seeds are produced and the plant perpetuated.

The *corolla* is usually made up of one or several series of leaves, inclosed within the calyx, and usually of some other color than green. It forms the crown or most attractive part of the flower, and is often marked with great delicacy of structure. When the corolla is divided into separate leaves they are termed *petals*. The fuchsia has four, the cultivated rose has an indefinite number; but in its natural or wild state only five.

The *calyx*, it will be noticed, is the outermost envelope. In most flowers the color of this organ is green. When it consists of several distinct leaves they are called *sepals*. In the fuchsia it is a single organ divided into four lobes.

Some flowers, as the buckwheat, have no corolla. In the grasses, which have no flowers, the calyx and corolla are represented by scale-like leaves, which subsequently form the "chaff" of the grain or grass.

In some plants the stamens and pistils are found on separate flowers; corn, the squash and melon families, and some trees (the oak and birch) are examples of this kind. In corn the stamens are on the tassels and the pistils on the silk.

Again, some plants have the stamens on one individual and the pistils on another—in such the former is known as the male plant, the latter as the female. The willow tree, the hop-vine and hemp, are examples under this head, and some varieties of the strawberry.

We are indebted for the accompanying cut to Prof. Johnson's "How Crops Grow."

We shall next week endeavor to describe, by use of an illustration, the process of the fertilization of flowers, with brief reference to hybridizing.

Farming Profits in the Foot-Hills.

Mr. J. D. Reese, residing in the foot-hills of Placer county, has furnished the following interesting items to the Auburn *Stars and Stripes:* Mr. R. has a vineyard and orchard of peaches, apples and pears, covering seven acres of ground, the soil of which most people would think too poor to justify the belief that it would produce black-eyed peas. The gross proceeds of his crop of last year from the seven acres sold in market amounted to $2,100; cost of cultivation, picking and marketing, $250; net proceeds, $1,850.

He also furnished the following figures detailing the average product of his vines, ascertained by actual weighing:

Common Los Angeles, per vine	30 lbs.
White Cerian, per vine	60 lbs.
Muscat, per vine	60 lbs.
Malsga, per vine	60 lbs.
Black Vinsindall, per vine	60 lbs.

Eight hundred of these vines may be planted on an acre of land, and, estimating thirty pounds to the vine at the age of five years—at one cent a pound—the product would be the almost incredible sum of $240 per acre. Does any one doubt that lands capable of producing so much are worth two dollars and fifty cents per acre, or that they will not soon be in demand?

THE ALAMEDA FARMERS' CLUB—GOPHERS AND SQUIRRELS.—At a late meeting of the Farmers' Club of Alameda county the subject of killing gophers and squirrels was discussed, and it was unanimously resolved that strychnine, administered in soaked barley, was the most effectual way to kill rodents of all kinds. Phosphorus was voted as dangerous and not fatal in its effects.

COLLEGE OF AGRICULTURE.—The Building Committee of the Board of Regents of the University of California have got so far along in their labors as to be prepared receive bids for the erection to of the Agricultural College building at Berkeley.

A Model Fruit Farm.

Between the town of Santa Clara and the bay, I chanced, in my travels, upon the small-fruit farm of Mr. J. A. Wilcox. This gentleman has some sixty acres in small fruits, all planted within two years, which he calls his experimental gardens; not that it is an experiment in this State or county to cultivate such fruits, nor yet that he lacks experience in such culture. One of the original fruit-growers in Fruit Vale, Alameda county, he has now settled on what he considers a superior location; has procured a great variety of fruits, some of them from the East, at great expense; and by an impartial trial and comparison he expects to arrive at the relative merits of every variety. He designs also to experiment in the various methods of training, cultivation, irrigation, etc.

With a mind singularly clear of mere theories, a large accumulation of facts and data from the experience of years in California, has only created a relish for more on which to correctly form opinions.

It is the apparent nature of most men to be very positive in theory, in spite of truth, and to regard facts as illusions, rather than yield a point; but it is refreshing to meet, occasionally, one that has the modesty to admit the superiority of every principle over inferences. With much information as to the policy to pursue for profit, as well as for pleasure and knowledge, his designs exhibit a system and an economy quite commendable. Nowhere in my journeyings have I been more agreeably entertained and interested than while accompanying Mr. Wilcox over his grounds.

Of currants and gooseberries he has out some 30,000 of each, fine plants, making a beautiful showing of fruit for plants so young. The Houghton Seedling—the well known American gooseberry—he has the most of, and considers that the only reliable variety.

The cherry currant and the *Fertile de Paluau* he is testing side by side. He has the most confidence in the former, though many in this county favor the latter as the best. His 40-acre blackberry field he takes special pride in, and with good reason. The Lawton, Kittertinny and Early Wilson varieties make a splendid show. His system of training, though somewhat varied, is generally low, branching and shortening-in. He cultivates with horse but one way, and occupies the space in the rows by close planting. His soil is a fine, rich, dark adobe, and it is, in my opinion, not so suitable for small fruits as a lighter alluvial soil would be. But he plants on back-furrowed ridges, which will undoubtedly tend to correct the heavy and, in dry times, contracting and cracking tendency of such soil. S. H. HERRING.

[The balance of our correspondent's notice of Mr. Wilcox's Model Fruit Farm will appear next week.]

THE FECUNDITY OF FISHES IS ENORMOUS. Mr. C. G. Atkins, Commissioner of Fisheries of Maine, has been making some calculations of this subject. By examination he found that a perch, weighing 3¼ozs. produced 9,943 eggs at one litter, a river smelt, weighing 2 ozs., 25,141 eggs; a fresh water smelt, weighing 10 ozs., 80,000 eggs. Sea or river salmon (migratory) yield on an average a little less than 1,000 eggs for each pound weight, and shad not less than 50,000 per fish. Taking a salmon (one of the least fecundative of fishes, but whose productive powers and rate of growth are better known than those of most other species) and assuming that a female will at the age of four years produce 7,000 eggs at one spawning (a very moderate estimate), that all the eggs hatch, that all the young arrive at maturity and that the sexes are equally divided, he finds the following results: The first brood, at the end of four years, numbers 7,000; the second brood at eight years will number 24,500,000. At the end of 12 years there are 85,750,000,000 fish; and the fourth brood, at the end of sixteen years, numbers 300,125,000,000,000—salmon enough to cover the whole state of Maine a hundred feet deep.

AN agricultural school has been lately established at Milan, Italy. The city and the general government contribute for its support a large sum annually, with a goodly amount to start the institution.

A New Pursuit Badly Needed.

There are in the United States hardly less than twenty millions of persons interested in and subsisting by agriculture The number of farms can fall little short of four millions, and they are rapidly increasing in number through the breaking up of Southern "planteries" and far western ranches. The census of 1880, if properly taken, will probably return not less than four millions of farms, whereof three-fourths will range from forty to three hundred and sixty acres in area; most of them from eighty to one hundred and sixty acres.

The men who own and work these farms have generally received a common-school education; not a tithe of them have gone further. They know how to plow, to sow, or plant, to till and harvest, as well as their grandfathers did—some of them better—but their average crops are no heavier than those of eighty years ago—nay; they are probably lighter, if we regard only the region which has been so many years in cultivation, because of the exhaustion of the soil. Last year, because of the drouth, Virginia and the Carolinas produced less than half their average corn crop of eighty years ago.

Those years have witnessed signal progress in agricultural implements and machinery. Our farms are seeded and tilled—above all, our crops are cut and housed—with far less labor than of old. Apart from this, the great body of our farmers stand where their grandfathers did, unheeding that the world has moved on. An excess of water long since converted their level lands into sour bogs and stagnant ferns; and thus they still remain. Rain falls capriciously, and for the most part at seasons when they least need it, leaving the uplands parched and thirsty, throughout weeks and even months, when their need of moisture is greatest. The water that is badly needed in July and August, runs off unheeded and worse than useless in spring, because it carries away the best ingredients of the soil. In short, while civilization has stamped its living impress on our manufactures, commerce and navigation, our agriculture remains too generally in the rude, barbarian stage which it should have long since outgrown.

A chief need of our times is a class of thoroughly capable, qualified practical agricultural engineers. They should be ready to give a reason for the faith that is in them, but they should be known as workers, rather than as talkers. Each of them should be able, after thoroughly traversing an average farm, to tell its owner how to increase the product not less than one hundred dollars per annum henceforth, by a present outlay of five hundred dollars. He should be able to say, where the draining of its soil should begin, and in what order field after field should be subjected to this renovating process. He should be able to point out the ravines and steep acclivities or rocky ridges that should be planted to choice timber, and the points at which water should be held back in spring, to irrigate and fertilize the lower slopes and vales during the scorching blasts of summer. He should be able to decide at a glance, just where buildings and yards should be located, and to give a lucid reason for his choice. One such man in each rural county would immensely increase the annual product of our fields, the average recompense of our farmer's efforts, while slowly creating a useful career for himself. When shall we have him? and how shall he be distinguished from the swarm of quacks and shallow pretenders who disgust our discerning farmers by loud talk made up of conceit and emptiness?—*H. G. in the Technologist.*

LOOK TO YOUR HORSES' FEET.—Few men who handle horses give proper attention to their feet and legs. Especially is this the case on farms. Much time is spent of a morning rubbing, brushing and smoothing the hair on the sides and hips, but it is seldom the feet are examined and properly cared for. The feet of a horse need quite as much attention as the body. They need more, in fact, for in one respect they are almost the entire horse. All the grooming that can be done won't avail anything, if the horse is forced to stand where his feet will be filthy. In this case the feet will become disordered, and then the legs will get badly out of fix, and with bad feet and bad legs there is not much else of the horse fit for anything. Stable prisons generally are terribly severe on the feet and legs of horses, and unless these buildings can afford a dry room, where a horse can walk around, lie down, or roll over, they are not half so healthy and comfortable to the horse as the pasture, and should be avoided by all hostlers.

What I Know of Farming—No. 19.

Soils and Fertilizers.

A farmer is a manufacturer of articles wherefrom mankind are fed and clad; his raw materials are the soil and the various substances he mingles therewith or adds thereto in order to increase its productive capacity. His art consists in transforming by cultivation crude, comparatively worthless, and even noxious, offensive materials into substances grateful to the senses, nourishing to the body, and sometimes invigorating, even strengthening to the mind.

I have heard of lands that were naturally rich enough; I never was so lucky or perchance so discerning as to find them. Yet I have seen Illinois bottoms whereof I was assured that the soil was fully sixteen feet deep, and a rich, black alluvium from top to bottom; and I do not question the statements made to me from personal observation that portions of the strongly alkaline plains or swale on which Salt Lake City is built, being for the first time plowed, irrigated, and sown to wheat, yielded ninety bushels of good grain per acre. I never saw, yet on evidence believe, that pioneer settlers of the Miami valley, wishing, some years after settling them, to sell their farms, advertised them as peculiarly desirable in that the barns stood over a creek or branch, which swept away the manure each winter or spring without trouble to the owner; and I have myself grown both wheat and oats that were very rank and heavy in straw, yet which fell so flat and lay so dead that the heads scarcely bore a kernel. Had I been a wiser, better farmer, I should have known how to stiffen the straw and make it do its office, in spite of wind and storm.

[And let me here say, lest I forget it in its appropriate place, that I am confident that most farmers sow grain too thickly for any but very poor land. If one thinks it necessary to scatter three bushels of oats per acre, I tell him that he should apply more manure and less seed—that land which requires three bushels of seed is not rich enough to bear oats. He might better concentrate his manure on half so much land and save two-thirds of his seed.]

I do not hold that the remarkably rich soils I have instanced needed fertilizing when first plowed; I will presume that they did not. Yet, having never yet succeeded in manuring a corn field so high that a few loads more would not (I judge) have increased the crop, I doubt whether even the richest Illinois bottoms would not yield more corn, year by year, if reinforced with the contents of a good barn-yard. And, when the first heavy crop of corn has been taken from a field, that field—no matter how deep and fertile its soil—is less rich in corn-forming elements than it was before. Just so sure as that there is no depletion or shrinkage when nothing is taken from nothing, so sure is it that something cannot be taken from something without diminishing its capacity to yield something at the next call. Rotation of crops is an excellent plan; for one may flourish on that which another has rejected; but this does not overbear Nature's inflexible exactions of so much for so much. Hence, if there ever was a field so rich that nothing could be added that would increase its productive capacity, the first exacting crop thereafter taken from it diminished that capacity and rendered a fresh application of some fertilizer desirable.

Years ago, a western man exhibited at our farmers' club a specimen of the soil of his region which was justly deemed very rich, taken from a field whereon corn has been repeatedly grown without apparent exhaustion. A chemical analysis had been made of it, which was submitted with the soil. It was claimed that nothing would improve its capacity for producing the great Illinois staple. Prof. Mapes dissented from this conclusion. "This soil," said he, "while very rich in nearly every element which enters into the composition of corn, gives barely a trace of chlorine, the base of salt. Hence, if five bushels per acre of salt be applied to that field, and it does not thereupon yield five bushels per annum more of corn, I will agree to eat the field."

Many men fertilize their poor lands only, supposing that the better can do without. I judge that to be a mistake. My rule would be to plant the poorest with such choice trees as thrive without manure, and pile the fertilizers upon the better. It seems to me plain that of two fields, one of which has a soil containing nine-tenths of the elements of the desired crop, while the other shows but one to three-tenths, it is a more hopeful and less thankless task to enrich the former than the latter. If you are required to supply to a field nearly everything that your proposed crop will withdraw from it, I do not see where the profit comes in; but if you are required to supply but a tenth, because the soil as you found it stood ready to contribute the remaining nine-tenths, it seems to me that the margin for profit is here decidedly the greater.

How many tons of earth ought a farmer to be obliged to turn over and over in order to obtain therefrom a hundred bushels of corn? Two hundred? Five hundred? A thousand? *Five* thousand? Other things being equal, no one will doubt that, if he can make the corn from one hundred tons of soil, it were better to do so than to employ five hundred or five thousand. It seems clear to my mind that, though other conditions be unequal, it is generally well to endeavor to produce the required quantity from the smaller rather than the larger area.

I fully share the average farmer's partiality for barn-yard manure in preference to most, if not all, commercial fertilizers. In my judgment, almost any farmer who has cattle, with fit shelter and winter fodder, can make fertilizers far cheaper than he can buy them. I judge that almost every farmer who has paid $100 or over for guano (for instance), might have more considerably enriched his farm by drawing muck from some convenient bog or pond into his barn-yard in August or September and carting it thence to his fields the next fall. If he can get no muck within a mile, let him cut, when they are in blossom, all the weeds that grow near him, especially by the road-side, cart them at once into his barn-yard, and there convert them into fertilizers. In autumn replace the hay-rack on the wagon or cart, and pile load after load of freshly-fallen leaves into your yard, taking them, if you may, from the sides of roads and fences, and from any place where they may have been lodged or heaped by the winds, your own wood lot excepted. Plow the turf off of any scurvy lot or road-side, and pile it into the barn-yard; nay, dig a hundred loads of pure clay, and place it there if you can get it at a small expense, and your average soil is gravelly or sandy. The farmer who is unable or reluctant to buy commercial fertilizers should apply his whole force every autumn to replenishing his barn-yard with that material which he can obtain most easily, which the trampling of his cattle may readily convert into manure. A month is too little, two months would not be too much, to devote to this good work. Some may seem obliged to postpone it to winter; but that is to run the risk of embarrassment by frost or snow, and encounter the certainty that your material will be inferior in quality, or not so well fitted to apply to grain crops the ensuing fall.

I close by reiterating my belief that no farmer ever yet impoverished himself by making too much manure or by applying too much of his own manufacture. I cannot speak so confidently of *buying* commercial fertilizers; but these I will discuss in my next.—*Horace Greeley.*

Brigham Young is making arrangements to set out 200,000 fruit trees at Salt Lake.

Notices to Correspondents.

ARTISAN, Millbrae, San Mateo county.—It would. The "inertia" of a body resists any change in its condition of rest or motion; that is, if at rest, force must be applied to move the body, or, if moving, to stop it. In practice the resistance of the atmosphere is a principal opposing influence to the progress of a body moving through the air. Were this and other obstacles removed, a body once started would ever continue in motion, and the power being continuously applied, the velocity of the body would be continuously increased.

M. S.—The "Litigant Act," to which you refer, is "an Act for the Protection of Litigants," a misnomer for an act passed by the last legislature, requiring all "legal notices" to be published in an official paper, whereby litigants, instead of being "protected," are greatly overcharged for the legal notices they are required to publish. Mining advertisements are not "legal notices," in the sense contemplated in the "Litigant Act."

UTILIZING BONES.—We shall endeavor to make reference to the communication of our Weaverville correspondent on the utilization of bones in our next issue.

ASPHALTUM ROOFING.—Asphaltum roofing, properly manufactured, is a protection against fire to a very considerable degree.

J. J.—Bull Run.—Your article was received too late for publication this week, but will appear in our next issue.

RAILROAD TIME-TABLE.—By reference to our advertising columns it will be seen that two hotel trains arrive from New York and depart from San Francisco on the Western Pacific and Central Railroads. The evening train also arrives here at an earlier hour than formerly, which is quite favorable for local and through passengers on the line, who wish to enjoy the whole evening in the city.

* * *

WE hear that the Messrs. Comer have gone into trout-breeding on a large scale. They have constructed ponds, hatching-houses, etc., at a place four miles above the town of Truckee, and have 100,000 spawn on hand. They get an abundant supply of water from the Truckee river.

* * *

WE see that the Globe Foundry at Stockton has received large orders for machinery, principally patent blowers, pipes, &c., from Salt Lake City.

Educated Mining Engineers.

It seems strange that in the present age it should be necessary to put forth a plea for education in any profession. And yet it cannot be denied that there is among our mining communities a strong prejudice against educated engineers, which finds expression in the columns of many of our interior papers, which, in most respects, are characterized by their good, sound common sense. There must, then, be some ground for this feeling, which is so directly opposed to the spirit of the age.

Those who reside any length of time in a mining camp will soon perceive what these reasons are. First, every now and then some quack appears, and with many glib words, gives himself out as a scientific man, although he may have not the least smattering of science. He talks himself into the confidence of those who are unable to detect the real from the spurious article, and after a brief career, during which he perhaps draws freely on the pockets of his victims, "sluffs away," to use Thoreau's expressive phrase, "leaving merely a grease spot," which dirties the garments of real science.

Another injury is done by persons of really good attainments in some similar profession, but who have never studied *mining*. Because they are good chemists, or perhaps well read in the geology of other lands, people expect that they will be able to give prophetic information with regard to special localities, of which they have not the slightest knowledge, and where they make a merely superficial and hurried examination.

Such men are by no means mining engineers, nor does a knowledge of chemistry alone, or of geology alone, although good as far as they go, entitle them to the name of such. Mining engineering is as much a special branch and demands as much special study as any other profession, and mining by no means deserves to be considered the last refuge of uneducated quacks, retired sea-captains or broken-down stock-speculators.

A third class is comprised of persons who, having been at a place where a good mining school exists, therefore lay claim to be considered educated men, although they may never have attended properly a single course of lectures. We know of several in this State or adjacent Territories, who set themselves up as engineers on the strength of having resided a few months or even a few years at Freiberg, where, to our personal knowledge, they have done anything but study. As everything is expected of them, they, of course, fail to satisfy expectations, and are pointed at as proofs of the folly of a scientific education.

Again, any failure of a "scientific" person, whatever his grounds for the title, is marked and remembered, while the thousands of failures of uneducated men are passed by without comment. The mistakes in any locality of one person who has studied the theory of mining is enough to prejudice all inhabitants of that place against the whole profession, while "practical" men may go on, year after year, committing the most egregious blunders, and no deduction is drawn therefrom.

The object of a mining school is not to turn out a finished engineer. This is not claimed by any thinking man. The course of study merely enables one in a few years to learn what the *practice* of long periods of time has taught the world. Theory may be considered as the condensation of practice. A purely "practical" man knows only what he has learned by his own personal experience, which must of necessity be extremely limited. A student at Freiberg, or some similar school, has the advantages of the experience of thousands of practical men, attained from the first days of mining up to the present time. Whether he profits or not by the advantages offered, depends entirely on himself. That many of the young men do not do so, is an unfortunate fact, but one which militates against themselves personally, not against the schools.

Theory and practice must go hand in hand. The young graduate of Freiberg, who has earnestly studied his profession, comes forth rich in knowledge, which will enable him to avoid many pitfalls into which he knows a host have fallen before him. But yet he has much to learn. He has still to find out how to manage men who may be placed under his charge, still to study the financial side of the profession, still to examine the particular points in the place where he may be called upon to labor. With his many advantages, however, he is enabled to make in practical life, in a short time, those advances which uneducated men can make only in the course of years. Put him in a new position, and his reasoning powers and studies, already cultivated, will show him much more quickly the why and wherefore than is possible with a man of equal powers but of less cultivation. His proper place is at first in a subordinate position, where he may learn the details, being already acquainted with the generalities.

Practical men, so-called, are all theorists to a certain extent. We have yet to find one of these, who does not have his pet theories as well as the most "scientific" individual. Their weak point is, that their theories are generally founded on too limited experience. But we never found a successful "practical" man who did not *regret his want of theoretical education*, and acknowledge that such would have been a great help to him. What more convincing practical proof of the value of education do we need than this?

Education never hurts a man for practical life. A true student is a hard-working man, and his education leads him to ever-renewed exertions. That it unfits him for practical life, is a totally wrong idea. It is only those who are too lazy to get education, who make the loafers and "door-step roosters," as our friend of the White Pine *News*, we think, calls them.

It is our endeavor to do something towards educating the practical man, who cannot go abroad for knowledge, by bringing to his notice facts and experiences of others elsewhere. And in return he can teach us very much by giving us the result of his own experience, which we will publish for the benefit of others. By an interchange of ideas and a more general dissemination of facts, each individual is personally helped in his work. For no man can labor intelligently for any length of time without learning something, getting some education, while no man can hope to make any great progress unless guided and instructed by the lessons others have been taught. Our practical men are, and must of necessity be, educated men, to a certain extent, in this sense. Far be it from us to slander them by calling them otherwise. But rather than deduce from their success the uselessness of education, it is more reasonable to conclude that they would have been more successful in their business, had they known more about it.

* * *

HOTEL AT YOSEMITE.—A grand hotel is to be built at the Yosemite Valley, facing the Bridal Veil Falls, by a company of French and English capitalists, it is said. We do not know exactly how Messrs. Hutchings & Lamon have located their claims, but suppose that the hotel will be on their land, if their title is affirmed.

* * *

THERE is a bill being considered by Congress for the construction, preservation and repair of fortifications. For this purpose it is proposed to appropriate $1,264,000, and of this amount to apply $250,000 for the forts on our bay.

THE NEW BRANCH MINT.—On Wednesday the corner-stone of the new mint was laid with appropriate ceremonies, under the auspices of the M. W. Grand Lodge of Free and Accepted Masons, in the presence of a large number of people. The oration was delivered by Judge J. H. Hardy. There was singing by a chorus of male voices, and the bands of the 12th and of the 2d artillery furnished instrumental music. The following are the names of the persons connected with the erection of the building, as contained in the list placed in the casket with other articles: Hon. George S. Boutwell, Secretary of the Treasury; Hon. Alfred B. Mullett, Supervising Architect Treasury Department; Hon. J. C. Rankin, Assistant Supervising Architect; W. P. C. Stebbins, Superintendent; Henry Baker, Clerk; Henry Eagles, Master Mechanic; John Higgings and Francis Lorondes, Contractors for Excavation; James McDevitt, Contractor for Rock and Concrete; J. C. Tobin, L. P. Myers & Co., Griffith & Co., and James Emery, Contractors for Stone; W. S. Phelps & Co., Blacksmiths; Hanscom & Co., Foundrymen, Pacific Rolling Mills Company; Thos. H. Selby & Co., Iron; G. Healy & Co., Stonecutters; Chas. C. Bromau, Sand.

* * *

THE STOCKTON SHIP CANAL.—A company has been organized to undertake the construction of this canal, which is to connect Stockton with the San Joaquin river at Venice. This is to be 14½ miles long, 150 feet wide at the top and 70 feet at the bottom, and 25 feet deep. The estimated cost of the excavation is about $1,700,000. The scheme embraces the reclamation of some 25,000 acres of swamp land; the leasing or cultivation of land acquired along the route; the building of docks, wharves and warehouses; and the maintenance of a tug-boat service. It is hoped to get aid by the private grants of land to the amount of ten to twenty thousand acres, and foreign capital will be invited to subscribe. The capital stock is fixed at $3,500,000. The Directors are: William Henry Knight (the originator of the canal project), President; Captain Thomas K. Hook, Vice-President; Charles G. Hubner, Treasurer; H. H. Bancroft and Samuel Eldridge.

* * *

COAL OIL EXPLOSION.—By the upsetting of a coal-oil lamp on the 20th inst. two young ladies of this city were so fatally injured that they died soon after. A sample of the oil has been assayed by the State Assayer, Mr. Louis Falkenau, and declared extremely dangerous, giving off inflammable vapors at 84° Fah., whereas all such oils evolving the vapors at a temperature below 100° are unfit for use. Coal-oil explosions are becoming fearfully frequent, owing to the adulterations with other dangerous mixtures. The manufacturers of these murderous compounds deserve to be tried for manslaughter. The purchaser, who buys the article for use, cannot be expected to test it, but must rely on the honesty of the seller. To allow one's greed for money to endanger the lives of people is dastardly and criminal in the highest degree.

* * *

PROPOSED RAILROAD TO HAMILTON.—Our wide-awake neighbors at White Pine held a large and enthusiastic meeting last Saturday for the purpose of taking steps towards the building of a railroad to connect that district with some point on the Central Pacific Road. A committee of six was chosen to collect and report statistics, showing the amount and kinds of freights incoming and outgoing from this and the adjoining districts.

* * *

THE WOOLEN MILLS.—It is stated that a large portion of the stock of the new woolen mills, to be erected at the Potrero, has already been taken. Great confidence is felt in the concern, which will be under the able superintendence of Mr. D. McLennan, the founder of the woolen business on this coast.

Manufacturing Spoked Wheels.

The use of iron-hubbed wheels is continually increasing, and their advantages over those with wooden hubs are being generally recognized. Especially valuable is the iron hub in our climate, and we see that it is becoming quite popular among farmers and others who have occasion to use heavy wagons. A manufacturer who, several years ago, did considerable business in this State, had his attention called to this point, and has constructed a machine for the purpose of improving the manufacture of this class of spoked wheels; and we illustrate the device as an invention of value to our coast.

The machine occupies space on two floors. At equal distances around a strong circular plate of cast iron, placed horizontally, are a number of levers, B, equal to the number of spokes to be set in the wheel, and fastened securely to the plate. The short arms of the levers, which extend towards the center, are formed into cams, which act upon sliding pins of cast iron, moving freely in a radial direction in guides. When these short arms are lowered, the pins can easily be pressed outward; when the arms are raised, the pins are thereby pressed inward, and the spokes of the wheel, which is shown in the cut, are firmly forced into place.

The longer arms of the lever are worked by means of wrought-iron rods, C, which converge downwards to a central column, D. On this column is cut a screw, on which works a nut, E, whereby the levers are all raised or lowered simultaneously, with any required power. This nut is moved by means of beveled gears and a belt with fast and loose pulleys. These, in connection with a shipper, F, and shipping rod, G, are so arranged that by throwing the belt automatically at the proper time on and off a loose pulley the motion of the nut and levers is stopped and reversed.

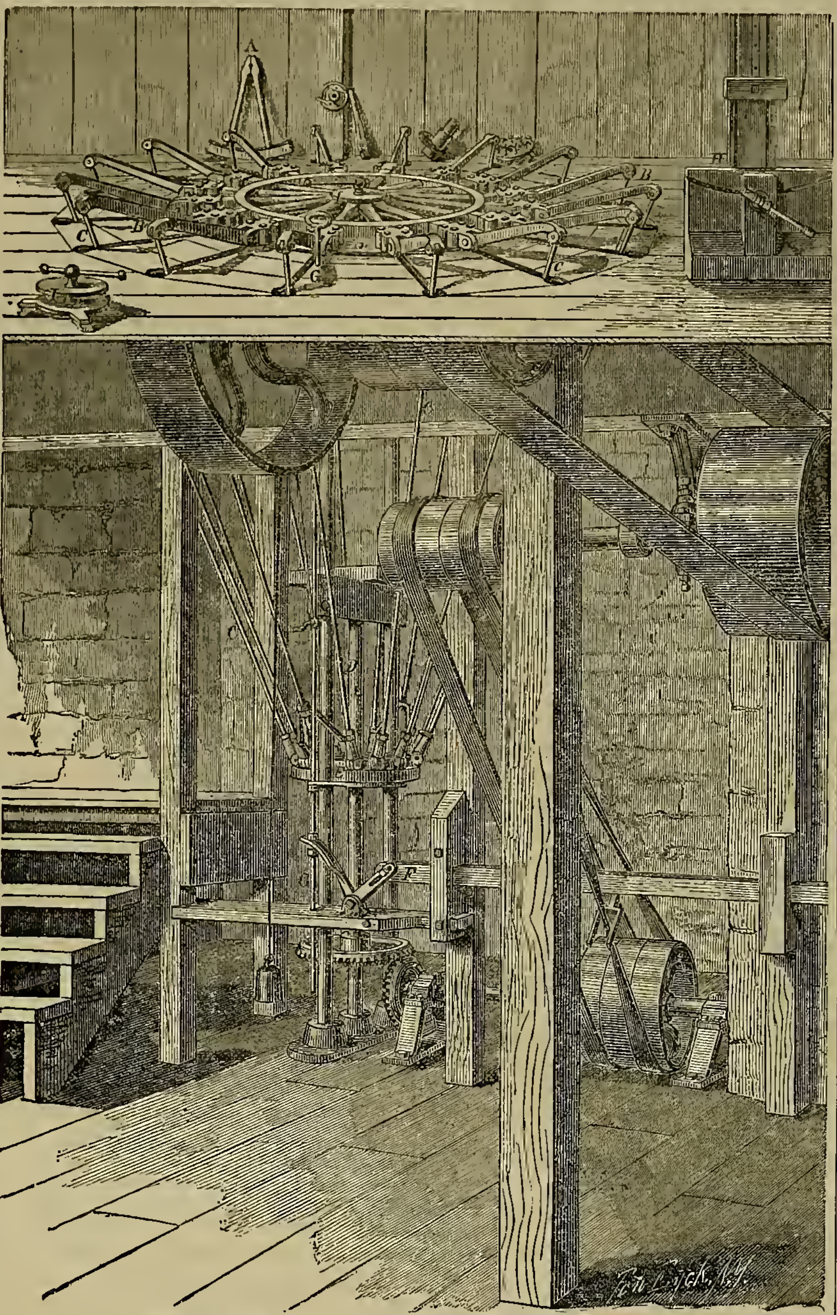
The fellies and spokes, which have been shaped and finished by machinery, are first put together by driving two spokes into a felly, one at a time, the felly being firmly held by a vise, H, specially constructed to prevent the splitting of the felly or the twisting of the spoke. Eight fellies with their sixteen spokes are then placed in the press, and here temporary hub-plates, I, one above and one below, with a powerful screw in their center, hold the ends of all the spokes in the plane of the circular plate, while undergoing the press of the levers. This pressure is put on till the joints of the fellies close up, its extent being ascertained by marks made previously and subsequently. The hubs are firmly bolted together while the wheel is in the press and hold the spokes securely. The fellies spring apart a little, but only a little; and this is remedied by the tire.

The great point is the thorough compactness of the hub-end of the spoke in a wheel made in this manner. Moreover, by using a much greater pressure than the wheel will ever be subjected to in practice, the spoke and felly are so compacted that, if the tire is properly set, it will remain tight until worn out, it is claimed. The whole process is so simple that a workman can learn in a very short time to operate the machine, and one man with an assistant can easily put together six sets of four wheels each in from six to seven hours.

With wooden hubs the spokes are weakened at the hub, where they need to be strongest, while with iron hubs this is reversed. A wheel made on this plan can be subjected to any required pressure, will [illegible] it is claimed, and is turned out perfectly round and true. We see no reasons why such wheels should not prove very superior in our State, with our long seasons of continued wet and of continued dry weather, and where often the wagons are left out the whole time in the open air.

We learn that Messrs. Treadwell & Co., of this city, have these wheels, which may be seen on Hoadley's portable engine, and have ordered a large lot of engine wagons from the inventor, who says that his process lessens the cost of manufacture over fifty per cent.

Any communications with regard to obtaining further particulars may be addressed to the patentee, E. A. Archibald, Methuen, Mass.



MACHINE FOR THE MANUFACTURE OF IRON-HUB WHEELS.

* * *

Last December a party left this city for Cocos Island to get possession of a hidden treasure which their guide knew all about. Having performed a large amount of labor in digging up the earth for seventeen days, they lost confidence in their conductor, and have now returned. Having become accustomed to handle the shovel, they have received at least this much benefit from their trip.

* * *

An Important Move.—The *National Gazette* of Nevada City has been informed that the immense slide on the claim of Mr. Ashburne, of Scotch Flat, is still moving forward as regularly as a glacier. The mass thus moving is about 2,000 feet long by 500 feet wide; depth unknown. The moving mass occupies about twenty-four [illegible]

Patents and Inventions.

A Full List of Patents Issued to Pacific Coast Inventors.

[From Official Reports to DEWEY & CO., U. S. and Foreign Patent Agents, and Publishers of the Scientific Press.]

For the Week Ending May 17th.

Thorough-Brace Spring.—John Goller, Los Angeles, Cal.
Manufacture of Illuminating Gas.—Edmund P. McCarthy, San Francisco, Cal.
Breech-Loading Ordnance.—Abiather Fales Potter, San Francisco, Cal.
Machine for Jointing Staves.—John Westley Alesworth, Santa Cruz, Cal.
Anchor.—Albert H. Law, San Francisco, Cal.
Frame for Street Lamps, Etc.—Jacob Radston, San Francisco, Cal.

Note.—Copies of U. S. and Foreign Patents furnished by Dewey & Co., in the shortest time possible (by telegraph or otherwise), at the lowest rates. All patent business for Pacific coast inventors transacted with greater security and in much less time than by any other agency.

* * *

Gold Saving Apparatus.—The Grass Valley *Union* speaks of two recent inventions, now being tried at that place, for saving the gold in the sand which is ordinarily allowed to run into the creek. One is described as being the application of millstones to this purpose, and is said to work very well, saving large amounts of the precious metal which have been previously thrown away. We are glad to see that more attention is being given in this direction. There is nothing new, however, in using millstones for pulverizing ore.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co's Scientific Press American and Foreign Patent Agency, the following are worthy of mention:

Improved Anchor.—A. H. Law, S. F. This improvement relates to that class of anchors in which the arms or flukes revolve simultaneously from side to side of the shank, turning in the crown piece or end of the shank. It consists, first, in an improved device for stopping the revolutions of the flukes when they have turned to the proper position for taking hold of the ground; secondly, in constructing the shank in two pieces and joining them together; thirdly, in an improved construction of the flukes or holding palms. The arrangement permits the flukes to take a deeper hold on the ground by shortening the length of the shank; and when the strain is on the cable it will stand at an angle to the shank and consequently give a downward pull on the flukes and not a lifting pull, as is the case where a solid shank is used. There is an arrangement of chains which serves to hold upon the main portion of the anchor, in case the bolt, uniting the two shank pieces, should break, and to prevent the vessel from being turned loose. There are links constructed so as to serve in securing the anchor to the cat-head, as a means of raising it to a more convenient position; and the danger of fouling is avoided, as there are no projections to hinder the free movement of the cable.

Manufacture of Illuminating Gas.—E. P. McCarthy, S. F.—This subject is attracting much attention at the present time, being one of great interest to almost every person in our country. The present device relates to certain improvements in the manufacture of gas from crude petroleum and other hydro-carbon oils, by which the inventor claims to be able to produce a gas of superior illuminating qualities and to obtain practically the best results from a given quantity of the crude material. By it nearly all the condensed bituminous vapors, which form tar in the ordinary process, are converted into a gas which produces a light equal to 46 74-100 candles. The advantages, then, are very important in an economical point of view. By increasing the brilliancy of the light and utilizing so much of the material used, not only are the direct results of great value, but also the indirect results. Thus there being but little refuse, the labor of cleaning out the retorts is rendered much less, and there are many other similar advantages which will readily suggest themselves to the mind of the manufacturer of the articles.

* * *

A New Concentrator.—The Central City (Colorado) *Register* gives the following description (which is rather too concise for a good understanding of the machine) of a concentrator recently devised by C. Hawley of that place: The machine is simply a wooden cylinder lined with India-rubber cloth, and rests upon and is revolved by friction rollers. The pulp from the stamps, well diluted, is fed into the cylinder a little above its lowest point. The machine revolves away from the pulp, with the effect that the pyrites settle upon the rubber and sticking to it, are carried away from the sand. When fairly away, doors in its periphery are opened automatically and the heavy particles are washed through by fresh water, and fall on the outside. The whole machine is very simple, and of comparatively slight cost. We were shown concentrations that compare favorably with the best from automatic machines, and show a saving of much finer iron than the common buddle will allow.

* * *

Illustrations on Hand.—Illustrations of the following will appear in the Press in due season: Shaw & Justice's dead-stroke hammer; Henderson's patent direct-action steam pump; patent double-action force pump; combined balance wheel, steam pump and steam engine; new boiler feeder; deep well and mine pump; Solomon Barber's device for steaming rovings; P. C. Ball & Co's rail-car mortising machine [illegible]

Professional Cards.

The California Powder Works
No. 314 CALIFORNIA STREET,

SAN FRANCISCO.

Manufacturers and have constantly on hand

SPORTING,

MINING,

And BLASTING

POWDER,

Of SUPERIOR QUALITY, FRESH FROM THE MILLS. It being constantly received and transported into the interior, is delivered to the consumer within a few days of the time of its manufacture, and is in every way superior to any other Powder in Market.

We have been awarded successively

Three Gold Medals

By the MECHANICS' INSTITUTE and the STATE AGRICULTURAL SOCIETY for the superiority of our products over all others.

We also call attention to our

HERCULES POWDER,

Which combines all the force of other strong explosives now in use, and the lifting force of the BEST BLASTING POWDER, thus making it vastly superior to any other compound now in use.

A circular containing a full description of this Powder can be obtained on application to our Office.

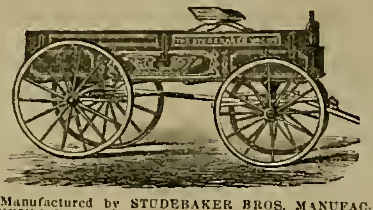
POST OFFICE BOX, 1089.

The Celebrated Studebaker Wagon,



Manufactured by STUDEBAKER BROS. MANUFACTURING CO., South Bend, Indiana. WAGON DEALERS, there are nine reasons why you should buy the above Wagon:

First.—They are made of the best selected INDIANA TIMBER, thoroughly seasoned under cover.

Second.—They are made by experienced mechanics.

Third.—The lightest running and most durable Wagon in the market.

Fourth.—Their Thimble Skeins never break, while all others do.

Fifth.—Most uniform and best proportioned Wagon in the market; any part of one will fit another, while other makes will not

Sixth.—The only Wagon in which the Slope Shoulder Spoke is used; hence they have the best Wheel, which is actually the foundation of the Wagon, and should be carefully examined by persons buying.

Seventh.—They are sold only by responsible parties, and every Wagon is warranted to give entire satisfaction.

Eighth.—Because Teamsters will tell you they are the best Wagons, for all purposes, on the road.

Ninth.—Last, but not least, Studebaker Brothers are practical men, attend to their business personally, and do not entrust it entirely to foremen, as is generally the case in large factories; hence the superiority of their work over all others. Sold by

SAPOINE

FRAGRANT SAPOINE FOR THE TEETH

THE GREAT MEDICAL DISCOVERY!

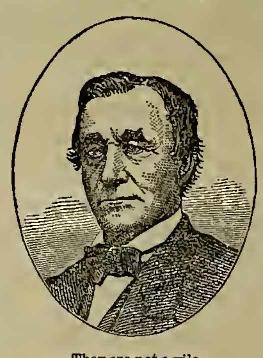
Dr. J. Walker's California

VINEGAR BITTERS.

More than 500,000 Persons

Bear testimony to their wonderful Curative Effects.

WHAT ARE THEY?



FOR FEMALE COMPLAINTS, whether in young or old, married or single, at the dawn of womanhood or the turn of life, these Tonic Bitters display so decided an influence that a marked improvement is soon perceptible in the health of the patient. PIN TAPE, and other WORMS, lurking in the system of so many thousands, are effectually destroyed and removed. ☞ Send for a Circular.

They are not a vile

FANCY DRINK,

Made of Poor Rum, Whiskey, Proof Spirits, and Refuse Liquor, doctored, spiced, and sweetened to please the taste, called "Tonics," "Appetizers," "Restorers," etc., that lead the tippler on to drunkenness and ruin, but are a true Medicine, made from the native roots and herbs of California, free from all alcoholic stimulants. They are the GREAT BLOOD-PURIFIER and LIFE-GIVING PRINCIPLE, a perfect Renovator and Invigorator of the System, carrying off all poisonous matter, and restoring the blood to a healthy condition No person can take these Bitters according to directions and remain long unwell.

They are a gentle Purgative as well as a Tonic, possessing, also, the peculiar merit of acting as a powerful agent in relieving Congestion or Inflammation of the Liver, and all the Visceral Organs. In Bilious, Remittent and Intermittent Fevers, these Bitters have no equal. For full directions, read carefully the circular around each bottle, printed in four languages—English, German, French and Spanish.

One Hundred Dollars will be given for an incurable case, provided the bones are not destroyed by mineral poisons or other means, and the vital organs wasted beyond the point of repair.

For Inflammatory and Chronic Rheumatism, and Gout, Dyspepsia or Indigestion, Bilious, Remittent and Intermittent Fevers, Diseases of the Blood, Liver, Kidneys and Bladder, these Bitters have been most successful. Such Diseases are caused by Vitiated Blood, which is generally produced by derangement of the Digestive Organs.

Cleanse the Vitiated Blood whenever you find its impurities bursting through the skin in Pimples, Eruptions or Sores; cleanse it when you find it obstructed and sluggish in the veins; cleanse it when it is foul, and your feelings will tell you when. Keep the Blood pure and the health of the system will follow.

J. WALKER, Proprietor.

R. H. McDONALD & CO.,
Druggists and General Agents, corner Pine and Sansome streets, San Francisco, Cal., and 32 and 34 Commerce street, New York. 10v20-12t

☞ SOLD BY ALL DRUGGISTS AND DEALERS.

Reading for the Hour.

Singular Climatic Effects.

Fruits grown in the temperate, if transferred to the torrid zone, generally become evergreens, and, for want of their natural winter repose, cannot bring their fruit to perfection. For this reason the apple, peach, plum, grape, etc., cannot be produced in tropical climates. The orange, lemon, banana, etc., are evergreens, and are capable of showing blossoms, and fruit in every stage of growth, at all seasons of the year; they do not require rest—in fact, rest seriously interferes with their existence, and absolute rest, whether accompanied with excessive cold or not, is certain death to them.

The peculiarity mentioned with regard to northern fruits has been overcome, to some extent, with certain kinds, especially with the grape, by laying its roots bare at certain seasons, and exposing them to the strong heat of the sun. This process arrests the circulation of the sap, by which an artificial repose is secured, and two crops of grapes are thus produced each year in a tropical climate.

Little effort has been made to improve indigenous fruits in the torrid zone; but the few experiments that *have* been made, go to prove that much might be accomplished in this direction by intelligent culture. Very little, comparatively, is yet known with regard to the wide adaptability of vegetable products of all kinds, when scientifically treated. California seems to be an appropriate field for such experiments, and we doubt not important advances will be made here within the next twenty years in this interesting department of horticulture.

Chinese Immigration.—A few days ago the heads of the six Chinese companies in this city held a meeting and prepared a circular for distribution throughout China, with a view to stop Chinese immigration to this State. They state that California no longer offers such inducements as formerly, that the placer mines do not repay the labors of those engaged in working them, that there are more here now than can find work to do, and hence many are suffering, and that their people are not respected, but are exposed to violence. Hence they deprecate the policy of sending any more emigrants hither. They add that the Chinese women who have come here have only disgraced their land and they advise all females to remain at home.

A Specimen.—One of those humbugs who roam about the mining districts with loosely-hinged tongues, and by setting up as "scientific" doctors and professors, bring real science into disrepute, is thus feelingly spoken of by the Central City (Colorado) *Register:* In the "note" which follows, all the old residents about Black Hawk will recognize a certain double-thumbed professor of the gold-saving art, one of the first of the line of benefactore in that field. Speaking of the difficulty of saving the gold in the Running lode ore, he said: "The particlee of gold are coated with the gas of lead, and cannot be amalgamated without reduction to a palatable powdor, and not even then without the application of hydraulic and secetic acids."

Arrivals from the East.—We are having a large influx of Eastern visitors, some of whom come to expend their money here and others to take away a part of what we possess. Among the more important of the latter class, now here or expected, may be mentioned Adelaide Phillips, Levy—the cornet player—and Bayard Taylor. P. T. Barnum is here to humbug us, and Major-General-Rear-Admiral Jimmy Fisk is coming to look at our city, and, if satisfied, to buy it.

Sacramento is going to have a street railroad.

Ants at Play.

It is not generally known that some of the smallest insects enjoy themselves in sports and amusements, after their ordinary toils, or, satiating themselves with food, just as regularly as is the case with many human beings. They run races, wrestle with each other, and, out of fun, carry each other on their backs, much in the same manner as boys. These pleasing characteristics are particularly observable among ants, which are remarkable for their sagacity.

Bonnet, a French author, says he observed a small species of ants which, in the intervals of their industry, employed themselves in carrying each other on their backs, the rider holding with his mandibles the neck of his bearer, and embracing it closely with his legs. Gould, another writer on ants, mentions that he has often witnessed these exercises, and says, that in all cases, after being carried a certain length, the ant was let go in a friendly manner, and received no personal injury. This amusement is often repeated, particularly among the hill ants, who are very fond of this sportive exercise. It was among the same species that Huber observed similar proceedings, which he has described with his usual minuteness.

"I approached," he says, "one day to the formicary of wood ants, exposed to the sun, and sheltered from the north. The ants were heaped upon one another in great numbers, and appeared to enjoy the temperature on the surface of the nest. None of them were at work; and the immense multitude of insects presented the appearance of a liquid in a state of ebullition, upon which the eye could scarcely be fixed without difficulty; but when I examined the conduct of each ant, I saw them approach one another, moving their antennæ with astonishing rapidity, while they patted, with a slight movement, the cheeks of other ants. After these preliminary gestures, which resembled caressing, they were observed to raise themselves upright on their hind lege by pairs, struggle together, seize each other by a mandible, foot, or antennæ, and then immediately relax their hold to recommence the attack.

They fastened upon each others shoulders, embraced and overthrew each other, then raised themselves by turns, taking their revenge without producing any serious mischief. They did not spurt out their venom as in their combats, nor retain their opponents with that obstinacy which we observed in their real quarrels. They presently abandoned those which they had first seized and endeavored to catch others. In one place two ants appeared to be gamboling about a stalk of grass; turning alternately to avoid or seize each other, which brought to recollection the sport and pastime of young dogs, when they rise on their hind legs, attempting to bite, overthrow, and seize each other, without once closing their teeth."

Origin of the Guinea.—It is among the things generally known that the guinea obtained its name from the gold from which it was made having been brought from the Guinea coast by the African company of traders. The first notice of this gold was in 1649, during the Commonwealth of England, when on the 14th of April of that year the Parliament referred to the Council of State a paper presented to the House concerning the coinage of gold brought in a ship lately from *Guiny*, for the better advancing of trade. But it was in the reign of Charles II. that the name was given to this coin. It is among things *not* generally known that, when the guinea was originally coined, the intention was to make it current as a 20-shilling piece; but from an error, or rather a series of errors, in calculating the exact proportions of the value of gold and silver, it never circulated for that value. Sir Isaac Newton, in his time, fixed the true value of the guinea, in relation to silver, at 20s. 6d., and by his advice the Crown proclaimed that for the future it should be current at 21s. A curious question arises out of the fact alluded to: How many millions of money has the English public lost by the payment of a guinea when a 20-shilling piece would have sufficed had the costly error never have been fallen into? *Exchange.*

Fenian Raid.—If the telegraphic suspicions are correct, the Fenians are moving in armed bands towarde the frontiers of Canada. The President has issued a proclamation warning citizens of the United States against the commission of overt acts against a friendly power.

When is a Farmer Rich?

Somebody answers the above question as follows: "The best evidence that a farmer is rich will be a pleasant bedroom in his house, containing a spare bed; and there will be such conveniences that the guest will come out ready for the breakfast-table. This room not only represents several thousand dollars, but also good furniture, carpets, and shade in summer. In most families this room is not obtained before the oldest girl has had a beau, or the oldest boy gets the mitten. Moreover, the folks have early cucumbers; and, from July till frost, sweet corn. Every morning the fire is built of dry wood; twice a day, the year round, there is milk to strain; the horses are not heard stamping in the night; the hogs cannot run; nobody eats poor butter, or drinks coffee without cream; pickles are taken out of cider vinegar; if a child has a sore throat, there is no running to a neighbor's for honey; even in September, a few hens are kind enough to lay; if the old man suddenly starts for the country seat, a package of cake and cheese is handed him, and he does not mutter because a clean shirt is not ready; in May, some apples can be found in the bottoms of barrels, and in August, there is lard in crocks and pork in the brine. After breakfast, the father will be likely to read a chapter in the Bible, and then bow before the Creator, confessing His tender mercies.

We care not how many fat cattle a farmer may have, nor how many dairy cows; nor hogs, in a yard four rails high, fed with whey and bran from barrels which steam in the sun; nor how many acres running off toward a river; nor how many thousand dollars are at interest; nor how much folks may stand aside when he goes into the store; if there is not a spare bed in his house, he is a poor man.

The Aldine Press.—The number of more or less praiseworthy art-journals, which are brought to the notice of the public is large. We do not ever remember, however, to have seen any superior production to the *Aldine Press*, published by Sutton, Browne & Co., 23 Liberty street, New York. In fact, we may say that we have never seen any publication in this country which could compare with it. Its illustrations are of the highest order of art, and most beautifully executed, while its literary features are highly commendable and its typography is excellent. We have before us now the March number, which is a credit not only to the publishers, but also to the country where such an artistic production can be sustained. How it can be furnished at its low price ($2 per annum) is something of a financial puzzle.

Mines in New South Wales.—Diamond mining is now an established industry. The principal scene of operations is about 150 miles westward of Sidney, where nearly 2,000 stones have already awarded the efforts of those engaged in the search. The largest gem yet found weighs 5¼ grains, and is almost perfect in form and color. We have also a cinnabar mine, but no person understands anything about it. Iron mines, but no one to work them, and a lead mine, which is more fortunate, inasmuch as it is a genuine success. Our gold yield ie steadily decreasing. The quantity of gold received by escort from the various gold fields during last month exhibits an increase on the receipts during January. The returns for both months show a considerable falling off as compared with the corresponding period in 1869. During the latter period 35,222 ozs. were received, against 24,027 ozs. received during the first two months of 1870.—*Alta.*

Mining in Japan.—The Japanese government has decided to allow foreigners to be employed, under certain regulations, in working the mines of that country. But the restrictions are such that no great influx of "outside barbarians" can be expected just yet.

The Pacific Methodist College, at Vacaville, is closed, for the present at least. Santa Rosa has offered large inducements for its removal thither, and the Trustees are reported as favorably inclined thereto. Vacaville objects.

Reports are again current that the Central Pacific has bought up the California Pacific Railroad.

Our Agents.

Our Friends can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

To Advertisers.

After January 1st, 1870, the latest hour for receiving mining and other advertisements for the M. and S. Press will be during Thursday evening, as our paper will be printed for the interior mails on Friday morning.

A Civil Engineer

Of thirteen years standing and highest Eastern, South American and Pacific coast references, tenders his services at moderate rates. Can present attractive inducements to capitalists. Address W. S. C., Box 1,036, San Francisco. 20v20-1m

☞Maravilla Cocoa.—*For Breakfast.*—The *Globe* says: "Various importers and manufacturers have attempted to attain a reputation for their prepared Cocoas, but we doubt whether any thorough success has been achieved until Messrs. Taylor Brothers discovered the extraordinary qualities of 'Maravilla' Cocoa. Adapting their perfect system of preparation to this finest of all species of the Theobroma they have produced an article which supersedes every other Cocoa in the market. Entire solubility, a delicate aroma, and a rare concentration of the purest elements of nutrition, distinguish the Maravilla Cocoa above all others. For homœpaths and invalids we could not recommend a more agreeable or valuable beverage." Sold in packets only by all Grocers, of whom also may be had Taylor Brothers Original Homœopathic Cocoa and Soluble Chocolate. Steam Mills—Brick Lane, London. 5v20-1y

To Miners, Millmen and Metallurgists. Kustel's new work on the Concentration of all kinds of Ores, and the Chlorination Process, for Gold-bearing Sulphurets, Arseniurets, and Gold and Silver Ores generally, is the best and most complete work issued. It contains 120 diagrams, illustrating machinery, etc., which alone are of the greatest value. Price, $7.50, postage paid. Published by Dewey & Co., publishers of the Scientific Press, San Francisco.

Business Fortunes are often made easily, quickly and legitimately by Patent Rights. We advise both sellers and purchasers to patronize reliable agents only. Weister & Co., patent brokers, No. 314 Bush street, San Francisco, are one of the most honest, reliable firms in the United States. *

We call attention to the new portable gas burner—the only one that can be regulated to any size, flame, and burn without smoke or smell. Equal to any gas at one-fourth the cost. P. J. Philips & Co., 650 Market street, have county rights for sale for this valuable invention; also lamps for sale. No one should be without them who wants a good, cheap and safe light. 21v20-4w

Treatment of Rebellious Silver Ores, by Charles H. Aaron—a pamphlet of eight pages of concise reading, of practical value to parties interested in the subject. Printed and sold by Dewey & Co., at this office, for 25 cents, post paid.

Co-Operative Union Store.—This is becoming one of the most useful Institutions in the city, and the Mechanic and Laboring Man fully appreciate it. They are now enabled to buy their Groceries and Provisions 20 per cent. cheaper than ever before, and the very best articles in the market. The store is located at 115 Sutter street, Lick House Block

To Farmers.—Stevens & Bro's Egg Boxes, holding 30 dozen, supplied free of charge, by John Gray & Co., No. 210 Clay street, San Francisco, to all customers. The eggs are kept cool and free from moisture and mould, are in no danger of being broken, and require no recounting. 20v20-3m

Mason's Bread of Life, for Dyspeptics, Coughs, Colds, Asthma, Catarrh, Hoarseness, Bronchitis and Sore Throat. Price, 25 cents per box. These lozenges are free from all dangerous properties. Compounded and put up by Dr. J. H. Mason, 750 Howard st. 16v20-3m

Photography.—For Cabinet Photographs, or Enameled Cards, of the very best quality, you must go to the NEW YORK GALLERY, Nos. 25 and 27 Third street, San Francisco. Every picture warranted to give satisfaction.
10v18 6m B. F. Howland.

At the age of forty or thereabouts the eyesight requires the aid of magnifying glasses. Muller's Brazilian spectacles are acknowledged to be the best in use. *

New Mining Notices.

Marcelina Mining Company.—Location of

Works: Eureka Mining District, Lander County, Nevada.

Notice is hereby given, that at a meeting of the Board of Trustees of said Company, held on the nineteenth day of May, 1870, an assessment of forty (40) cents per share was levied upon the capital stock of said Company, payable immediately, in United States gold coin, to the Secretary, at 325 Sansome street, San Francisco.

Any stock upon which said assessment shall remain unpaid on Thursday, the twenty-third day of June, 1870, will be advertised on that day as delinquent, and unless payment shall be made before, will be sold on Tuesday, the nineteenth day of July, 1870, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Trustees.

C. C. PALMER, Secretary.

Office, 325 Sansome street, San Francisco. m28

Office of the Placer Gold Mining and Canal

Company.—Location of Works: Township No. Six (6), County of Placer, State of California.

Notice is hereby given, that at a meeting of the Trustees of said Company, held on the ninth day of April, 1870, an assessment (No. 1) of two dollars ($2) per share was levied upon the capital stock of said Company, payable immediately, in United States gold coin, to the Secretary, at the office of the Company, No. 802 Howard street, San Francisco, California.

Any stock upon which said assessment shall remain unpaid on Friday, the twentieth day of May, 1870, shall be deemed delinquent, and will be duly advertised for sale at public auction, and unless payment shall be made before, will be sold on Friday, the tenth day of June, 1870, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Trustees.

C. S. HALEY, Secretary.

Office of Company, 802 Howard street, San Francisco, Cal. Office hours: 6 to 8 P. M. apr16

Postponement.—The day for deeming stock delinquent on the above assessment is hereby postponed until the seventeenth day of June, 1870, and the sale thereof until Friday, the fifteenth day or July, 1870. By order of the Board of Trustees.

m28 C. S. HALEY, Secretary.

Mining Notices--Continued.

Cayuga Chief Mining Company.—Location

of Works: White Pine Mining District, County of White Pine, Nevada.

Notice is hereby given, that at a meeting of the Board of Trustees of said Company, held on the twenty-ninth day of April, 1870, an assessment of fifteen cents per share was levied upon the capital stock of said Company, payable immediately, in United States gold coin, to the Secretary, at the office of the Company, Room 5, No. 302 Montgomery street, San Francisco, California.

Any stock upon which said assessment shall remain unpaid on the thirty-first day of May, 1870, shall be deemed delinquent, and will be duly advertised for sale at public auction, and unless payment shall be made before, will be sold on Tuesday, the twenty-first day of June, 1870, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Trustees.

WM. H. WATSON, Secretary.

Office, Room No. 5 No. 302 Montgomery street, San Francisco, Cal. my7

Land Purchasers' Association.—Notice.

At a meeting of the Board of Trustees of the Land Purchasers' Association, held May 3d, 1870, the following resolution was adopted by unanimous vote:

Resolved, That an assessment of ten dollars per share, gold coin, be, and the same is hereby levied, upon each and every share of the capital stock of the Land Purchasers' Association now held by subscribers thereto; being for the monthly installment falling due and payable May 1st, 1870. Said assessment is payable on or before the thirtieth day of May, A. D. 1870, to James F. Crosett, Secretary, at the office of the Association, No. 304 Montgomery street, San Francisco.

Any stock upon which said assessment shall remain unpaid on the thirtieth day of May, A. D. 1870, shall be deemed delinquent, and will be advertised for sale at public auction, and unless payment shall be made before, will be sold at the office of the Secretary, on the twenty-eighth day of June, A. D. 1870, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

J. F. CROSETT, Secretary.

Office, 304 Montgomery street, San Francisco. m7-4w

Nevada Land and Mining Company.—Location of Works:

Steptoe, Johnson & Latham, Antelope and Clifton Districts, Elko County, State of Nevada.

Notice is hereby given, that at a meeting of the Board of Trustees of said Company, held on the third day of May, 1870, an assessment of three (3) cents per share was levied upon the capital stock of said Company, payable immediately, in United States gold coin, to the Secretary, at his office, Room 5, No. 302 Montgomery street, San Francisco, California.

Any stock upon which said assessment shall remain unpaid on Tuesday, the seventh day of June, 1870, shall be deemed delinquent, and will be duly advertised for sale at public auction, and unless payment shall be made before, will be sold on Tuesday, the twenty-eighth day of June, 1870, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Trustees.

WM. H. WATSON, Secretary.

Office, Room 5, No. 302 Montgomery street, San Francisco, California. my7

Pinto Mining Company.—Location of

Works: "Silverado," Pinto District, White Pine County, Nevada.

Notice is hereby given, that at a meeting of the Board of Trustees of said Company, held on the second day of May, 1870, an assessment of ten cents per share was levied upon the capital stock of said Company, payable immediately, in United States gold and silver coin, to the Secretary, No. 426 Montgomery street, San Francisco, California.

Any stock upon which said assessment shall remain unpaid on the second (2d) day of June, 1870, shall be deemed delinquent, and will be duly advertised for sale at public auction, and unless payment shall be made before, will be sold on Monday, the twentieth (20th) day of June, 1870, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Trustees.

D. B. ARROWSMITH, Secretary.

Office, 426 Montgomery street. 1Lv20

A Valuable Book for Inventors and Artisans.—Dewey & Co., publishers of the Scientific Press and Patent Agents, have just issued a neat little volume of over five hundred well executed cuts of the principal mechanical movements known. These useful representations of the various appliances of power are printed side by side with explanatory notes, which makes the subject clear to every reader. Such a book should be in the hands of every mechanic, and form part of every public school library. It is a handy book, and cheap enough for every farm, shop and factory. Sent to any address from the Scientific Press office, postpaid, for $1.—*New Age.*

Silver Vault Tunnel and Mining Company.

Location of Works: White Pine Mining District, White Pine County, State of Nevada.

Notice is hereby given, that at a meeting of the Board of Trustees of said Company, held on the third (3d) day of May, A. D. 1870, an assessment of five (5) cents per share was levied upon the capital stock of said Company, payable immediately, in United States gold coin, to the Secretary, at the office of the Company, Room 23 Hayward's Building, No. 419 California street, San Francisco, California.

Any stock upon which said assessment shall remain unpaid on Thursday, the ninth day of June, A. D. 1870, shall be deemed delinquent, and will be duly advertised for sale at public auction, and unless payment shall be made before, will be sold on Wednesday, the twenty-ninth day of June, 1870, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Trustees.

JOSEPH L KING, Secretary.

Office, Room No. 23 Hayward's Building, No. 419 California street, San Francisco, California. my7

The large majority of United States and Foreign Patents granted to inventors on the Pacific coast during the past few years, have been obtained through the agency of Dewey & Co., publishers of the Scientific Press. Established in the year 1860, we have an extensive patent library, with full record of cases on this coast, and can give the best and most reliable advice as to the patentability of new inventions.

The Latest, Cheapest, and Most Durable.

CRANDALL'S

PATENT SPRING BED.

This invaluable Spiral Spring Bed combines all the good without any of the bad features of the common spring mattrass. It consists of a framework of springs resting on a bed of stronger springs, thus giving it nearly double the elasticity of any other bed. The springs are self-supporting, each pair being independent of the others, and consequently the tendency to sag or incline toward the middle is avoided. Unlike other spring beds, they require no upholstering, and, of course, afford no harbor for fleas or dust. The medical faculty have pronounced it the best Bed in use. It commends itself to those who have examined and used it. They invariably pronounce Crandall's Patent the best Spring Bed ever offered to the public.

These Beds are on exhibition and for sale at the Cabinet Warerooms of

JOHNSON & BEST,

No. 413 PINE STREET, RUSS BLOCK,

Between Montgomery and Kearny. Also at

639 Market Street, near New Montgomery.

Beds guaranteed to give satisfaction

Or the money will be refunded.

Refer, by permission, to the following, among the many using our Beds, who are willing to testify to their superiority:

San Francisco and Vicinity—J. B. Pierce, Esq., residence Sixteenth and Capp streets, office 315 California street; J. H. Rogers, Esq., residence Oakland Point, office 16, 17 and 18 California Market; W. Zelbeer, Esq., residence 613 Geary street; James Doxter, Esq., office 430 Sansome street; John A. Roth, Esq., residence 106 Silver street. James Connor, Esq., Alameda.

N. B.—Responsible persons can have one on trial.

Sheffield Scientific School

Of Yale College, New Haven, Conn.

This department of Yale College, instituted in 1840, and endowed with the National Land Grant in 1866, furnishes advanced instruction in the various branches of Mathematical, Physical, and Natural Science.

The School is under the direction of the President of the College, a Board of thirteen Professors in differe specialties, and six assistant instructors.

Regular courses of study, leading to the degree of Bachelor of Philosophy, conferred by Yale College, are arranged as follows: 1—Chemistry and Mineralogy. 2—Civil Engineering. 3—Mechanical Engineering. 4—Mining Engineering and Metallurgy. 5—Agriculture. 6—Natural History and Geology, and 7—Select Course.

Advanced students are also admitted to optional courses, and if already College graduates, are received as candidates for the degree of Doctor of Philosophy.

Tuition, $125 per year of forty weeks.

The Libraries, Museums, Laboratories and Apparatus accessible to students, are varied and extensive.

For copies of the Annual Circular and Report, letters may be addressed to the "Secretary of the Sheffield Scientific School," New Haven, Conn. v16-1y16p

CANVASSERS WANTED for a New Book: THE CHEMICAL FORCES—HEAT, LIGHT, ELECTRICITY; Their Application to Important Modern Inventions and Scientific Discovery, by Thomas Ruggles Pynchon, Professor of Chemistry and the Natural Sciences, Beautifully Illustrated by 259 Engravings and by many entertaining experiments. The work is elegantly printed. All experienced agents should send for descriptive circular and terms. F. DEWING & CO., 612 California street, San Francisco. 19v20-5w

Scientific Press.—The Mining and Scientific Press, which has been a faithful exponent of the scientific, mechanical and industrial interests of our western coast, entered upon its twentieth volume on the first of January, and at the same time adopted the shorter and equally comprehensive title of Scientific Press. This journal has, for some time past, maintained a department specially devoted to agricultural matters, and has filled it with useful and interesting information.—*Contra Costa Gazette, Jan.*, 1870.

MINING SCHOOL.

Mosheimer's Practical Mining School

Will be reopened by the FIRST OF JUNE, and practical instruction given in all branches of Assaying, Crushing, Amalgamating, Concentrating, Smelting and Refining Ores; also Erecting Furnaces and Reduction Works of every kind. To give all miners a chance to learn Assaying of Ores (what everyone ought to) I have reduced my former charge for

Assaying Ores	$ 50.00
To work Gold and Silver Ores	100.00
Smelting and Refining, including Assaying	150.00

Many gentlemen who have been taught in my establishment will bear testimony that in a few days they learned more than they expected to learn in a month. Before going into mining, every man ought to know how to test ores, and then he will go to work with prudence and never fail to be successful. Apply to

J. MOSHEIMER,

Office, 328 Montgomery street; Works, 2,005 Powell street, San Francisco. 22v23-3m

CRANDALL'S PATENT SPRING BED.

COOLEY & GREEN, Proprietors.

Manufactory, corner Front and M streets, Sacramento. These Spring Beds, wherever known, are universally acknowledged to be superior to any other in use. They are light, durable and elastic, and present no harborage for bugs or any other kind of vermin, thus being free from the objections so often urged against the ordinary spring beds. Orders receivd at our manufactory, or at our agencies, as follows.

Between Third and Fourth, San Francisco. Orders from the country promptly attended to. All kinds of Stair Material furnished to order. Wood and Ivory Turners. Billiard Balls and Ten Pins. Fancy Newels and Balusters.

Greatest Discovery Ever Made.

MR. J. W. MAC, while a resident in New Zealand, was so afflicted with the RHEUMATISM, that for years he was completely crippled and unable to attend to business. The symptoms were of the worst type—knees painful and swollen, with sinews contracted; shoulder, arm and hand rendered useless, and accompanied with continued excruciating pain. While in this state of suffering, he got acquainted with a native of the country, who applied to the parts affected a composition spread on coarse canvas, the properties of which were so wonderful that in a short time all the pain left him, the swelling disappeared, his sinews relieved, and he was able to resume his usual avocations. So effectual has been the remedy, that to this day he has enjoyed perfect health, without the slightest return of his former complaint. Knowing the great blessing such a remedy would be to those afflicted with this painful disease, he with great difficulty and expense obtained the secret of preparing the Plaster; and during the many years MR. MAC has applied these Plasters in New Zealand, Tasmania, New South Wales, and this city, their effect has been marvelous, giving to the most painful and long-standing cases sure and certain relief. The most incredulous will be convinced by referring to these persons: B. W. Owens, 405 Front street; F. B. Alderson, Traveling Agent for Dewey & Co., 414 Clay street; James Flynn, 519 Mission street: Michael Gorman, No. 6 Front street; Mrs. W. S Wright—late of Gilmore House—518 Folsom street, now agent at Virginia City; E. Shenley, corner Montgomery and Filbert streets; W. M. McLeod, Depository merican Tract Society, 557 Market street, and a host of others, who all bear testimony to the unparalleled healing powers of J. W. MAC'S (rightly termed Magic) Plasters, for the cure of Rheumatism, Gout, Weak Loins, Tender Feet and Neuralgia. J. W. MAC may be consulted at his office, rooms Nos. 34, 35 and 36, 128 Kearny street, San Francisco, between the hours of 9 to 12 A. M., 2 to 4 P. M. and 7 to 9 P. M.

PARIS

Scouring and Blanket Cleaning

ESTABLISHMENT.

Blankets are cleaned in such a manner as to give them their original elasticity and gloss. Flannels of all kinds are cleansed and scoured *without fulling.* Ladies' Dresses and Wearing Apparel of all kinds are scoured and cleansed after the latest Paris style, for which Mr. Weyer's father was awarded a Medal at the Paris Fair. Silk Dresses are prepared so as to have their original gloss and appearance. Furs neatly cleaned. Curtains are washed and done up in a superior manner. Gent's Clothing of every description scoured and cleaned so as to look as well as new. Samples can be obtained at the Powell street establishment and in the branch offices, showing that my work is done in a superior and skillful manner that will suit the most fastidious. Orders called for and delivered without extra charge.

Parties in the country can have their work done well and promptly by sending their goods with orders by express.

A. WEYER, proprietor, No. 1719 Powell street; branch offices, 122 Fourth street, and 862 Folsom street. ORDER BOXES, 740 Washington street, corner Sutter and Powell, corner Fifth and Howard, corner Powell and Bush. 10v20-3m

USE

DR. S. GIRARD SMITH'S

ARAMIRACULAS

— FOR —

RHEUMATISM, GOUT AND NEURALGIA

CURES GUARANTEED.

Has cured Thousands. Has never been known One bottle will relieve you.

OFFICE, No. 121 POST STREET

Agents Wanted in every City and Town.—Terms Liberal.

Dr. S. Girard Smith, 621 *Kearny street.*—Dear Sir It would be hard for me to say how much I thank you for the benefit your ARAMIRACULAS has conferred on me in curing my RHEUMATISM. I was confined to my bed when I first commenced to take your medicine, and after using ONE BOTTLE I am now able to work as well as before. If you know anything about having that afflictive complaint, you must know how good it is to be cured. I will state to those who may not believe in your medicine, that they can be convinced by referring them to me. Very respectfully, yours,

ENON HARRIS,
Everard's Auction Rooms, 527 Kearny street.

Statement of an old and well-known Physician who has practiced extensively in Europe and America.

We must admit that the many systems of medicine by which we have attempted to heal the human body, and rid it of disease, from the science of ALLOPATHY down to HYDROPATHY, how little they have succeeded, time has abundantly shown by their number of failures. In the cure of RHEUMATISM, GOUT and NEURALGIA, Dr. S. Girard Smith has laid aside the old way and adopted a system, so simple, that I must admit, is so natural and direct, that it recommends itself to all who are suffering with the above diseases. And it challenges and defies all the old methods of treatment. Although I have been educated through a regular course, and graduated in Europe, I must acknowledge the right, and also give due credit for personal benefit received by the new system as practiced by DR. S. GIRARD SMITH, which induces me to bear this testimony to its merits, for the benefit of suffering humanity.

A. M. HOFFMAN, M. D.,
11v20-3m New Orleans.

Ayer's Sarsaparilla,

FOR PURIFYING THE BLOOD.

The reputation this excellent medicine enjoys, is derived from its cures, many of which are truly marvellous. Inveterate cases of Scrofulous disease, where the system seemed saturated with corruption, have been purified and cured by it. Scrofulous affections and disorders, which were aggravated by the scrofulous contamination until they were painfully afflicting, have been radically cured in such great numbers in almost every section of the country, that the public scarcely need to be informed of its virtues or uses.

Scrofulous poison is one of the most destructive enemies of our race. Often, this unseen and unfelt tenant of the organism undermines the constitution, and invites the attack of enfeebling or fatal diseases, without exciting a suspicion of its presence. Again, it seems to breed infection throughout the body, and then, on some favorable occasion, rapidly develop into one or other of its hideous forms, either on the surface or among the vitals. In the latter, tubercles may be suddenly deposited in the lungs or heart, or tumors formed in the liver, or it shows its presence by eruptions on the skin, or foul ulcerations on some part of the body. Hence the occasional use of a bottle of this *Sarsaparilla* is advisable, even when no active symptoms of disease appear. Persons afflicted with the following complaints generally find immediate relief, and, at length, cure, by the use of this *SARSAPARILLA: St. Anthony's Fire, Rose or Erysipelas, Tetter, Salt Rheum, Scald Head, Ringworm, Sore Eyes, Sore Ears,* and other eruptions or visible forms of *Scrofulous* disease. Also in the more concealed forms, as *Dyspepsia, Dropsy, Heart Disease, Fits, Epilepsy, Neuralgia,* and the various *Ulcerous* affections of the muscular and nervous systems.

Syphilis or *Venereal* and *Mercurial Diseases* are cured by it, though a long time is required for subduing these obstinate maladies by any medicine. But long continued use of this medicine will cure the complaint. *Leucorrhœa* or *Whites, Uterine Ulcerations,* and *Female Diseases,* are commonly soon relieved and ultimately cured by its purifying and invigorating effect. Minute Directions for each case are found in our Almanac, supplied gratis. *Rheumatism* and *Gout,* when caused by accumulations of extraneous matters in the blood, yield quickly to it, as also *Liver Complaints, Torpidity, Congestion* or *Inflammation* of the *Liver,* and *Jaundice,* when arising, as they often do, from the rankling poisons in the blood. This *SARSAPARILLA* is a great restorer for the strength and vigor of the system. Those who are *Languid* and *Listless, Despondent, Sleepless,* and troubled with *Nervous Apprehensions* or *Fears,* or any of the affections symptomatic of *Weakness,* will find immediate relief and convincing evidence of its restorative power upon trial.

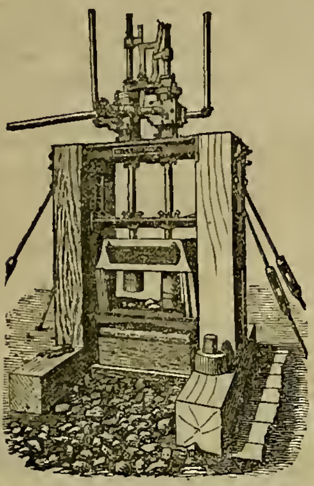
THE WILSON

Patent Steam Stamp Mill.



This extraordinary Mill, now so justly popular in the East, is now offered to the miners of the Pacific Coast. Having been in operation now for about eighteen months, the Company feel confident that the

WILSON STEAM STAMP MILL,

For Durability, Efficisncy,

AND ECONOMY OF WORKING,

HAS NO EQUAL.

The Wilson Steam Stamp Mill is the only Steam Mill that has had the severe ordeal of practical working, and proved itself eminently successful. It is now in operation in several of the Eastern States and Territories, and gaining an envious popularity. The whole machine is so simple as to be readily understood by the most ordinary minds. In fact, its simplicity is its durability. The expense of crushing rock or cement with this Mill is less than one-half the expense of any other Stamp Mill, and less than one-half the cost. For further particulars inquire of

A. BICKNELE, Agent,
Nevada City, California,

Or of THE WILSON STEAM STAMP MILL CO., 326 Walnut street, Philadelphia, Pa.

Notice.—All persons are hereby warned not to manufacture or use any Steam Stamp Mills that are an infringement on the Wilson Patents, as they will be prosecuted to the utmost rigor of the law.

F. R. WILSON,
20v19-tf Supt. W. P. S. S. M. Co., Philadelphia.

VARNEY'S PATENT AMALGAMATOR

These Machines Stand Unrivaled.

For rapidly pulverizing and amalgamating ores, they have no equal. No effort has been, or will be, spared to have them constructed in the most perfect manner, and of the great number now in operation, not one has ever required repairs. The constant and increasing demand for them is sufficient evidence of their merits.

They are constructed so as to apply steam directly into the pulp, or with steam bottoms, as desired.

This Amalgamator Operates as Follows:

The pan being filled, the motion of the muller forces the pulp to the center, where it is drawn down through the aperture and between the grinding surfaces. Thence it is thrown to the periphery into the quicksilver. The curved plates again draw it to the center, where it passes down, and to the circumference as before. Thus it is constantly passing in a regular flow between the grinding surfaces and into the quicksilver, until the ore is reduced to an impalpable powder, and the metal amalgamated.

Setlers made on the same principle excel all others.—They bring the pulp so constantly and perfectly in contact with quicksilvor, that the particles are rapidly and completely absorbed.

Mill men are invited to examine these pans and setlers for themselves, at the office, **229** Fremont street, San Francisco.
1v1

TO MILLMEN.

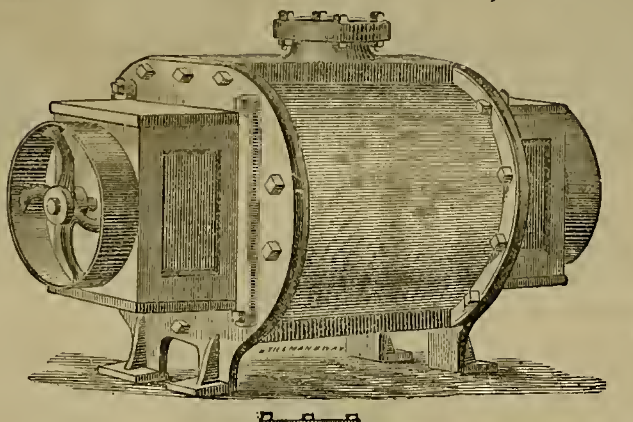
FOR SALE CHEAP.—A 10-stamp mill complete; engine about 35 horse-power; cylinder 12-inch bore and 30-inch stroke; boiler 16 feet long and 48 inch diameter; weight of stamps complete, 650 pounds. The whole is as good as new; has only been running four months. Will sell either engine or battery separate, and deliver it on the railroad at Auburn if required. For particulars apply to W NAGEL, 702 Bush street, San Francisco, or to MOUNTAIN CO., Forest Hill, Placer county. 16v20-3m

ROOT'S PATENT FORCE BLAST ROTARY BLOWER.

MANUFACTURED BY KEEP & BARGION,

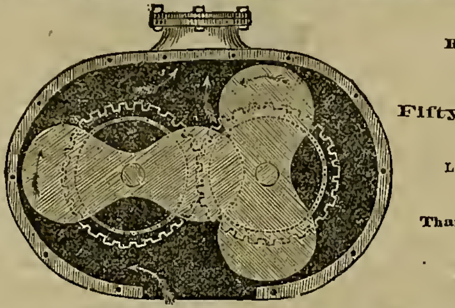
At the Globe Iron Works, Stockton, California.

Awarded the First Premium at the Paris Exposition.



Patented Nov. 1st, 1864; July 24 1866; and Oct. 9, 1866.

ADAPTED FOR **Smelting, Foundry, Mining and Steamships.**



REQUIRES Fifty Per Cent. LESS POWER **Than any Blower** Now in use.

One of these Blowers may be seen on exhibition at W. T. Garratt's Brass Foundry, corner of Mission and Fremont streets. They are also in use at the Almaden Quicksilver Mine; Gridley's Foundry, Gold Hill, Nevada; Ætna Iron Works, San Francisco, and many other places.

Caution.—Purchasers will find it to their advantage to apply direct to the Stockton Agency, as certain parties, not authorized to manufacture the Blower, have put in the market machines of inferior construction, which do not answer all the requirements of the genuine article.

Quartz, Saw and Grist Mill Irons, Steam Engines, Horse Powers, High and Low Pressure Steam Engines, Steamboats and Propellers, made at short notice.

For circulars and further information, address

KEEP & BARGION,

Crucibles.

The Patent Plumbago Crucible Co.

Manufacturers of sll kinds of

Melting Pots, Portable Furnaces,
CRUCIBLES, and other fire-standing Goods,
Battersea Works, London.

THE MORGAN PATENT CRUCIBLES hsve nniform quality, never crsck, withstand the greatest heat without danger; heats more rapidly than any other; change of temperature has no effect on them; stand on the average forty to fifty ponrlugs.

CERTIFICATES:

United States Branch Mint, San Francisco, Cal., March 12, 1869—Messrs. A. S. Hallidie & Co., Agents Morgan Crucible:—I have carefully tested the Morgan Patent Plumbago Crucibles purchased from you for the U. S. B. Mint, and cheerfully certify to their superiority and economy over all other Crucibles used by and under me. They are fully what you represent them, and I shall continue to use them in prefereuce to any other. J. M. ECKFELDT,
Melter and Refiner, U. S. B. Mint.

Eagle Brass Foundry, 206 Fremont street, San Francisco 12th Msrch, 1869—Messrs. A. S. Hsllidie & Co., 519 Front street—Gentlemen:—We have used and tested the Morgan Patent Plumbago Crucible, for which you are agents, and pronounce them superior to and cheaper thsn sny Crucible used by us heretofore. GREENBERG & MOORE.

Messrs. A. S. Hsllidie & Co.:—We have thoroughly and severely tested in every way the Morgan Patent Plumbago Crucible obtained by us from you, and find them superior to any we have yet tried, although we have used every pot obtainable in this market, we have none equal to the above, and concede your claims for them. We think they will average 45 pourings of brass.
GALLAGHER, WEED & CO,,
Csllfornia Brass Works, 125 Front street, San Francisco.

Assay Office of H. Harris, Silver City, Nevada, April 24, 1869—Messrs. A. S. Hallidie & Co.—Gents.:—I received from you three Crucibles of the Morgan make, which I have used since their arrival, and tested by constant use. Since 1847, when in the New Orleans Mint, I have always preferred the Crucible of Dixon's make over Adus, Gautier, and Taunton, Mass. Yours I find to be not alone of more finished make, but to stand double or treble the work of Dixon's Crucibles. The No. 12—the smallest sent—has stood so far 32 meltings, and is as good and sound ss when received. Your Crucibles do not scale off like others; and as they are forty per cent. cheaper, I do not see why they should not be preferred by all assayers on account of durability and cheapness. Yours respectfully, H. HARRIS.

Patents on the Pacific Coast.—To those of our friends who desire to keep posted upon inventions upon the Pacific coast we say, subscribe for the Scientific Press, published by Dewey & Co., San Francisco, Cal., at $4 per year. The opening of the railway across the continent has given to all patents a much higher value in that portion of our country known as the Pacific slope, and all interested will find the paper above alluded to a valuable reference.—*Mechanic and Inventor Detroit, Michigan.*

WIESTER & CO.,

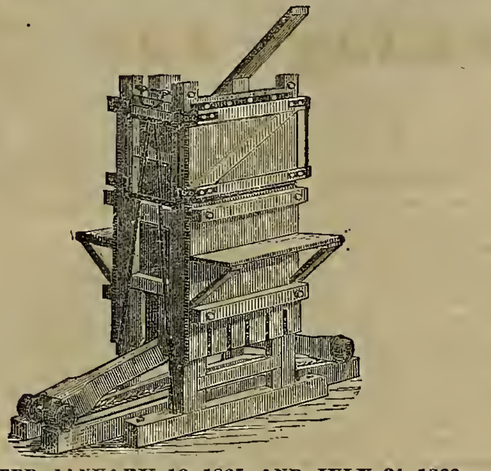
PATENT BROKERS,

No. 314 Bush Street, San Francisco.

PATENTS BOUGHT AND SOLD ON COMMISSION.

For the benefit of those who live at a distance from the city, we give below a brief description of a few of the vsluable Patents which we have in our office. It may be well to stste here that no Patent is received by us for negotiation until it is first endorsed by reliable experts, to whom esch is subjected for acceptance or rejection. We treat all patents alike, recommending only where true merit is found in the invention.

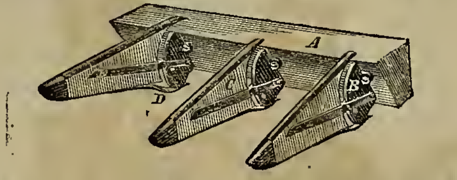
EAGLE HAY PRESS.



PATENTED JANUARY 10, 1865, AND JULY 24, 1866.

Here is an invention that we take pleasure in recommending. There is probably no farming implement more perfect in its line than this Press. It has advantages over any and all other Presses now in use. It costs only $300 snd weighs only 1,500 pounds, which is $100 lower in price and 1,500 pounds less in weight than any other good Press on the Pacific coast Three men and a pair of horses with this Press can bale from ten to fifteen tons per day, each bale weighing from 250 to 350 pounds. The power is applied by means of two levers acting on the principle of the toggle-joint, and the pressure acquired ss they approach a vertical position can scarcely be estimated. On sccount of the great power obtained in this Press, it is well adapted to baleing hides, rags, wool, cotton, etc. They can be built at any blacksmith and wsgon shop. They cost to manufacture $150 less than any other firs-class Press in the United States. A large number have already been sold, and all are giving good satisfaction. The Right to California, Oregon and Nevada will be sold in States or counties. We keep on hand woll built sample Presses to furnish to parties huying territory. Any informstion in regard to tho Press or territory can be obtained by addressing WIESTER & CO., 314 Bush street, Ssn Francisco.

BONNEY'S IMPROVED GRAIN LIFTERS.



Patented July 21, 1868, and September 28, 1869.

Mr. O. BONNEY, Jr., of San Francisco, has invented and patented a simple and practical device for raising fallen down grain, that it may be secured by the knives of the header. Practical farmers and those whose interests are closely allied with them, can testify to the great amount of grain that cannot be gsthered by the heading machines in use, and which is annually lost to themselves and the country.

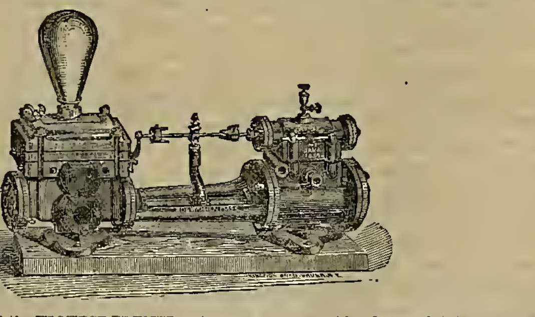
It has been estimated that with the ordinary Harvester one bushel to the acre, on an average, is annually wasted in the State of California. Taking this estimate, which we think is very low, by the use of BONNEY'S IMPROVED GRAIN LIFTERS there would be annually saved to the people of this State more than 700,000 bushels of whest, 400,000 bushels of barley, snd 40,000 bushels of oats. In the above cut three Lifters are represented. A is the header beam, b sn iron shank firmly bolted to tho beam, to which the finger or lifter, c, is fastened by means of a joint bolt through the iron and the back part of the shank, b. The lifter has an iron point, and is bound with iron, which makes it very durable. They sre smooth, affording no chance for grain to hang and burden a team. D is a strip of spring steel, and draws the point of tho finger downward. By means of a stop-bolt through the front part of the shank, b, any angle can be given to the Lifter. They can be varied from one inch to two feet from the ground. By elevating the Lifters, they become a complete substitute for what are termed "trinklers," allowing the knives to run close to the ground. The hinge motion of the Lifters prevents them from injuring the header-beam in passing over rough ground. The entire weight of a full set of eight Lifters is forty-eight pounds. One minute is sufficient time to put on or take off each finger.

We claim that this auxiliary for harvesting is much superior to anything else of the kind ever invented, and are prepared to prove the same in the field. A single Lifter will be sent (C. O. D.) at the retail price—five dollars—to any person who may wish to exsmine them either with a view to buy territory or to purchase Lifters for his own use. If the Lifter is not satisfactory, it can be returned, and we will refund the money, less express charge on the Lifter. We will furnish Lifters at what they cost to manufacture to any person who buys a County or State Right. They can be made at any blacksmith shop, and allow a handsome profit. For Lifters or Rights address WIESTER & CO., 314 Bush Street, San Francisco.

☞ We have for sale the Right of A NOVEL AND VALUABLE LITTLE INVENTION for the city of San Frsncisco. One machine will go with the right. The machine can be attended by a man or small boy, and will yield to the owner a net profit of from two to four dollars per day. The present owner has built up a paying business, but is induced, at the request of friends, to relinquish it snd go East. The Right and tho Machine will be sold for the small sum of $175.

WIESTER & CO.,
314 Bush Street, San Francisco.

KNOWLES' PATENT STEAM PUMP.



This Pump has received the HIGHEST PREMIUM at every Fair where it has been exhibited. It is of superior make and finish; has sll ground joints; no packing required. It is positive in its action. It is impossible to stop it on centers. It will always start without using a starting bar. We have two hundred different styles and sizes adapted for Factories, Steamships, Sugar Refineries, Breweries, Distilleries, Gas Works, Oil Works, Soap Works, Paper Mills, Tanneries, Bleacheries, Laundries, Railroad Purposes, Quarries, Petroleum Minea, Drainage, etc. Large Pumps for Water Works. Fire and Wrecking Pumps. ☞ Pumps guaranteed for every situation.

E. T. STEEN & V. CUSHING,
Sole Agenta for the Pacific Coast,
No. 9 FIRST STREET. SAN FRANCISCO.

NEW AND SECOND-HAND ENGINS, BOILERS, and MACHINERY OF ALL KINDS, constantly on hand.

W. T. GARRATT & CO.

CITY

Brass and Bell Founder,

Corner Mission and Fremont Streets,
MANUFACTURERS OF
Brass, Zinc and Anti-Friction or Babbet Metal
CASTINGS,
Church and Steamboat Bells,
TAVERN AND HAND BELLS, GONGS,
FIRE ENGINES, FORCE AND LIFT PUMPS.

Steam, Liquor, Soda, Oil, Water and Flange Cocks, and Valves of all descriptions, mado and repaired. Hose and all other Joints, Spelter, Solder and Copper Rivets, etc. Gauge Cocks, Cylinder Cocks, Oil Globes, Steam Whistles. HYDRAULIC PIPES AND NOZZLES for mining purposes. Iron Steam Pipe furnished with Fittings, etc. Coupling Joints of all sizes. Particular attention paid to Distillery Work. Manufacturer of "Garratt's Patent Improved Journal Metal."

Progress of the Silk Business in California.

The silk business of this State is steadily progressing, and is already giving employment to a goodly number of persons, and employing no inconsiderable amount of capital. The California Silk Manufacturing Company has been fully organized. A factory building, 50x125 feet, two stories high, is to be erected on a lot near the new woolen mills, on the flat just beyond Islais creek. The heavy machinery for the factory will be built in this city—the lighter and more complicated portions being imported from New York. George T. Crowther, an experienced silk manufacturer, has been secured as the manager. Mr. C. is also a large stockholder in the concern.

Many are of the opinion that within a few years the silk business of this State will be more important than either our gold, wheat or wine. However that may be, there seems to be a steady advance in the business, such as is very encouraging for important results in the early future.

The first silk-worms in this State were hatched in 1860, and were only 500 in number. Since that time the increase, from year to year, has been reported about as follows: 1,000, 2,000, 4,000, 30,000, 100,000, 300,000, 500,000, 2,700,000, 3,500,000; the number for the present year is estimated as high as 25,000,000. Much experience has been gained, and many heretofore causes of loss will be successfully guarded against in the future.

The market for eggs continues undiminished; in fact, there appears to be no limited to such demand, although their offering in large numbers may have a tendency to reduce the price somewhat.

The silk manufacturers in New Jersey are looking forward with much confidence to the time when their looms will be largely supplied with raw silk from California. Some of the leading manufactures have sent agents to this State to examine carefully into the condition and prospects of the business here. Mr. William Angus, who recently visited California, with this object in view, has made a most favorable report at the East. He considers the specimens of raw silk produced here equal to the best of India or Japan—the fiber being very strong, fine, free from impurities, and remarkably smooth and glossy. Mr. Ryle, of Patterson, New Jersey, has also been here on a similar errand, and made equally flattering reports.

Mr. R. says all that is wanting to make the culture of silk successful in California is machinery for reeling the cocoons in the districts where they are produced. Without machinery for reeling, it will be difficult to do anything else with the cocoons than to employ them for the production of eggs. We think Mr. Ryle is mistaken in supposing that it will be necessary to procure such machinery at the East. There is no doubt but that it could be made here cheaper than it can be imported, and most effective and perfect in construction.

The New York *Tribune* says that "negotiations are being made by Mr. R. with persons in California who desire to embark in the enterprise for setting up the necessary machinery for reeling in California, and purchasing the entire product of cocoons. A new machine has been completed and is now at the Ryle silk mill in Patterson, for reeling cheaply and speedily, and it is probable that it will be tried on an extensive scale in California. The subject is interesting the silk manufacturers of Patterson, who see in the new enterprise advantages to the nation, and particularly to its great silk manufacturing center, that cannot easily be estimated."

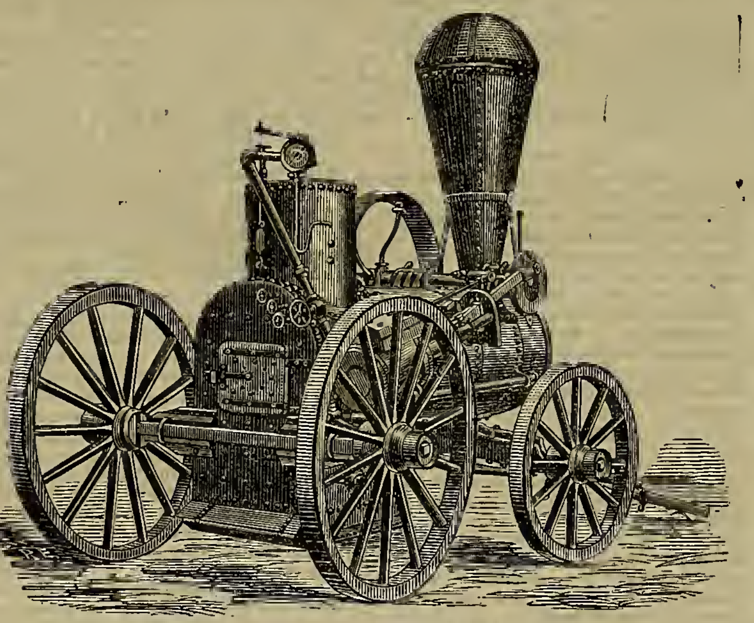
An opinion seems to have obtained at Macclesfield, the chief seat of silk manufacture in England, that it would be preferable for manufacturers there to import the cocoons rather than the reeled silk. They think they can better protect themselves from certain serious frauds by doing their own reeling. If this idea should be found practicable and put in progress by the Macclesfield manufacturers, on terms which would give a fair margin for profit to our cocoon producers, it would no doubt give a great impetus to the business here, as hundreds would raise cocoons, provided a ready and profitable market could be obtained for them, who would not go into the more difficult or delicate processes of producing the eggs or raw silk.

◆

ODD FELLOWSHIP IN GERMANY.—Mr. F. B. Austin, the able editor of the *New Age*, and one of the oldest of the California Odd Fellows, is to go to Europe with Dr. J. F. Morse, to organize and establish the fraternity in Germany.

Steam Engines for Field-Threshing.

Ten years ago in the town of Napa there was constructed the first of these engines of which the cut is a representation. It was the pioneer of the State and its introduction was an important fact in the history of farming upon the Pacific coast. The first having proved a success, the proprietor was soon enabled to place a second in the field, which fully sustained the reputation earned by its predecessor and opened the way through which has flowed a gradually increasing demand for the California Steam Thresher until, in the place of confining himself to the manufacture of a limited number yearly, the proprietor has made their construction a specialty in his business, and is now prepared to fill orders to any extent. Having had ten years' practical experience in the harvest field, using many different kinds of engines, he feels confident, as he says, of having produced one better adapted to the wants of the farming community than any other in the market, and offers it to the public as a complete machine with all the modern improvements, at a very reasonable price. Some of the advantages claimed by Enright's Cal. Steam Thresher Engine are, its lightness, compactness and great durability; its low price; its furnishing an abundance of power, while consuming but little fuel; and its requiring no protection from the weather. Its best recommendation, however, is the growing favor with which it is received by the public. Many testimonials have been received from parties owning and running these engines, of which we give the following: Messrs. Ricker and Elkins, writing from Half Moon Bay, under date of April 21st, 1870, say: "We are using two of your thresher engines, one of which is the first you made in this State. It is the pioneer of the coast, and we have used it for ten years with perfect satisfaction. The second one was four years old when we purchased it three years ago. It has also given good satisfaction. They are both made of the best material, as is conclusively proved from the fact that we have been to but trifling expense for repairs on either of them, and as old as the *pioneer* is, we would not exchange it for any Eastern machine that we have ever seen. We take great pleasure in recommending your thresher engines to the public, and any one desiring information as to particulars is at liberty to apply to us personally or by letter." We have been shown copies of other letters which corroborate the statements with regard to the good qualities of the thresher. The application of steam to agricultural instruments is effecting a revolution in farming, and we sincerely hope that this is as successful a beginning as it seems to be, of machines made on, and therefore specially adapted to, our coast. Our engraver has given in the cut a good general idea of the device; and for further particulars our readers may be referred to the manufacturer, Joseph Enright, of San José, California.



ENRIGHT'S CALIFORNIA STEAM THRESHER ENGINE.

◆

THE NEW YORK ELEVATED RAILWAY.—An accident has happened on this road, which will have the effect of making the public suspicious of its safety. To test its strength, a train loaded with twenty thousand pounds of pig iron was lately run over the track, and thereby several weak points discovered and strengthened. Another test was made by running a car carrying nearly twelve tons of iron, when the track gave way, precipitating the car to the pavement below. Fortunately a passenger car attached fell without overturning, and but one person was injured, and he not very severely. But the possibility of being dropped some fourteen feet upon a hard road will frighten passengers, and the chance of having a train come tumbling on wagons and pedestrians who may chance to be traveling on the public street will prejudice people against the project. The directors on the road, however, propose to immediately repair the broken span and have another test.

◆

MR. BIERSTADT, the well-known photographer of Buffalo, and a brother of Bierstadt the artist, has left California for the East. He has obtained a great number of fine stereoscopic views in various parts of the State—about seventy of which were obtained at the Yosemite. He will further increase his collection with views of all the principal points of interest on the line of the overland railroad. Mr. B. is accompanied on the trip by his brother-in-law, Captain Edwin Thompson, late of New Bedford.

◆

THE Canadian *Illustrated News*, published by G. E. Desbarats, Montreal, Canada, is one of the most welcome of our exchanges. Finely printed on tinted paper, beautifully and profusely illustrated, and containing much well-written matter, it is a great addition to the parlor table.

Communications.

Jottings in Santa Clara County.

[Written for the Scientific Press.]

Saratoga is the name of a little village scattered along a beautiful stream at the foot of the Santa Cruz Mountains, in the Santa Clara Valley, some ten miles west of San José. As the name appears to indicate, it is a watering place, or near one—the soda springs which produce the celebrated Pacific Congress Water.

The Springs

Are about a mile and a half above the village, in a broad, deep ravine or cañon, filled with magnificent trees that revel in the wildest scenes of undisturbed Nature; a beautiful retreat, one to be enjoyed and not to be forgotten. The hotel and several cottages near the springs were not occupied at the time of my visit, and why not was beyond my conception; for truly I know of no pleasanter resort. At the springs I found two men busily engaged in bottling the water, under a pressure of gas collected in gasometers directly from the spring. Mr. F. L. Darling, the conductor of this department, convinced me that there was no deception as to the genuine natural gases collected and used in putting up the water. As to the water satisfying thirst I am very doubtful. I was not thirsty when I commenced drinking of it; but one taste was so little gratifying that I continued pouring it down to the very limit of my capacity, the only obstruction to my appetite for it.

Caldwell Spring.

About one mile to the north of this spring, on the stock ranch of Mr. A. S. Caldwell, is a small spring, the water of which, to my notion, quite equals in excellence the Congress waters. It breaks out in a ravine through rock identical in formation with the conglomerate cement about the Congress Springs. No public mention has ever been made of Caldwell's spring, and probably not fifty persons even know of its existence.

New Almaden Springs.

I might add here that I also took occasion to visit the New Almaden Springs, where the "Vichy water" is obtained. In formation of surrounding rock, in appearance of spring and taste of the water, it exactly resembles the two previously described, only it lacks the strength and sprightly sweet *twang* or flavor of the Congress water. As my taste has never been vitiated by whisky and tobacco, I considered myself fully qualified to express an opinion. I found two men here who informed me that they were engaged in putting up "Vichy Water."

Bad Management.

To the north of Congress Springs are a beautiful range of rolling hills, admirably adapted to the cultivation of the grape, which are now laying nearly worthless for the want of culture. At Saratoga, where some excellent land is easy to cultivate and to irrigate, I saw a vegetable wagon from beyond San José, twelve miles distant, retailing garden vegetables, of all sorts. Even the farmers in San José valley, as a rule, buy the common vegetables that they might grow in abundance at their very doors, and that, too, with the time that many of them idle away or foolishly spend in town.

The Saratoga Paper Mill

Was erected about two years ago at a cost of some $50,000. It daily converts three tons of starw into 200 reams of paper, averaging twenty-eight pounds to the ream. The power is supplied by two of Hinkley & Co's Fulton Foundry Works engines. The pulp-room engine is a 75-horse power machine, and the exhaust steam cooks the straw. Two large boiler tanks, each holding three tons of straw, are charged alternately. It takes twenty-four hours to finish the steaming. The steam is supplied on a principle, and operates similarly to the automatic boiler. The process is a beautiful one. Four barrels of lime are used in this, which is termed the "bleaching process," at each charge. Hoisting works attached to a movable bottom, raise the bleached straw out of the tanks. It is then ground for four hours in the pulp troughs, of which there are two, gradually supplied with water till thorough maceration fits it for the

Machine Room,

Where it is evenly conducted to the cylinders. A 15-horse power engine drives the cylinders—a long row of them—and the other machinery. The exhaust steam supplies the cylinders with the heat necessary to dry the paper, which is finally wound upon bolts, to be again unwound and cut with a gauged machine into sheets, measuring about 20x30 inches, ready for wrapping paper.

Rye vs. Wheat Straw for Paper.

Mr. King, the foreman, informed me that he was paying $3.50 per ton for wheat straw, and $8 per ton for rye straw; and that he used the former only because of the impossibility to get sufficient of the latter. He had furnished several farmers this season with seed rye, and agreed to pay $8 per ton for the straw.

The Growth of Rye.

I have seen several of the patches of rye thus sown, and have noted the growth. That which was sown early stands six to eight feet high, on an average, and shows not the least sign of drouth. If it had been cut for hay it would have paid better than any other crop sown for that purpose. Indeed, rye makes good hay alone, and when mixed with barley and oats makes the very best of hay. I noticed particularly one piece plowed and sowed at the same time, and immediately alongside of a piece of wheat. The whole was put in late, but treated the same. The wheat will prove a total failure, by reason of the drouth, not standing above seven inches, on an average, blighted, and not fit even for hay. The rye stands five feet high, and promises an abundant yield of seed, and a fair quantity of straw.

Rye as a Grain

Is not much used for food on the Pacific coast; but it is certainly delicious, when mixed with corn meal and baked into a genuine "Boston loaf." For fattening stock it is very excellent, when mixed and ground with other grains, as wheat, barley, oats, peas, etc. One thing is sure, its growth is prodigious under favorable circumstances. It will also succeed where wheat will fail from drouth. For a general culture all over this State, it deserves more attention than it has heretofore received.

Pasteboard Manufactory.

Summerville & Co., of Saratoga, are erecting and have nearly completed a mill for the manufacture of pasteboard—the first mill of the kind on this coast. The capacity of the mill will be one ton of board per day. A water-power will be employed to run the machinery, with a 16-inch Jonville turbine wheel, under a pressure of thirty-six feet fall. A boiler will supply steam for the bleaching works similarly to the paper mill works. The pulp machine will prepare the bleached straw. No drying cylinders are employed, but a large yard is to be used in which to dry the board. I had always supposed that some sort of paste was used to stick layers of paper together in making pasteboard, but Mr. Sommerville explained that away. The right quantity of pulp is forced between rollers, to make the board the right thickness at one operation. Mr. Sommerville and his son, both intelligent mechanics, claim to be paper-makers of the fourth and fifth generations. Mr. S. told me, that when a boy, he used to make paper by hand.

This mill will be in operation about the first of June, and will be worth visiting. The board will be used for making boxes, etc., on this coast, and Mr. S. expects the demand to more than equal his supply.

No Chinese labor is used or desired in either of the paper mills here. This intention was emphatically expressed. He will prefer rye straw to wheat straw, and will give double the price in preference.

Miscellaneous.

There is a large stone flour mill in this place, but it is idle at the present time.

Mr. D. F. Hughes is building a chair factory on a small scale. He will use the native woods, which he says are unequalled for the purpose. I saw little else here worthy of note, but yet I observe a good opening for much improvement and enterprise, more particularly in the matter of cultivating the soil. S. H. Herring.

Letter From Bull Run District.

[Written for the Scientific Press.]

Editors Press:—This district is situated on the county line dividing Elko and Lander counties, some eighty miles to the north of Carlin. It is about fourteen miles square, is well provided with wood and water, and offers every facility for mining and milling. It has a dense forest of fine sawing timber, and the mountains, which are capped with limestone (although the original formation was slate and granite), are high and steep, and afford excellent opportunities for tunneling.

The veins run very regularly in a northerly and southerly direction, pitching to the east into the hill. They average all the way from six inches to twenty feet in width. The ores carry considerable base metal, principally lead, of which there are veins two feet wide which will give 90 (?) per cent. of pure lead. [Pure galena contains only 86.6 per cent. of lead.—Eds.] There are, as yet, no mills in the district. The Porter company have shipped to the Reno mill twelve tons of ore which yielded $300 per ton, and they will soon ship twenty tons more of a higher grade.

The snow is now rapidly disappearing from the mountains, and miners are coming in from every direction, prospecting for new mines, and opening out those previously discovered. Among the companies already at work may be mentioned the Porter, the Norwich, the Ophelia (which has ore which will yield about $800 to the ton), the Highland Queen and the Georgietta. The Found Treasure has been at work all winter opening out the mine, and has a tunnel about 150 feet long.

There are also placer mines in this district which are creating quite an excitement among the Chinamen, about sixty of whom came in last week. The gold is very fine and can be found in almost any place on the bottom and in the gulches, although not in very great quantities. I have taken out ten cents to the pan.

Altogether our prospects are bright, and there is every indication that Bull Run will be a most lively camp this summer in the way of mining enterprises. J. J.

Bull Run District, Nev., May 16th.

Determining Position by Telegraph.—Last night between 11 and 12 o'clock, the last interchange of signals between St. Louis and the observatory in Washington City, for the purpose of determining the longitude of St. Louis, was made. The signals consisted of a comparison of the local time of the two cities by telegraph. This is done by transmitting the beats of the clock or chronometer along the wires, and by this means a coincidence is established, and the accurate difference deduced. At the Washington observatory the pendulum of a large sidereal clock, by a simple but ingenious contrivance, is placed in direct connection, so that each oscillation breaks the circuit and is transmitted to St. Louis by a single tap of the instrument. The signals from St. Louis were somewhat different. Every fifth second of a solar chronometer was transmitted, and then every second, and lastly every tenth second each throughout a minute or more. Last night everything worked to a charm. The clattering tongues of the telegraph instruments were hushed for a time, and the steady beat of a sidereal pendulum swinging in Washington—a thousand miles or so away—was the only sound heard. Prof. Harkness, of the Washington University, and who has learned to work the telegraph tolerably, was present in the observatory, and sent and received signals. Some little interruption was caused by the curiosity of telegraph operators in West Virginia, who couldn't for the life of them make any sense out of the clock-beats, and wanted to know what it all meant.—*St. Louis Republican, May* 1*st.*

* * *

The Parker Steam and Air Engine.—*The Engineer* describes this as a form of aëro-steam engine, involving the same general principles as Warsop's. In this latter engine, air is forced by a pump through a coil of pipe exposed to a high temperature, into the water in the boiler. In Parker's engine, the air is forced directly into the steam pipe leading to the cylinders, and is therefore no hotter than the steam. The result of the working trial witnessed by the journal above-named was favorable.

Pavements and Sewage.

This subject, so very important for San Francisco, although receiving so very little attention, was considered at the meeting, May 18th, of the New York Society of Practical Engineering. The writer of the regular paper (J. Harrison, Esq.) treated mainly of the systems of sewage and street construction proposed or tried abroad and their adaptability to the needs of New York and other American cities.

London has about one thousand miles in all of sewers properly so called, besides nearly an equal length of branch drains or pipes. Some of these have been in existence since the invasion of Britain by Julius Cæsar; but before the beginning of the present century the sewers were used only to drain off the surface water. The deposits of the cesspools were carted off for manure while the liquids oozed into the sandy soil. When the city spread upon the adjacent clay lands where this absorbtion became impossible, the sewage was turned into the sewers, as is now the almos universal practice. The enlargements that resulted, and the new sewers that were constructed, were so poorly designed, however, that their outlets are mainly below high-water mark. As a consequence, when the tide rises, it carries sand and dirt into the sewers to choke them, and drives the polluting gases back, so that they escape into the air through traps and sinks. Analysis shows the composition of these gases to be about 70 per cent. of light carburreted hydrogen, 16 per cent. of carbonic acid, 10 per cent of innocuous nitrogen, and the rest of hurtful compounds, such as sulphurreted hydrogen—a poisonous emanation, which acts directly upon the blood, turning it black, and a peculiar organic vapor which excites putrid diseases in the human system. One gallon of common sewage will evolve from one and a quarter to one and a half cubic inches of these noxious gases per hour, and the putrifying process may continue a month or more. Many plans have been proposed to remove these gases from sewers by means of a draft, but they have all proved inefficient and costly. To remedy the manifest defects in the London sewers, engineers proposed, a number of years ago, to build a second or sub-system below the present one, from which the sewage could be drawn by steam pumps; the present or upper sewers could be used as forrmerly for draining surface water, while the new could be devoted exclusively to sewage, which when pumped out, could be carried in pipes to fertilize agricultural lands in the neighborhood of the city. The advantage of this last was illustrated by a sketch of the manner in which the same thing has been done in the vicinity of Edinburgh, in Scotland. The sewage of the city, applied to worthless fields at an annual cost of about half a guinea per acre, in the space of twenty-five years brought them up to a value of five hundred and twenty pounds sterling per acre, yielding grass in the cullings of seven months, amounting in the aggregate to more than a growth ten feet in height. The writer claimed that the proposed improvements for London were equally applicable to New York with its two hundred miles of sewers, possessing, especially in the low-lying parts of the city, the same defects as those of the English capital. With reference to the construction of pavements, their impermeability to gases from below and liquids from above, and also the essentials of durability, smoothness, foothold for horses, and ease of purification, the writer considered the concrete and wooden pavements, tried separately and condemned in England many years since, but which the writer believed could be so combined as to constitute a practically perfect pavement, the concrete serving as an impervious foundation for the wooden blocks, which should be thoroughly impregnated with some antiseptic and preservative substance.

* * *

How to Kill a Dog.—It sometimes happens that it becomes necessary to kill a favorite pet, as a dog, for instance, where the owner wishes to get rid of him in the easiest possible way, so as not to be either a witness or accessory to the pains and barbarism of shooting, or the spasmodic effect of strychnine. Mr. Eben Wright, Dedham, Mass., has communicated to the *American Agriculturist* a method which *he* has adopted, and which he recommends to all who may be as sensitive as he is about such things (and we are happy to say that such people are rapidly increasing in numbers). This gentleman laid his dog on a blanket, in a box, and after pouring upon him about four ounces of chloroform, covered him with another blanket, closed the box tight, and his pet *went to sleep.*

Mechanical Progress.

The York County Iron Ore.—The *U. S. Railroad Register* does not endorse the rather extravagant statements in reference to these Pennsylvania iron beds, which have been going the rounds,—although it considers them valuable. "They are only peculiar in being very easily crushed and washed to a pure magnetic oxide black sand, resembling that found and used on the shores of the St. Lawrence, below Quebec; and in fact they are the same ores, lying in the same rocks. In the puddling furnace, this ore carries up the quality of the iron, toughens and hardens it, and gives it a steely nature; but it can't pretend to make it into 'good merchantable steel.' Now and then a batch of blooms will come out so nicely carbonized that very respectable chisels can be made of them. Magnificent rail bar iron has been thus produced. With Whelpley & Storer's *high speed fuel dust fan and tuyere* furnace arrangement (getting up a manageable heat as great as any that Siemens can get up in his costly and cumbersome regenerating furnace) we expect from it even the direct production of shear steel, if such be a possible achievement of man. But at present the York county ore beds are simply and solely valuable, as being extensive deposits of *sand mixed with crystals of magnetic iron ore*, free from sulphur, and so loosened by the dissolving rain drainage of ages, as to be easily worked and washed, and offering a first-class *mixture* for the use of the furnace man and of the puddler."

Diamond Cutting in Boston.—The *Manufacturer and Builder* says that Boston diamond cutters are coming into strong competition with the Amsterdam workmen who have so long held the monopoly in that business. "The firm of Crosby, Morse & Foss, are the pioneers, and have made improvements on the method employed. In place of using the horizontal wheel on a perpendicular shaft, set in a ponderous wooden frame, a small iron-topped table is employed, with a solid stanchion projecting upward from the center, and reaching over to form the upper bearing of the perpendicular shaft, which is provided with a lower bearing beneath the table. The wheel is fixed in the center to revolve horizontally on a level with the surface of the table. Thus the steadiness, so absolutely necessary, is obtained without recourse to bulky framing, and this improvement has already been copied in Europe."

New Pumping Engines.—We clip the following from the correspondence of the *Iron Age*, May 19th: "The Philadelphia Hydraulic Works have lately completed a peculiar engine for the water works at Newcastle, Delaware. The machinery consists of a pair of pumping engines, side by side, running in unison, without shaft or fly-wheel. The steam extensions are peculiar, each embracing, under cover of what appears to be a single cylinder, a distinct pair of cylinders, one being only one-third as large as the other. The steam is used first, high pressure, in the smaller, exerting a second force, low pressure, upon the piston of the larger. A pair of double-action horizontal air pumps, situated between the engines and driven by their motion, create a continuous vacuum upon the exhausting ends of the low pressure cylinders. This combination results in the consumption of but a nominal amount of steam. This is a especially new wrinkle in steam machinery."

Changing Horizontal to Vertical Rotation.—A Belgian has invented a new method of transmitting the motion of the horizontal vane-shaft, in a windmill, to the vertical working shaft. It is a steel spiral a foot in diameter, of some fifteen turns, and attached by its two ends to the two shafts respectively. These shafts have, upon the ends to be attached, iron caps of the same diameter as that of the spiral. The steel ribbon of which the spiral is made is two inches in diameter and from one-eighth to one-fourth-inch in thickness.

Petroleum Burning Locomotives.—Two locomotives on the Paris-Strasbourg Railway have been fitted up with Deville fire boxes and draw heavy freight trains. They consume from 3½ to 5 kilogrammes for every kilometer of road—*i. e.* 12 to 18 lbs. per mile; no smoke; no waste; and no sulphurous gases and odors in the tunnels traversed.—*U. S. R. R. Register.*

Steam from Gas Fuel.—The India Dock Wash-houses have adopted Jackson's patent for the hoisting works. The London *Mining Journal* thus speaks of it:

"The boiler, which is of 2-horse power, and occupies a space only 3 ft. square, is heated entirely by gas, the steam rising between 6 and 7 lbs. per minute, and affording an abundance of power for the steam crane, which has a cylinder 6 in. diameter and 10 in. stroke, working a cage 7 ft. 1 in. by 5 ft. 6 in., and capable of holding upwards of 20 full-sized chests of tea. The cage, however, is seldom loaded in this manner, it being found that greater expedition and economy of labor result from running the chests direct into the cage, on the ground floor, without removing them from the trucks on which they are taken out of the vans. The cage and trucks are raised to the floor required, and forthwith wheeled to their allotted bed. The system requires no stoker, brickwork, chimney, fire-bars, nor smoke-consuming apparatus, whilst with regard to efficiency, safety, and cleanliness it is without equal. The cost of gas for cranes of this size while at work is found to be about 6d. per hour. Wherever an ordinary gas supply exists the gas-boiler can be satisfactorily employed, and where the use of steam-power is required only occasionally gas generated steam would be economical, whilst that generated in the ordinary manner would be altogether inapplicable."

Cylindrical Cars.—A Glasgow inventor has designed a wrought-iron railway car of cylindrical form, which is described by *Engineering*: "The plates, of wrought iron or steel, are riveted on annular ribs, which act as ducts for the admission of air at the top, carrying it below the floor, and discharging it there, to rise up into the body of the carriage by apertures in the floor. The cylindrical form gives strength to resist side pressure, while longitudinally the carriage body is stiffened by angle-irons and roof plates, as well as by floor supports and semi-tubular strips. In the event of a collision, these bracings and stiffening strips will offer more resistance than an ordinary wooden carriage, while there is no danger of splinter from the iron. The plates being riveted from the outside upon the ribs would naturally start outward, and consequently from the passengers, exposing them to less danger." The heating apparatus is suspended beneath the carriage and the warm air conveyed through pipes. The weight and cost are said to be less, and the carrying capacity greater, than those of the cars in ordinary use.

Compound vs. Single Engines.—B. W. Farey, whose name is often mentioned in connection with experiments of this kind, writes *Engineering* of some new comparative trials made by him, and closes thus: "I would mention that it is generally believed that the friction of the compound engine is greater than the single cylinder; from direct experiments, this I find to be the reverse, as the pistons do not require to be so tight in the cylinders as in the single cylinder engines, because the difference of steam pressure is not so great, and any steam escaping the small piston does not go direct into the condenser, but has to escape the low pressure piston; and consequently in practice from this and other advantages, the compound engine (using of course the same pressure of steam in the cylinders) is found to run much longer without repairs than the other class."

Compressed Air for Street Cars.—A company has been organized in New Orleans for the application of compressed air as a motive power for street railways. For economy in weight, the cylinders into which the air is compressed are to be made of *paper*. A trial cylinder of this kind has borne a pressure of three hundred pounds to the square inch without yielding. A car fitted up for experimental purposes, with leaky iron cylinders (weighing 1,600 pounds) made three miles and a half in seven and a quarter minutes, carrying twenty-eight passengers. The cylinders are to be on the top of the car, and are to be charged at the depot by means of a stationary steam-engine.

Fan-Blowers.—B. F. Sturtevant,—says the Boston *Commercial Advertiser*,—is turning out 2,000 of his fan-blowers per year. This invention is covered by eighteen patents, and two more are pending. He employs over one hundred hands in the manufacture of these machines and others of his invention.

Scientific Progress.

Ammonium and Hydrogenium not yet Proved Metals.

Prof. C. A. Seely read a paper at the meeting of the Chemical Section of the New York Lyceum, on May 9th, in which he showed that the amalgams, so called, of ammonium and hydrogenium are simply metallic froths, and consequently these substances are not proved to be metals. An abstract of the paper is given in the *Chemical Repertory*, from which we quote and condense:

"The author considers the so-called ammonium amalgam to be a mechanical or physical mixture of liquid mercury with the gases ammonia and hydrogen, and that its semi-solid consistence is due to the mixture having the nature of a froth. When sodium-amalgam is brought into a solution of sal ammoniac (the ordinary method of preparing ammonium amalgam) the chlorine combines with the sodium, and the residue of the sal ammoniac is set free all over the surface of the mercury. The particles of the mixed gases adhere to the mercury, and by reason of the movement bringing to the surface fresh mercury, they become enfilmed and carried inward, until the mixture becomes a homogeneous froth. The principal considerations by which this view has been reached, are as follows:

1st. The volume of ammonium amalgam is inexplicable in any other way. * *

2d. Mercury has a mirror-like surface, while ammonium amalgam has a comparatively whiter and more dead surface. * *

3d. If ammonium amalgam be subjected to varying pressure, its volume changes apparently in accordance with Mariotte's law of gaseous volume. * *

The so-called ammonium amalgam is, therefore, not an amalgam at all; ammonium is not proved to be a metal, and if it be admitted that the monatomic radical really exists in ammonium amalgam, it is neither a solid nor a liquid, but a gas.

The considerations regarding ammonium amalgam are equally applicable to Loew's hydrogenium amalgam; both are only metallic froths. The expansion of palladium observed by Graham, on its absorption of hydrogen, is probably analagous to the case in question. * * Many have erroneously supposed that hydrogen was conspicuous in its capability of being absorbed by metals, and thus have more readily been infused with the hydrogenium theory. Oxygen has an eminence over hydrogen in that property, and yet no one has a theory of oxygenium. Iron absorbs carbonic oxide, but no one is bold enough to suggest that carbonic oxide is a metal."

Age of Nova Scotia Limestones Determined by the Microscope.—We take the following from an article by H. Y. Hind, M. A., in the *American Journal of Science and Arts:* "In the autumn of 1868, Dr. Honeyman, then engaged on the geological survey of Canada, discovered on the Gulf coast of Nova Scotia, in the Arisaig district, syenites, diorites, and crystalline limestone, with serpentine, which he supposed were of Laurentian age. Specimens were sent to Montreal for examination, and instructions were given by Dr. Hunt, who shared Dr. Honeyman's opinion, to the lapidary, to prepare sections of the serpentinous rock, for microscopic examination. By some mischance the specimens remained unexamined until quite recently. When submitted to the microscopic test, the *Eozoon Canadense* was distinctly seen, and Dr. Dawson has confirmed the observations. This not only affords most satisfactory testimony to the existence in Nova Scotia of the Laurentian limestones, but it enables geologists to recognize the truth of Dr. Honeyman's opinions, although by an accident these opinions were not made known or confirmed until after the publication of my Report."

Science does not Deal with Abstractions.—The discussion between Professors Walling and Van der Weyde continues. We give a single paragraph from the latter's last: "I have come to the conclusion that the true road to progress in the science of physics lies not towards abstract hypotheses of caloric fluids, luminiferous or electric ethers, or forces capable of moving bodies, all having an independent existence in space. The index-hand of modern science points in a very different direction; namely, towards the study of *matter* and *motion of matter*, and nothing else, dropping all metaphysical assumptions of which matter is not the basis."

Figures Produced by the Electric Spark.

Prof. Eli W. Blake, Jr., of Cornell University, gives in *Silliman's Journal* for May a method of producing by the electric spark figures similar to those of Lichtenberg, which were due to the position taken by light particles of dust upon an electrified surface. We quote:

"Prof. Rood has shown that figures entirely similar in form are produced, when the spark is allowed to fall on the sensitized collodion film of an ordinary photographic plate, and the latent image is developed in the usual way. The method I have to describe consists in throwing the discharge upon the surface of a fusible non-conducting body. If the body be near its fusing point the figure appears at once,—if cold, a latent image exists which may be 'developed' by heat. The non-conducting surface is prepared by coating a plate of metal with an even film of pitch. Pieces of sheet-tin, three inches square, coated with films of pitch of a thickness varying between 0·01 and 0·02 inches, were used in most of my experiments. The pitch was the ordinary commercial article, freed from sand, fragments of bark, etc., by being melted and strained through a muslin bag. Shellac, rosin, Burgundy-pitch, bees-wax and Canada balsam were in turn tried as substitutes for pitch, but with unsatisfactory results. * * The discharge having taken place, the plate may be removed for development. This process consists in gradually warming the plate over a lamp. The metal side must be presented to the lamp, as the slightest touch of a flame on the excited pitch instantly dissipates the electricity. At a certain temperature (in my experiments about 60° C.,) the figure will begin to appear, and in a few seconds the development is completed. The plate being now allowed to cool, the figure becomes permanent. If the plate be overheated the figure is destroyed. It may be instantly obliterated by exposure for a second to the naked flame, and the plate may then be used again. * * An interesting fact, in connection with this subject, is the length of time that may elapse between the reception of the spark by the plates, and the development of the figure. Several plates were charged in immediate succession, and developed one by one, at intervals of two hours. The last, developed after twelve hours, showed hardly any loss in depth or sharpness, although the weather was damp and unfavorable. Of another series the last, developed after *seven days*, still came out distinctly."

Phosphorus Essential to Organization.—The following is from a paper on nutrition read by Dr. Ott before the New York Liberal Club, May 4th: "Among all mineral ingredients, none are more especially attracted and retained by the tissues of the animal body than the phosphoric acid and the phosphates. The higher the organization, the larger the proportion of phosphoric acid and its compounds required. It has been found by Bousarelli that among all the organs of the body, the brain contains by far the largest amount of phosphated fat, the amount of phosphorus being twice as large as that in the muscles. Phosphate of lime is present in every tissue; moreover, all secretions from the blood, which are distinguished by their plasticity, exhibit phosphates; and, according to some investigators, these salts are required to supply the first basis for a new tissue, even in the case of those organs which subsequently exhibit an excess of carbonate of lime."

Antiquity of the Table Mountain Remains.—In a recent letter to the editor of the N. Y. *Mining Journal*, Prof. Whitney says that the mammalian remains so far identified as underlying the basaltic lava of Table Mountain, bear a closer relation to those of the rocks classed as Miocene by Leidy and Hayden, than to those of their Pliocene. The fact that all are of extinct species, together with the enormous denudation in that region, indicates the great antiquity of the strata. He adds that "the evidence of the vast antiquity of the human race in California is gradually accumulating. You may look forward to an interesting chapter on that subject in the next volume of the Geology of California."

Extracts of medicinal plants are now made with the bi-sulphide of carbon by M. Lefort.

Mining Summary.

The following information is gleaned mostly from journals published in the interior, in close proximity to the mines mentioned.

California.

ALPINE COUNTY.

M. C. Tunnel No. 3.—*Miner*, May 21st: The working of ore at Reno mill, gave a return of $44.74. This is ore out of the tunnel 100 feet from the east wall, where the main deposit is known to lie.

Large loads of lumber, track iron, powder and other supplies pass through Monitor for the Leviathan.

Scandinavian Canon.—*Chronicle*, 21st: Since the purchase of the Buckeye 2 mine by the Exchequer Co., and the succesful working of its ore, the mines in the cañon have been attracting unusual attention. There are several claims which are known to be good. Most of the work now done here is paid for by New York and London capitalists. The claims held by San Franciscans are allowed to remain unworked.

Exchequer.—Work progresses. The road is finished, and grading going on for a large boarding house for the men.

Adolphus.—This is a claim relocated in Scandinavian cañon. A shaft is being sunk on the ledge, and the ore now coming out looks well, showing ruby.

AMADOR COUNTY.

Kennedy.—*Ledger*, 28th: We learn that the Co. have made a rich discovery. Some time ago they let a contract to sink their shaft 100 feet deeper, and on Tuesday last, 50 feet from where they commenced sinking, they struck a four-foot vein of the richest rock we have looked upon for many a day. The specimens exhibited are completely studded with free gold and rich sulphurets.

BUTTE COUNTY.

Quartz.—Oroville *Record*, 28th: Mining in Butte is beginning to look up again. We understand that in addition to Mr. Halstead's mill now worked at Oregon City, the Derrick mill will soon be started again.

Work Commenced.—The work on the canal of the Spring Valley Mining Co., which is to carry water into Cherokee, has commenced in earnest. Seventy laborers passed through town on Tuesday to commence.

CALAVERAS COUNTY.

Palomo.—*Chronicle*, 28th: Work is progressing favorably. The new battery of 20 stamps will be in operation in a couple of weeks. The most of the machinery is already on the ground.

Petticoat.—We are informed that work will be speedily resumed upon the mine.

Machinery.—The machinery for the Hepburn mill at Railroad flat, which is being remodeled by Mr. Burr, has arrived. The mill will soon be in operation.

Items.—The Harkins mine, Monitor district, probably the richest gravel claim in the country, continues to pay fabulously. ....Mullen & Co., same district, are daily expecting to strike the channel; their tunnel is 800 feet in length, through bed-rock. ....Paul & Co. are industriously at work. ....Whittridge, at the Junction, is at work....The indefatigable Shaw looks contented—indications of healthy sluice-boxes....Brackett & Co. struck it some time since....The Union shaft boys will commence taking out pay gravel again the first of the week.

EL DORADO COUNTY.

Gold Dust.—Placerville *Democrat*, 28th: During the week there has been shipped through Wells Fargo & Co., $15,690.

Georgetown.—Cor. of same: The negotiations for the sale of the Eureka mine fell through. Work on the claim has been commenced, and yesterday the mill was started, the determination being to fully prospect the claim.

NEVADA COUNTY.

Pennsylvania.—*Transcript*, May 25th: The water is to be pumped out, and there is every prospect that the mine will soon be yielding again.

Items from the Ridge.—Same of 26th: The English Co., on Buckeye hill, Sweetland, cleaned up $15,000, the proceeds of a short run....The Buck and Breck claims, owned by a Chinese Co., have been paying big, and the Chinese have sunk all the money for the purpose of extending their operations. The claim is nearly worked up to their line. The company is negotiating for the purchase of one-half of a mile of gravel claims on Shady creek.

North San Juan.—Cor. of same. There are only three companies washing on this hill at present, Foster & Co., Bsech & Co. and Bowen & Co. The Empire company will commence in a few weeks. The supply of water is diminishing. The rumors that the Eureka Lake Water Co. and the North Bloomfield Mining and Ditch Co. were negotiating for a consolidation are probably groundless, although such a thing is to be desired. At Sebastopol, the American Co. stopped washing four weeks ago, owing to the high price charged for water. They have now determined upon building a ditch of their own. The same of 29th says the ditch will start above Cañon creek, and pass through the mining region in the neighborhood of Badger hill, Cherokee, North San Juan to Manzanita hill, ending in the American Co's claims. Its estimate cost is $150.000.

Items.—*Gazette*, 25th. W. C. Stiles is crushing 45 tons of rock from the Mulberry ledge, on Gold flat. The rock contains no sulphurets, and will yield about $13 a ton. ....Same of 28th: A number of the best claims on Diamond creek suspend operations for the season, on account of lack of water. The Omega Ditch Co. are running their ditch full, but are using it all themselves.

Eureka Mine.—Grass Valley *Union*, 25th: Yesterday was the regular semi-monthly melting day, and gold to the value of $28,500 was put into bars. This was from a run of twelve days of the mill, and is independent of sulphuret workings. The Eureka has more than paid its $2,000 per day for the last twelve days.

PLACER COUNTY.

Colfax.—*Stars and Stripes*, 26th: The "Rising Sun" mine is doing an average yield of $2,000 per week. The ledge is very narrow, yet immensely rich. The sum of $15 per foot was offered last week. The Montana Co. have struck their ledge at the depth of eighty feet. It is about eight feet wide, and is excellent looking rock. The Ranger Co., after tunneling through hard rock for two years and a half, expect to find their ledge within a month, at the depth of two hundred and fifty feet. This tunnel will prospect five or six claims on the same ledge,

St. Patrick.—*Herald*, 28th: Rumors have been floating around that Mr. Eston has sold the mine for $45,000. Capitalists from San Francisco have been up, and on Thursday they telegraphed Mr. Eaton to come to the bay.

Another Good Mine,—F. Simons and partner crushed twenty-five tons of quartz this week, which yielded $900.

Evening Star.—The engine and hoisting works have been put in motion, the shaft pumped dry, and good quartz is being taken out. The mill will be in readiness soon.

Colfax.—Cor. of same: The eastern extension of the Rising Sun is known as the "Hazel Green." They are in great glee over their propects.

Ike Herrington & Co. have been sinking a shaft, and have reached the depth of 52 feet. Their ledge is three feet thick, and shows some free gold.

PLUMAS COUNTY.

Taylorsville.—Quincy *National*, May 21st: The miners of Light's cañon are all making good wages—say five dollars per day to the man.

SISKIYOU COUNTY.

A Chunk.—Yreka *Union*, May 27th: Romine & Co., of Humbug, found one day last week in their tailings, thrown out last year, a chunk of gold weighing eleven ounces.

Scott Valley.—Shaw & Co., Smith & Co., S. Mooers, and Howard & Co., of Miggingsville, are working their claims with flattering prospects. Wright Bros. and J. Young, of Oro Fino, are working a large number of hands, night and day. Patterson creek, though located but last fall, is almost entirely claimed. Burge & Co. struck dirt that prospected three dollars to the pan, while running their tail-race. Carpenter & Co., Tuttle, Horn & Co., Swan & Co.. and several other parties, have their claims opened. Coalman, Reynolds & Co., and others, on Rattlesnake, are receiving good pay. Bailey & Co., Short, Duff & Co., Hooper & Co., and Star & Co., of Indian creek, are getting fine prospects; McAdam's, Deadwood and Cherry-creeks are holding their own.

SIERRA COUNTY.

Scales' Diggings.—*Democrat*, 26th: Cox and Williams sunk a shaft, have a tunnel run to it, and are now prepared for work. They have an engine on the ground. Mr. Van Rensalear, of Brandy City, proposes to bring in big Cañon creek, by means of a ditch and flume. Those who have water and grade are doing well. Mr. Boyce and brother have done finely. At Council hill they were taking out first rate pay. The claims at Union hill, owned by Miles & Co., are still prosperous.

Iowa.—This company, on the ridge five miles below Port Wine, have a shaft 160 feet to the bed rock, and 26 feet of gravel, all containing gold. They have run a tunnel 1,160 feet, tapping the shaft, through which they expects to drain the ground. They have an engine and expect to start before the 4th of July.

Fir Cap.—This Co. have run a tunnel 1,460 feet, and have now one foot and a half of gravel at the top of the tunnel. This prospects finely, and they expect soon to commence taking out gold.

Poverty Hill.—A San Francisco Co. have commenced a tunnel, to be 6x7 feet in the clear, and 1¾ miles long, which will drain a large amount of ground, and through which claim-owners will be allowed to work for a consideration. Another good chance for capitalists is the bringing in water from Slate creek. It would pay.

Monumental.—It is reported that this company have found another rich deposit in their lower tunnel. We heard that they had taken out yesterday several thousand dollars. This is the Co. that took out the 106-pound lump last summer.

Items.—*Messenger*, 28th: Water is failing at Eureka, and one company has cleaned up....The Reis Bros. will put up new mills this season....The Cox tunnel, near Poverty Hill, is finished....Parker & Co., of Slate ravine, took out a nugget of gold and quartz valued at $58....The Dreadnaught Co. have been crushing rock at the Docilo mill for several weeks.... The owners of the Highland Mary have started a tunnel at Wahoo, on the opposite side of the ridge from Port Wine.

Monumental.—The new strike gave out seven or eight thousand dollars in one day. The tunnel where they have struck pay is 200 feet lower than where they were working last season. This is not a quartz ledge, but a seam of oxidized sulphurets. The company are working a chimney, and where they took out pay last summer it pinched out to a mere streak.

SAN DIEGO COUNTY.

Julian District.—Los Angeles telegram, May 21st: The leads being developed are the Washington, Mount Vernon, San Diego, Lincoln, High Peak, which show better defined ledges, widening on sinking. On all of them shafts are down from 20 to 60 feet. Seven thousand dollars has been refused for the Mount Vernon.

TRINITY COUNTY.

Not Worked Out.—*Journal*, May 28th: John Keach and a Portugese came to Weaverville, Thursday, from Pony creek, bringing with them a gum-boot leg filled with gold. One hundred and twenty ounces of the largest specimens were on exhibition at the bank that afternoon. Among the lot were two thirty-five ounce pieces. During the last two weeks, John and his hired man took out nine hundred dollars.

New Diggings.—There is some excitement on New river, caused by the discovery of a channel on the east fork which prospects well.

Arizona.

Walker District.—Prescott *Miner*, May 14th: C. Y. Shelton, owner of the Vernon lode, got $31 one day recently, rocked out of decomposed ore.

The New Mines.—Correspondent of the Amador *Ledger*, dated Fort Selden, New Mexico, May 4th: I can only say it beats all yet discovered for extent and richness. There is one lode, the Capitol, which is 40 feet above the surface, 200 feet wide, and assays from $20 to $12,00 per ton. There is another, the Leo, which is at least 400 feet high, 2,000 feet wide, and assays from $40 to $1,800 per ton; and there are a great many more. I saw assays from different leads running from $20 to $1,980—making an average of $680 to the ton—and all top rock. There is not a shaft sunk over six feet yet, and none of the rock assayed was taken from below the surface. Now for the disadvantages: In the first place, water will have to be brought from San Sumon Senaga, 32 miles, in iron pipes, and raised 900 feet. Wood will have to be hauled 40 miles. There will have to be at least a million and a half of dollars spent before the mines can be worked to advantage. The country is taken up for miles.

Colorado.

Items.—Central City *Herald*, May 25th: M. B. Hayes' mill is crowded with ore from the Roderic Dhu and the Dead Broke lodes. Mr. Hatch's 12-stamp mill will soon be running on ore from the Anoka lode. A 4-inch streak of this ore assays $583 to the ton. ....At the Coaley business is lively, and the daily yield 8 tons of first-class ore. ....In the Consolidated Gregory there is a body of water 300 feet long and 200 feet deep. In the Black Hawk twice as much. The Briggs and Smith & Parmelee mines will be filled in a few days. In the Gregory the ore is very rich. The run cleaned up 13 ounces to the cord....J. B. Plummer is running his mill on ore from the Niagara lode in Russell....Phillips, Snowdon and Gleason are putting up an 8-stamp mill above the Illinois lode....Bela Buel will start up the Illinois mill....Mr. Hardesty has started up his new mill in Nevada, and Mr. Chatfield is fitting up the old Boston mill....The Prize lode is paying big.... Sullivan and Wheeler are preparing for extensive operations on the Roderic Dhu.

Pewabic.—*Register*, 25th: E. S. Perrin is working this mine again and getting 46 ounces per cord.

James Creek.—Boulder *News*, 18th: J. Whoosley is running Strock's arastra on ore from the Golden Clay lode....John Keen is fitting up Batchelder's arastra to run on ore from the Wabang lode. This lode has opened up nice....John Virden is getting his arastras ready to run on ore from the American....J. C. Jencks is mining at the mouth of Hill gulch. He is down to the bed rock, and has splendid dirt.

Linn Tunnel.—Georgetown *Miner*, 19th: We learn that work will be recommenced in a few days and pushed vigorously.

Terrible.—This morning a bar of bullion, weighing 1,065 ounces and valued at $1,108.46, in coin, the product of Terrible ore, worked by Huepeden & Co., was shipped.

Montana.

Rocker.—*New North-West*, May 20th: There are 150 men in the vicinity—100 working day and night while water is plentiful. The ground is paying from wages up to $50 per day.

Henderson Gulch.—There are 80 white and 45 Chinamen in the camp. This year there will be good water until July. Work began April 16th, and more money has already been taken out than in 1869. The claims are running night and day, some running three eight-hour shifts. Wages for eight hours are $5; ten hours, $6. Woodlock, Butler Barmingham and Hennessy are taking out $250 to $300 per day. On No. 3 the McPhail Bros. are taking out $30 to the hand. Davis, Terril & Co's bed-rock flume was cleaned up with good prospects. Robt. Ferguson, in running a cut for his good ground, found $9 to the hand in his boxes. The gulch claims will average $13 to the hand. The most of the ground was stripped last winter. The weekly yield of the camp is not far from $7,000. On Harvey creek 16 men are working a bed-rock flume. It is yielding $20 to the hand.

Boyle's Gulch.—*Independent*, May 21st: The claims have been laid over until the 15th of August. A ditch three miles in length will be dug.

Cable.—The new steam hoisting and pumping machinery is a success, and the main shaft is progressing favorably. The Tunnel Co. intend in a few days to resume operations with a large force.

Georgetown.—Jameson and Co. are mining upon an extensive scale. Ten feet of waste dirt is ground sluiced off, and the balance shoveled into sluices. They have erected a flume one-half mile in length.

Pipestone—The following companies have good ground: McDougal & Co., Wood & Belcher, C. Cook & Co., George Worthington, and Mr. Miliner. Some good mines have been found on the Big Pipestone, but the high water has prevented work.

Clipper.—*Times*, 18th: J. Wysnt is getting six ounces per ton in his arastras.

Wigwam Gulch.—The water has fallen and the miners are all at work.

Philipsburg.—Cor. of Helena *Gazette*, 23d: Merrill & Ullery have got their main shaft on the Western Comanche lode down seventy feet, and are taking out some of the richest ore that ever came from this mine. Our Camp creek furnace is nearly completed. The Speckled Trout lode is one of the best in the Rocky mountains. The Yankee Charley Co's shaft is down 114 feet.

Diamond City.—The water has flooded all the claims in Confederate gulch, and driven the miners all out. The shafts are full of water and the drifts have caved. About 2,000 inches of water are used in hydraulic mining on Boulder bar, Montana gulch, Greenhorn and El Dorado bar, which all promise well, especially the latter. Metcalf, McGregor & Co. are moving the gravel out of Montana gulch at a great rate, using 400 inches of water.

Gold Creek.—One company made five days run and cleaned up $1,996,54. Several more will clean up this week. There are three large ditches, but not half enough water, and many claims will be laid over.

Nevada.

COPE DISTRICT.

New Ledges.—*Independent*, 28th: On the 6th, three miles west of Mountain City, Pressnater & Co. discovered a silver ledge, showing splendid prospects. The ledge on the top is six inches in width; at the depth of 17 feet, 13. The company has already taken out two tons of ore, which will be shipped to San Francisco for reduction.

John Upton discovered a new ledge, which has been named the Ada Gassage.

HUMBOLDT.

The District.—*Register*, 28th: At Humboldt City there are several companies at work, and prospects better than since '63. The boys in Florida cañon are driving with energy. Alpha mine is looking finely.

Battle Mountain ore and bullion shipments are increasing,

Doing Well.—The Marysville *Appeal* of 26th says that John C. Fall is now the sole owner of the Arizona mine in Humboldt, Nev. Last year he took out about $500,000 and he expects to take out at least $1,000,000 the present year. He has from fifty to sixty men employed.

REESE RIVER.

Rich Strike.—*Reveille*, 25th: A streak of ore, about 4 inches wide, of unparalleled richness, has been struck in the Oregon mine of the Manhattan Co. Superintendent Frost thinks it will mill at the rate of $2,000 per ton.

WASHOE.

Outside Claims.—*Enterprise*, 29th: Much more attention has of late been paid to claims off the Comstock. About Silver City a large number of claims have been opened which have been idle for years.

Hale & Norcross.—Yielding daily 160 tons, 50 from the 175-foot level. The development at the 1200-foot level is the most satisfactory and encouraging on the line of the Comstock. Excavations have been made in this body of ore, showing it to be of immense extent.

Bullion.—The north drift at the 500-foot level has not disclosed any favorable features. The arrangements are being made to resume prospecting at the 1,400-foot level.

Chollar-Potosi.—The daily yield is 170 tons, averaging $50 assay.

Sacramento & Meredith.—The water from the Allen shaft has not proven sufficient to supply the battery. No difficulty has been encountered which cannot be readily overcome.

Belcher.—Daily yield, 70 tons; average assay, $37. The main source of supply is from the 152-foot level and above it. A good body is also developed above the 262-foot level in drifting south. It assays well and is eight feet thick.

Ophir.—The tunnel has not yet reached the west wall, nor revealed the existence of any ore at the point where it cuts the lead.

Gould & Curry.—About 50 tons per day is being extracted, showing an average assay of $40.

Crown Point.—The old upper workings yield 65 tons per day of low-grade ore, which is shipped by railroad to mills on Carson river.

Daney.—The east portion shows improvement, and the west breast looks well: The ore is of low-grade but can be milled profitably.

Virginia Consolidated.—The tunnel west from the shaft at the 500-foot station is in 375 feet. The water was somewhat increased.

Sierra Nevada.—No new development. The supply of ore is ample for the mill, and could be greatly increased if desired.

Sutro Tunnel.—The tunnel is in 1,117 feet. The ground remains about the same.

Resumed.—Work has been resumed on the old Solferino mine, which has not been worked for several years, owing to the unsettled condition of the title.

Imperial-Empire.—Gold Hill *News*, 28th: No ore as yet developed in the Holmes ground by the drift from 1,100-foot level. They are now drifting southward.

Yellow Jacket.—The rich new body of ore at the 900-foot level, breasts out 60 feet in width, with no wall as yet. It is the best and most extensive deposit yet found in the mine.

Occidental.—The lower tunnel is being driven with energy, but harder rock being encountered, not so fast as could be wished.

Hope.—The daily yield is 30 to 35 tons of $20 ore, keeping both mills running. A fine body of ore is developed at the lowest level.

Overman.—Daily yield, 130 tons from the 226 and 500-foot levels. No prospecting at the lower levels.

Bowers.—Work was started up in the old Bowers mine, during the past week, under a contract.

Kentuck.—Yielding 35 tons of ore per day.

WHITE PINE.

Items.—*News*: Bullion shipments for the week ending May 23d amounts to $45,720.70, of which $29,571.06 went to San Francisco and $16,149.84 to New York. Of this amount, the Aurora South shipped $13,741.25 and the Original Hidden Treasure $6,092.64. The shipment of the South Aurora mine and Stanford mill for the last 35 days foots up $77,821.18....Four Aces is rapidly developing into a first-class mine, the ore being singularly free and abundant. ....Bowie & Brown shows a continuous body of milling ore on each side of the 50-foot tunnel....Original Hidden Treasure shipped $6,092.64 in bullion last week.... Coin, near the north end of the Base Metal Range, is showing a body of very rich ore in the left face of a 15-foot incline from the open cut—average assays showing $1,127.86 to the ton....Work is to be recommenced on the Phœnix, closed since last fall....Erie (base metal) is down 122 feet in a 7-foot vein of solid ore assaying $1,200 to the ton in silver. A fine road has been built to the Shermantown grade. ....Shipped, 23d, base bullion, 666 bars, weighing 60,250 pounds.

Outside Districts.—Many are prosperous. Silver Park runs 20 stamps. Ely runs 5 only, but in a few weeks will add 20. The machinery of a mill for Shoshone is now on the road. Patterson is attracting more attention. Robinson is building smelting works.. Cooper is opening splendidly, and the Mollie Rutter mine is shipping ore to Silver Park. Clifton is attracting a great deal of attention, and rich discoveries of gold and silver have been made. Kern is rapidly filling up with the right kind of men. Pinto has been shipping large quantities of high-grade base ore. Eureka is prosperous, and is shipping large quantities of base bullion. The mill of the Social and Steptoe Co. has been temporarily closed while the change is being made from wet to dry crushing.

Bald Mountain.—A correspondent says: "The variety of ores, the unlimited supply of wood for reduction purposes, and its never failing supply of water—a rare occurrence in Nevada—will, upon the completion of the proposed railroad from Elko to White Pine, render it second to no mining district in the State."

Idaho.

Loon Creek.—*Avalanche*, May 21st: A friend at Oro Grande writes that the water had been so high as to stop all work, but the miners thought they could resume operations Monday. The high water had done no damage.

Snake River Mines.—Work has been suspended owing to the high water, which will last two months yet. There have been some very rich spots discovered, but few claims yet struck are regarded as of much importance.

The Ida Elmore, Golden Chariot and Corduroy mines continue to yield rich quartz in abundance.

Summit Flat.—The *World* says Mr. Clarkson has 150 tons ore on the dump from the Mammoth lode. Mr. Goodwin's mill started up a few days ago on rock from the King ledge. The ore looks well in both lodes.

Centerville.—The mill of the Gold Hill Co., Granite creek, cleaned up after a ten days' run, on what was considered refuse quartz, $4,200.

Mexico.

Sinaloa.—Copala cor. of *Alta*, May 11th: The Sombrero mine is paying $4,000 a week, under the management of one of the chief owners. The Cinoseros mine, once famous, has been taken hold of by a San Franciscan of means and gives evidence of being restored. Captain S. S. Davis has a well organized band of Mexican miners at work, at prices for labor less than a third of the rates paid in the silver mines of Nevada, and the ore is of high grade. The Alicran mine is likely to show results similar to Sombrero.

New Mexico.

Sale of the Maxwell Grant.—Santa Fé *Post*, May 21st: We learn that Lucien B. Maxwell, Esq., has effected a sale of his land grant to a company of English capitalists for the sum of six hundred and sixty thousand dollars.

The *Press and Telegraph* of May 21st says the new mines are in Grant county, New Mexico. The same gives a letter from Ralston, the town laid out at the mines, which confirms the accounts which have been published. For further news from these new mines, our readers may this week look under the head of Arizona.

Oregon.

Canyon City.—Dalles *Mountaineer*, May 24th: The miners of Grant county are doing unusually well this year, and already large amounts of gold dust have been shipped away.

San Francisco Mining Stock Market.

The mining share market exhibits no buoyancy, and prices of nearly every stock on the list have declined since our last issue. Nevertheless, the business of the Board has been very fair, the sales aggregating fully as much as for some weeks past, but it may be remarked that these transactions principally partake of a speculative nature, outsiders still continuing reticent with regard to investment. At the close, a very marked decline took place in some of the leading stocks, which induced holders to part with their shares rather freely.

Chollar-Potosi—has been moderately active at uniform figures, closing at a recession. During the week ending May 27th, 1,142 tons of ore were extracted, showing an average assay value of $50 50 to the ton. Since our last report, the Belvidere section has yielded a large amount of ore, and, with the exception of the tunnel level, the various faces look equally as well as they did the previous week. At the first station of the New Shaft the raise has been completed, and they will soon commence to drift west.

Gould & Curry—sold rather freely at a rapid decline, particularly at the close. For the week closing May 30th an ore-product of 403 tons is reported, the average assay-value being $44 20 per ton. During the same time the following work has been accomplished: fifteen feet have been added to cross-cut No. 1, on the 7th station—face in black porphyry; 23 feet have been made in cross-cut A—quartz, with small seams of clay; advanced 25 feet in the incline on the second station—rock and quartz; from the 14th floor, 100 feet below the lower adit, a drift was started west on the 23d of May, and in a week's time 42 feet were made, showing quartz and porphyry. In the El Dorado level, the cross-cut running west is yielding a considerable quantity of good ore, and in the south-east drift, middle adit level, sixteen feet have been made, the face showing quartz, clay, and porphyry. A drift was started west from the United States Tunnel, on the 23d of May, and driven 40 feet, encountering quartz and porphyry. They recently sent forward $10,713 in bullion.

Hale & Norcross—has been dealt in to a limited extent, realizing less than opening rates of the week. During the week ending May 28th, the various ore-producing localities yielded as follows: 175-level, 205 tons; 300-level, 148; 535-level, 219⅛; sixth station level, 105⅛; seventh station level, 770¼—total, 1,448¾ tons; previous week, 1,698⅛ tons. They have in the dumps, 5,830 tons. The various deposits of ore continue to yield largely, and, having their ore-houses full, they availed themselves of the opportunity to retimber the shaft the present week. On the 31st of May they sent forward $27,166 in bullion.

Kentuck—continues to decline. During the week closing May 27th, 190 tons of ore were extracted, yielding an estimated value of $3,146 53 in bullion, equal to $16 56 ℔ ton.——**Crown Point** also declined. For the week closing May 27th, 274¾ tons were raised, valued at $6,749 65, or $20 92. Annual meeting, Monday, June 6th.——**Imperial** declined to a considerable extent. A letter dated May 31st says that no change has taken place in the 1,200 drift, and that they still continue in porphyry. The winze had attained a depth of 52 feet, mostly in clay, showing that the wall is turning to the west.——**Segregated Belcher** sent forward $5,072 48 in bullion on the 1st, and from $4,000 to $5,000 was shipped on the 2d.

Belcher—sold to a larger extent than during the previous week, at the recent sympathetic decline. On the 30th of May, they sent 484 tons of ore to the Rhode Island Mill, and forwarded $7,571 73 in bullion to the office in this city. It is said that the ore cut 55 feet above the 262 level continues to yield well.

Sierra Nevada—has been rather active at uniform figures. The ore product for the month of May is given at 1,800 tons from the gravel deposits, and 20 tons from the ledge.——**Ophir** changed hands freely at a material decline. On May 31st, they cut the west wall at shaft No. 1, without finding anything at all encouraging. The southwest drifts show no change of importance. At shaft No. 2 work has been discontinued, and at shaft No. 3 work is going on as usual.——**Eureka** (Cal.) announces the usual monthly dividend of $7 50 per share, and an extra dividend of like amount, aggregating $60,000, payable on and after the 7th inst.—*Commercial Herald.*

* * *

The beet sugar-mill now in course of erection near San Lorenzo, Alameda County, has a capital stock of $225,000. The cost of the mill will be about $75,000, and it can use fifty tons of beets per day. If these beet-sugar experiments succeed, they will do more to bring California up than any other one thing we can think of.—*Bee.*

* * *

France consumes 910,000 tons of beef; England, 1,560,000 tons, and the United States 2,000,000 tons of beef each year. If quantity decides the point, Uncle Sam can justly brag of being able to beat Johnny Bull at his own table, and claim the prize for being the biggest beef-eater. He, one time, came near eating up the Bull himself.

San Francisco Prices of Copper Ores.

San Francisco, June 2, 1870.

W. T. Atwood states the following as approximate price at which copper ores can now be sold in this city. There is no sale for ores which assay less than 10 per cent.:

	Per ton.		Per ton
12 per cent. ore	$24 00	18 per cent. ore	$41 40
13 " "	26 85	19 " "	44 65
14 " "	29 40	20 " "	48 00
15 " "	32 25	25 " "	82 50
18 " "	35 20	30 " "	75 00
17 " "	38 25		

Ores assaying above 30 per cent., $2.50 per unit. Bars at the rate of 13c. per lb. for pure copper.

* * *

Nova Scotia Gold.—The returns from the gold fields of Nova Scotia for 1869 show a small falling off in the yield of gold as compared with the previous year. The declared returns of the past eight years show a yield of 157,682 ounces. The average number of miners daily employed was 713; the amount of quartz crushed was 4,092,679 cwt.; the average per ton (of 2,240 lbs.) was 15 dwt. 10 gr.; and the annual earnings per man, $553.90. Last year 17,868 oz. 10 dwt. 19 gr. of gold were produced; 708,486 cwt. of quartz were crushed; the average per ton was 11 dwt. 5 gr; the number of miners daily at work, 676; and the annual earnings per man were $528.64 The gross yield for the past ten years is estimated at 180,000 oz., worth, in round numbers, $3,600,000.

* * *

Personal.—Hon. Charles L. Flint, who has most ably filled the office of Secretary of the Massachusetts Board of Agriculture for the last eighteen years, and Mr. Geo. E. Noyes, publisher of the Massachusetts *Ploughman*, one of our most valued agricultural exchanges, are now in this State, on a tour of observation. We had the pleasure of a call from them a few days since. They are now on a visit to the Yosemite and Big Trees.

Our Wool Interest.—Sheep-raising has been carried on to a very considerable extent in California, and the business seems now to attract a large share of the attention of capitalists. The results of the present year's work are just beginning to be ascertained, and thus far the accounts are very encouraging. From a late Sacramento dispatch, we learn that Thomas McConnell, a citizen of Sacramento county, has just finished the clipping of 3,500 head of fine Spanish Merino sheep. The clip weighed 25,030 pounds, averaging 7¾ pounds to the fleece—in addition his flock dropped 2,500 lambs. This is certainly a very fair showing, and conclusively proves that the business of sheep-raising is one which yields a very heavy profit on the sum invested. A late dispatch from Los Angeles says that the receipts of wool from the interior are immense. Over one hundred thousand dollars' worth passed through that city during one day of the present week. If these are not encouraging facts, then we are very much mistaken.—*Oakland Transcript.*

Arizona letters say the reputed gold discoveries at Tubac are unfounded.

Farming and Gardening.

Communications for this department are solicited from all parts of the Pacific States and Territories.

Farming in Mining Districts.

It is commonly supposed that gold-producing countries are poor and barren, and the outcropping bare rocks which usually appear in the vicinity of shallow alluviums are the only accompaniement of rich placers, and that the poverty of the soil is compensated for by the gold which sparkles in the sands of the streams. The mines of Victoria have shown the unsoundness of this long-established theory. Side by side with the gold miner we see the farmer busily plowing rich chocolate soils which yield heavy and good crops. In the midst of a field of yellow corn there rise the engine house and chimney which mark the spot where the miner has sunk a shaft for a deep lead; and on the slopes, falling towards the sites of puddling machines, and sluicing operations, we behold rich vineyards and well-stocked orchards. Near even some quartz workings there are gardens. There are fruit trees which yield more to the cultivator than he could hope to gain in the same way in any other country; and scarcely a patch of land is too poor for a Chinese gardener. If he has water and a good market he will make the bare rocks grow "green."

We can see the miner, in the intervals of his labor, cultivating a garden which surrounds a cottage better in appearance and more comfortable in its arrangement than many which in England are inhabited by those who do not depend on the labor of their hands for their support. And under no circumstance—not even where thousands congregate on a new gold field—are we justified in saying that the miners of Victoria are not immensely superior to the class that are employed in the mines of Europe.—*R. Brough Smythe.*

The above may be largely applied to the mines of California; but not to that extent which the opportunities here warrant. The feasibility of adapting our foot-hills and many of our higher mountain valleys and table lands to agricultural purposes, is just now exciting much discussion, especially among the mountain journals. The experiments which have already been made show that we have hundreds of thousands of acres among the mines which might thus be employed to good and profitable advantage. There are hundreds of places in Nevada, Placer, El Dorado and other mining counties, where many patches of ground, varying from one to ten or more acres, on which may be found fruit of every kind, and in some places the cereals in great abundance and altogether superior in quality to that produced in the valleys. The net proceeds of some of these ranches and gardens are very large—much larger than can be realized from the same extent of ground in the great agricultural valleys of the State. As an instance of the profits of mountain fruit-growing we may state that Mr. J. M. Reese, of Auburn, Placer county, last year realized from seven acres of ground, planted with peaches, apples, pears, etc., a net profit of $1,850 over and above cultivation, packing, marketing, etc. This is but one example among scores of similar ones which might be mentioned.

Experience has proven that but little artificial irrigation is needed—none, in fact, is wanted for trees and vines after they have become well rooted. Plowing and frequent stirring the ground is better than irrigation, and produces a much better quality of fruit.

The Auburn *Stars and Stripes* gives the following figures of the average yield, last year, of grape vines on Mr. Reese's ranch, cultivated *without irrigation*, and upon ground which many would think too poor to yield even a crop of common peas: Common Los Angeles grape, per vine, 30 pounds; white cerian, 60; muscat, 60; malaga, 60; black vinsindall, 60. These figures are from accurate weighing; the vines being five years old. Eight hundred of such vines may be planted on one acre. Estimating the yield at only one cent a pound, and 30 pounds to the vine, we should have $240 per acre. Grapes will almost everywhere command that price for wine, and would do so, if the present crop in this State was increased twenty fold. With such exhibits need anyone despair of the future of our mining counties?

Let the miners acquire titles to the lands on which their mines are located, and to the surrounding acres, a portion of which, in almost every locality, may be made productive, if it is not already so. A fruit and vegetable garden connected with a mine will always improve it; and the labor of preparing it may generally be done at odd hours, which would otherwise be spent in idleness. Such surroundings indicate thrift, permanence and value. We want to see, all over California, the gold miner, side by side with the farmer, working in unison, harmony, and, as far as it may be, in partnership. Such improvements will give permanence to our mining population and improve it, both socially and in purse. If the miner has the will and the energy he may make even the bare rocks grow green—and make it pay, too.

A New Variety of Wheat(?).—Mr. D. W. Ramsdell, of Norway oats notoriety, claims to have discovered a new variety of wheat, which he offers at the moderate price of $1 per pint! The wheat is no doubt a very good article; but probably no better than any farmer can produce by a careful selection and cultivation of seed for a series of years. Very few farmers seem to appreciate the advantages derivable from such care in the production of seed wheat.

Cultivation of the Gladiolus.

We give herewith an illustrative plate of seedling *gladiolus*, prepared by the zincotype process of engraving—or etching by the use of acids—one or two previous specimens of which have already been given in the Scientific Press. We also append a short history of the plant and some few directions for its culture in this climate.

Among bulbous flowering platns there are but few which deserve to rank higher than the *Gladiolus*. This elegant flower was first introduced into Europe by the early Dutch florists from the Cape of Good Hope. The earliest varieties were the *Gladiolus Byzantinus* and the *Gladiolus Communis*. The blooms of these varieties were of some one color, and confined to purple, red or white. In later years other varieties were introduced, many-colored, and of different, more various and brighter hues. Among the latest of these subsequent importations were the *G. Gandavensis*, orange, scarlet and yellow; *G. Floribundas*, shaded rose, pink or white; *G. Ramosus*, a beautiful rose color, marked with white and carmine. From these have been produced, by the florists of Europe, the great number of varieties of this beautiful plant with which the gardens of this country and Europe are now ornamented. So rapidly have the different varieties been produced that Henderson has truthfully said "they are now almost numberless, varying in every shade of their beautiful markings, which range through all degrees of scarlet, crimson, purple, carmine, rose, yellow and violet, down to white."

SEEDLING GLADIOLUS.

New varieties are obtained from seed, the *modus operandi* of which for this country may be given as follows: The seed should be sown in a light, peaty, warm soil, lightly covered and shaded from the hot sun. When the young plants are two or three inches high, they should be separated and allowed to make the fullest possible growth. The bulbs should be allowed to remain in the ground through the first winter. They will bloom the second year in California. It is perhaps better to start the plants in pots, in the green-houses.

The gladiolus is of easy culture. It requires a loose warm soil made rich by good and thoroughly decomposed manure. In setting, the ground should be thoroughly stirred to the depth of fifteen or twenty inches. Any good garden soil will be suitable; but, if particularly stiff, add sand. The plants should be set at least two feet apart. They appear to best advantage in rows. In planting the bulbs they should be covered about three inches, and provided with suitable stakes, to sustain the plant. The stakes should be painted a light green, as that color will more readily harmonize with the stalks of the plant.

Large bulbs will usually give the best flowers, though those not more than three-quarters of an inch in diameter will furnish some, though inferior blooms. They will require little cultivation, with the exception of keeping the soil loose and free from weeds, in doing which care is needed that the leaves are not cut or mutilated, as the growth of the bulb is thereby injured. Leaves should not be removed for appearance sake, unless they have turned brown. If the flowers are not desired for use, the bulb will be benefited by their removal as early as they begin to fade, as the forming and ripening of the seed is done at the expense, to some extent, of the bulb. Gladiolus increase rapidly by offshoots or division of bulbs, the largest ones usually furnishing the greatest number.

How to Make Cuttings Grow.

In alluding to the manner of propagating cuttings, the *New England Farmer* says that it has been ascertained that a cutting will develop roots much sooner in *moist sand* than in *rich soil*. But the sand cannot maintain its growth for any length of time. To prepare pots for raising cuttings they should be filled nearly to the brim with rich garden loam—dark and porous, not clayey and soggy; then pour in one inch in depth of scouring sand—sea sand will do as well as the yellow sand. Wet this thoroughly, and place the cuttings, from which all but the three or four upper leaves have been removed, close to the side of the pot; the contact of the ware against the stem of the cutting promotes its growth. Press the wet sand *firmly* around the tiny stem. A great deal of your chance for success in raising slips or cuttings depends upon this. Plant as many cuttings as the pot will hold, from six to a dozen, according to the size of your pot; when they are firmly set in the sand, two or three can be inserted in the middle of the pot. Set them away in a dark, warm place for twenty-four or thirty-six hours. Thus, cuttings will grow quickly in a hot bed, because the temperature is not dry. Their growth depends a great deal upon light, heat and moisture. If a bud is close at the base of a cutting it will strike root more easily—is not so apt to decay. The roots shoot from a bud, and the lower down it is the surer your success. When the leaves drop, the plant is commencing to grow; if they wither on the stem, it has begun to decay. By following these directions no one can fail to grow all kinds of house plants. Roses and all the rarest flowers of the green houses are propagated in this manner.

Silk Bounties Paid.—Warrants have been issued under the Act of March, 1868, for the encouragement of silk culture, in accordance with the findings of the State Board of Agriculture, viz.: H. G. Ballou, Yolo, $300; E. M. Weston, Yolo, $1,875; S. J. Scuffregan, Leon Gambert, Los Angeles, $250 each; A. Packard, Santa Clara, $450; A. Isoard and A. Miller, Nevada, $250 each. These awards were made for the culture of cocoons and mulberry plantations.

The "Hog Cholera."

The Commissio[illegible] Agriculture, in his report for March and April, alludes, at considerable length, to the increasing mortality among swine, which is becoming quite alarming throughout the Atlantic States. The Commissioner thinks there must be something radically wrong in the management of this animal, or we should not witness such a wholesale mortality, for which the butcher has no responsibility, especially among young pigs. The loss is largest in the West, notwithstanding the healthful range which is so generally allowed the animal in that portion of the country. The close quarters, in which Eastern pigs are kept, would thus seem to be advantageous.

The disease is usually termed "hog cholera," although it [illegible] lly epizootic—proceeding from various species of *parasites*, which infest the living tissues—thus rendering this, at best, unhealthy and unwholesome animal still more unfit for human food. It is already well known that some of these parasites are capable of being transferred to the human system, where they are sure to become as fatal as in their original home.

In some localities the loss is reported at from 20 to 30 per cent. of the entire number of swine. The evil has become so great as to produce much discouragement among the pork raisers in some of the worst infected districts.

The first symptoms of the disease are an appearance of stupidness; then the limbs become stiff, appetite fails, and vomiting occurs as the final stage. They generally die in a few days after the disease has fairly set in. All ages, sizes and conditions appear to be subject to the disease.

The trouble has generally been thought to proceed, in a great measure, from the large quantities of corn upon which hogs are fed, which is considered too concentrated for the continuous diet of this or any other animal; hence those who feed potatoes and other roots, and sloppy food from the kitchen, etc., are less troubled.

Mr. James Harkness, of St. Louis, Missouri, however, writes to the Department a letter, in which he attributes the chief cause of the trouble in question to a beautiful butterfly which has lately become very plentiful, and is seen especially in every clover field. This insect lays its eggs in the clover bloom, which is eaten by the hogs; the eggs subsequently developing into worms, much as the "nits" of the bot-fly are developed in the horse.

Mr. H. suggests, as a preventive, that hogs should be kept away from clover, and fed more upon timothy, herd, orchard and other grasses instead.

A remedy has been found practicable, to a great extent, in the free use of coal ashes, charcoal, salt, sulphur, soap, coal oil, sulphate of iron, etc. Soap suds, tobacco, assafœtida, and nearly all the poisons of the apothecaries' shop—even to strychnine—have been used. It is said that sulphate of iron administered in the proportion of a tablespoonful for a hog of 150 to 200 pounds, once a week, mixed with the food in the slop barrel, is an unfailing cure, and will kill every worm before it leaves the intestines, as sure as prussic acid will kill red-blooded animals.

The remedies suggested are good for all domestic animals troubled in this way, as they are very obnoxious to worms of any kind, in or out of the stomach.

We believe the disease in question has not yet made its appearance, to any considerable extent—if at all—upon the Pacific coast. At least it has not yet been reported to the Department. Still it is well that our people should be advised of its progress at the East, and be prepared to guard against its appearance here. The only reference to California, in the Reports, in this connection, is the following: "The business of swine raising in California is in the hands of a few, and is followed as a distinct one. Those in it keep from 200 to 1,500 or more, herding them in the foot-hills during the rainy season, where roots and mast abound. After grain is cut and threshed in July and August on the plains, the owners of hogs buy the fields for the season, and turn their hogs into them, where they feed until fall, when the fat ones are sold for pork in the best market, usually San Francisco. From the scarcity of mast and roots, the increase in herds was less the past year than formerly. The use of the header in harvesting, in place of the reaper, leaves less grain in the field than former years, consequently the hogs made less pork last fall than other years. The falling off in the increase of stock and in the weight of pork in this county may be placed at two-tenths.

What I Know of Farming—No. 20.

Bones—Phosphates—Guano.

I hate to check improvements or chill the glow of faith; yet I do so keenly apprehend that many of our people, especially among the Southern cotton growers, are squandering money on commercial fertilizers, that I am bound to utter my note of warning, even though it should pass wholly unheeded. Let me make my position as clear as I can.

I live in a section which has been cultivated for more than two centuries, while its proximity to a great city has tempted to crop it incessantly, exhaustively. Wheat, while its original surface soil of six to twelve inches of vegetable mold (mainly composed of decayed forest leaves) remained; then corn and oats; at length, milk, beef and apples—have exhausted the hill-sides and gentler slopes of Westchester county, except where they have been kept in heart by judicious culture and liberal fertilizing; and, even here, that subtle element phosphorus, which enters minutely but necessarily into the composition of every animal and nearly every vegetable structure, has been gradually drawn away in grain, in milk, in bones, and not restored to the soil by the application of ordinary manures.

I am convinced that a field may be so manured as to grow three tons of hay per acre, yet so destitute of phosphorus that a sound, healthy animal cannot be grown therefrom. For two centuries, the tillers of Westchester county knew nothing of chemistry or phosphorus, and allowed the unvalued bones of their animals to be exported to fatten British meadows without an effort to retain them. Hence, it has become absolutely essential that we buy and apply phosphates, even though the price be high; for our land can no longer do without them. Wherever a steer or heifer can occasionally be caught knawing or mumbling over an old bone, there phosphates are indespensable, no matter at what cost. Better pay $100 per ton for a dressing of one hundred pounds of bone per acre than try to do without.

But no lands recently brought into cultivation—no lands where the bones of animals fed thereon have been allowed, for unnumbered years past, to mingle with the soil—can be equally hungry for phosphates; and I doubt that any cotton field in the South will ever return an outlay of even $50 per ton for any phosphatic fertilizers whatever. That *any* preparation of bone, or whereof bone is a principal element, will increase the succeeding crops, is undoubted; but that it will ever return its cost and a decent margin of profit, is yet to be demonstrated to my satisfaction.

No doubt, there are special cases in which the application even of Peruvian guano at $90 per ton is advisable. A compost of muck, lime, etc., equally efficient, might be far cheaper; but months would be required to prepare and perfect it, and meantime the farmer would lose his crop, or fail to make one. If a ton of guano, or of some expensive phosphate, will give him six or eight acres of clover where he would otherwise have little or none, and he needs that clover to feed his team wherewith he is breaking up and fitting his farm to grow a crop next year, he may wisely make the purchase and application, even though he may be able to compost for next year's use twice the value of fertilizers for the precise cost of this. But I am so thorough in my devotion to "home industry," that I hold him an unskillful farmer who cannot, nine times in ten, make, mainly from materials to be found on or near his farm, a pile of compost for $100 that will add more to the enduring fertility of his farm than anything he can bring from a distance at a cost of $150.

Understand that this is a general rule, and subject, like all general rules, to exceptions. Gypsum, I think every farmer should buy; lime also, if his soil needs it; phosphates in some shape, if past ignorance or folly has allowed that soil to be despoiled of them; wood ashes, if any one can be found so brainless as to sell them; marl, of course, where it is found within ten miles; guano very rarely, and mainly when something is needed to make a crop before coarser and colder fertilizers can be brought into a condition of fitness for use; but the general rule I insist on is this: A good farmer will, in the course of twenty or thirty years, make at least $10 worth of fertilizers for every dollar's worth he buys from any dealer, unless it be the sweepings or other excretions of some not distant city.

I have used guano frequently, and, though it has generally made its mark, I never yet felt sure that it returned me a profit over its cost. Phosphates have done better, especially where applied to corn in the hill, either at the time of planting or later; yet my strong impression is that flour or bone, applied broadcast and freely, especially when wheat or oats are sown on a field that is to be laid down to grass, pays better and more surely than anything else I order from the city, gypsum, and possibly oyster-shell lime, excepted.

My experience can be no safe guide for others, since it is not proved that the anterior condition and needs of their soils are precisely like those of mine. I apprehend that guano has not had a fair trial on my place—that carelessness in pulverizing or in application has caused it to "waste its sweetness in the desert air," or that a drouth following its application has prevented the due development of its virtues. And still my impression that guano is the *brandy* of vegetation, supplying to plants stimulus rather than nutrition, is so clear and strong that it may not easily be effaced. It seems to be plainly absurd to send ten thousand miles for this stimulant, when this or any other great city annually poisons its own atmosphere and the adjacent waters with excretions which are of very similar character and value, and which science and capital might combine to utilize at less than half the cost of like elements in the form of guano.

My object in this paper is to incite experiment and careful observation. No farmer should absolutely trust aught but his own senses. A Rhode Islander once assured me that he applied to four acres of thin, slaty gravel one hundred pounds per acre of nitrate of soda which cost him $4 per hundred, and obtained therefrom four additional tons of good hay, worth $15 per ton; net profit (after allowing for the cost of making the hay), say $30. He might not be so fortunate on a second trial, and there may not be another four acres of the earth's surface where nitrate of soda would do so well; but, should I ever have a fair opportunity, I mean to see what a little of that nitrate will do for *me*. And I hope farmers may more and more be induced to conform in practice to the apostolic precept, "Prove all things: Hold fast that which is good." No one's success or failure in a particular instance should be conclusive with others, because infinite diversity of antecedents and attendant circumstances; but if every thrifty farmer would give to each of the commercial fertilizers—lime, gypsum, guano, raw bone, phosphates, ashes, salt, marl, etc.—such a careful trial as he might, observing closely and recording carefully the results, we should soon have a mass of facts and results, wherefrom deductions might be drawn of signal practical value to the present and to future generations.—*Horace Greeley.*

Importation of Flaxseed.—On the 26th of March, the bark Bell Hill sailed from Valparaiso for San Francisco with a cargo of linseed for the mill on King street in San Francisco. Another vessel was soon to follow with a similar cargo. It is well known that flax is easily raised in this State, and no argument is required to prove that a large number of persons could be profitably engaged in the production of crops of this character. The consumption of linseed oil on this coast is already extensive, and it must steadily increase. A little more enterprise on the part of our farmers would take them out of the beaten path, and lead to the discovery of many branches of remunerative production, to meet deficiencies now supplied from remote quarters of the globe.

A recent frost destroyed the fruit and foliage of about 7,000 of the 10,000 grape vines in the vineyard on the old Gwin rancho, near Snelling, Merced county.

The weather is so warm and dry in England that apprehensions are felt for the safety of the crops.

A Model Fruit Farm.

[Concluded from last week.]

The several acres of raspberries in Mr. Wilcox's fruit garden comprise many varieties, several black caps among the rest; but the *Red Antwerp*, *Falstaff* and *Knevet's Giant* occupy the larger space. Mr. W. gives the well-proved sorts and the approved methods of culture preference over doubtful ones generally. While profit is the first object, the results of a various trial will not be disregarded. He has the native *Yosemite*, but thinks little of it.

The greater part of his eleven acres of strawberries have been planted this season. Although he has some forty different varieties, he has, in general culture, but *one* sort, the well-known and reliable *Longworth's Prolific*. This is an American fruit, sub-acid with a sprightly flavor, and more nearly resembles the wild strawberry of New England than any I have tasted. It is more generally cultivated, and stands higher in the estimation of culturists here in Santa Clara county than any other kind. The berry is large, short, rough and uneven shaped,—the common sort in the San Francisco markets. The plant is very vigorous, long lived, bears early and late, and shows an abundance of dark and spreading foliage.

The *Jocunda*, a large, long, fine-looking but insipid berry, has attracted much attention. It promised well, bearing abundantly one season, but has proven worthless, and almost ruined the persons who have ventured largely and persistently into its culture.

Russell's Prolific has a fine flavor, but does not fertilize perfectly, and is fruitless.

Wilson's Albany, a splendid fruit in some localities, is out of favor in this county.

The *Triomphe de Gand*, a large, conical, smooth, glossy fruit, not quite so early as the *Longworth Prolific*, is sweeter, and will stand transportation better. Mr. Pancoast, who has thirty-three acres of strawberries near Santa Clara, has averaged three cents per pound more for this than for the *Longworth Prolific*. The *Triomphe de Gand* is a long-lived plant,—moderate bearer, and very thrifty grower; but the leaves are smaller and lighter colored han *Longworth's*.

As a general rule, the fruit-growers in California decide quickly as to the merits of varieties, and discard everything but the best approved. As a general thing, this is right; but it would be well to retain, as a standing test, a few sorts other than the favorites.

Unless a thing has real merit, this State is a poor place to undertake a "sell," such as is common in the Eastern nurseries.

Mr. Wilcox has a number of the *Zante Currant* grape, several of which will fruit this season. This grape will be a sure success in California, and is worthy of general attention. In the south of Europe it is grown in ditches dug in level terraces around the hill-sides. The ditches are kept full of water during the winter and allowed to dry out in the spring and summer. I am very doubtful as to the necessity of such treatment there, or of the policy of such here. We Americans are breaking through all old fixed stereotyped rules, and are making money by it. An experimental and practical knowledge of simple principles is better than all scholastic training.

Mr. W. is also accumulating a variety of nut trees, shrubs, ornamental trees and plants. An artesian well, over 300 feet deep, supplies an abundance of pure water for irrigating his grounds. It flows with sufficient force to throw a stream through hose twenty-five feet high. This well, though a wonder in itself, is no uncommon thing in this valley. Hundreds of such are flowing and sparkling amidst groves and gardens and green fields, every one teaching a beautiful lesson of temperance in refreshing streams. An unsightly slough that runs through the prettiest part of Mr. W's grounds, will be dug into shape for a fine fish pond, to be supplied by the artesian well and lined with a variety of shadowing trees.

In many respects, Mr. Wilcox's place makes a fine showing for two years of time of what California soil and climate can do, and something of what a working man on the right track can achieve, when determined to succeed. As our friend can use the pen as well as the spade, I will not anticipate more, but the readers of the Scientific Press may expect something from him occasionally, as to the results of his methods, progress, experiments, etc.

Notices to Correspondents.

Raising Horses.—Will our Harrison street correspondent, who sends a communication on "Raising Horses," call at our office, 414 Clay street? We should like an interview with him.

Blasting by Electricity.—We will endeavor to furnish our correspondent, who makes inquiry for a suitable battery for employment in blasting by electricity, with the information he seeks in our next issue.

J. R., Santa Cruz—We will endeavor to report on your query with regard to the grape-vine destroying insect in our next issue.

Arrival of the Boston Party.

The Boston party arrived in this city on Tuesday night between twelve and one o'clock. The train of nine cars was (by special permission) brought to the very doors of the Grand Hotel. When it arrived there was a large crowd on Market street, notwithstanding the lateness of the hour. The Grand Hotel was lighted up and Bancroft's building was brilliantly illuminated. As the cars came down Market street, the crowd gave rousing cheers, and here and there a blue light was set off. A delegation from the Chamber of Commerce of this city had met the party at Stockton, and we hope the Bostonians were pleased with their welcome to this city.

We join in offering our congratulations and good wishes to the excursionists who come as representatives of the fair city on the Atlantic coast. We are always heartily glad to see deputations from other places, and believe that by thus personally coming to our shores, they are doing much to further good feeling among the various parts of our wide country. We need a better personal acquaintance with one another, which does much towards establishing friendly relations and uniting us more firmly in the bonds of union; and for this reason especially, we utter a cordial welcome to our Eastern brethren.

A Portable Assaying Machine.

An assaying apparatus, which could be carried about easily and be of practical use in the field, has long been a *desideratum.* The blow-pipe, with its delicate tools, is suitable merely for the laboratory, and the common assaying furnace is too cumbrous to be of any general application. We know of no device, hitherto, which has combined the necessary qualities of compactness, durability and requisite accuracy.

Last September, however, Mr. J. S. Phillips, a mining engineer of San Francisco, who has had long experience in assaying, both in the laboratory and in the field, patented an apparatus which, he claims, satisfies all these demands, and can be readily used by the prospector, who needs but a few hours' instruction to be able to assay his rock, wherever he may find it, at a cost of but a few cents.

The illustrations show the machine in three positions. In Fig. 1, it is arranged for roasting, drying and fusion; in Fig. 3, for the general purposes of the analyst and assayer; and in Fig. 2, packed for traveling in a five or six-inch box. Into this small space are condensed all the tools and fluxes, in short, everything necessary for a complete assay, as well as the articles requisite for shaping the charcoal supports, the cupels, etc., etc.

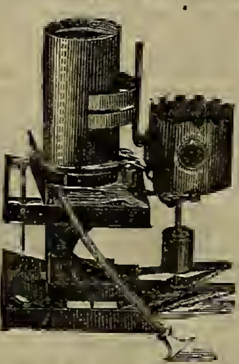

Fig. 1.

One great object of this invention was to put into the hands of the uneducated prospector a device which would be automatically so complete that the operator could obtain proper results with the need only of a few hours' instruction and the application of a little care. Hence it is made as simple as possible; the weights and similar articles are of a size to be readily handled by fingers used to the pick, and are marked so as to prevent the possibility of mistake; and the results of the assay are marked down before the eye, requiring only the ability to read on the part of the assayer. We have not room to describe all the various details. We give, however, the general method of making an assay.

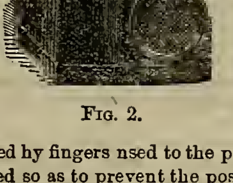

Fig. 2.

The pulverized sample to be assayed, being well mixed, is ground to a fine powder in the mortar, and then ten grains are weighed in the pan shown at the back of the device in Fig. 1. After being fluxed, it is poured into a previously prepared paper cartridge and shaken to mix it. The cartridge is folded and put in a molded charcoal support, which, again, is placed in a metal cup, shown in Fig. 3, in front of the furnace, which has a long stem, and is so arranged that it can be readily adjusted in any position required. Next, a piece of charcoal, or a small furnace containing several, is suspended in the metallic bands or fingers above the assay, and the flames of four olive oil lamps are blown on the sample by means of an arrangement which requires only an *occasional* blast from the lungs. This smelting operation lasts from ten to fifteen minutes, during which time the operator need only to blow once in a while and to give a general attention to the process, while at the same time he can converse and is otherwise at liberty to do what he may find convenient. By handling the non-conducting cork on the cup-stem and by means of spring levers, the cup can be altered in its position or removed when necessary. The lead button obtained is cleaned and cupelled in a similar manner on bone-ash supports.

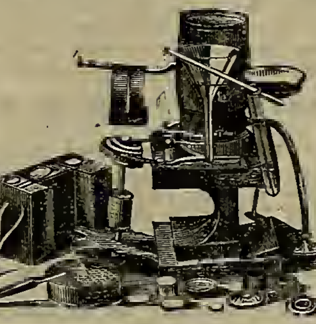

Fig. 3.

The refined bead is weighed and its value found in a very simple manner. In the pan suspended at one end of a lever is placed one of ten numbered weights. In the other grooved arm the bead is placed, until it just balances the weight, which fact is shown by a mark properly placed. When thus balanced, the value is read on a paper placed beneath the lever arm, and either in dollars per ton, or in thousandths fine for gold and silver, or the percentage of base metal, the device for reading being very simple and easily understood.

The Committee on Premiums at the last Industrial Exhibition of the Mechanics' Institute awarded Mr. Phillips a first premium and gold medal, and report that "for convenience in use and accuracy in performance, we esteem this little machine as of the greatest utility to the mining prospector, and well calculated to relieve our mining interests of the uncertainty hitherto attending their development." A letter from a Superintendent at Galena, Battle Mountain district, reads: "I think a great deal of my machine and feel the need of it every day." We have seen assays made by Mr. Phillips with his machine in a very expeditious and satisfactory manner.

The above brief description will serve to show that the inventor has aimed to produce a practical article which should be at once sufficiently accurate and sufficiently simple for the prospector. He has two or three sizes, all of which, however, can be packed into a very small compass. The price is $100, which includes instruction, tools, calculating balance, weights, fluxes, etc., etc. Those who are interested or engaged in prospecting operations would do well to call themselves and personally examine the apparatus, which was patented in September, 1869, through the agency of the Scientific Press, and which may be seen at the office of the inventor, Mr. J. S. Phillips, 423 Washington street, San Francisco.

◆

Decoration Day was observed in many cities on this coast as well as at the East, on last Monday. The custom is a most beautiful and appropriate one when carried out in the proper spirit, and can be made to do much towards softening the feelings and healing the wounds caused in our late civil strife. By all means let us honor those who died in vindication of what they thought was right, and for the welfare of their native land.

◆

Balbach's patent wagon spring will be illustrated in our next.

Patents and Inventions.

A Full List of Patents Issued to Pacific Coast Inventors.

[From Official Reports to DEWEY & CO., U. S. and Foreign Patent Agents, and Publishers of the Scientific Press.]

For the Week Ending May 24th.

Street-Car Truck.—John Berry, San Francisco.

Dredging Machine.—William D. Robertson, San Francisco.

Amalgamator and Ore Concentrator.—Joseph Scott, San Francisco.

Water Wheel.—Henry W. Shipley, Portland, Oregon.

Gate Latch.—J. W. Still, San Francisco.

Note.—Copies of U. S. and Foreign Patents furnished by Dewey & Co., in the shortest time possible (by telegraph or otherwise), at the lowest rates. All patent business for Pacific coast inventors transacted with greater security and in much less time than by any other agency.

Notices of Recent Patents.

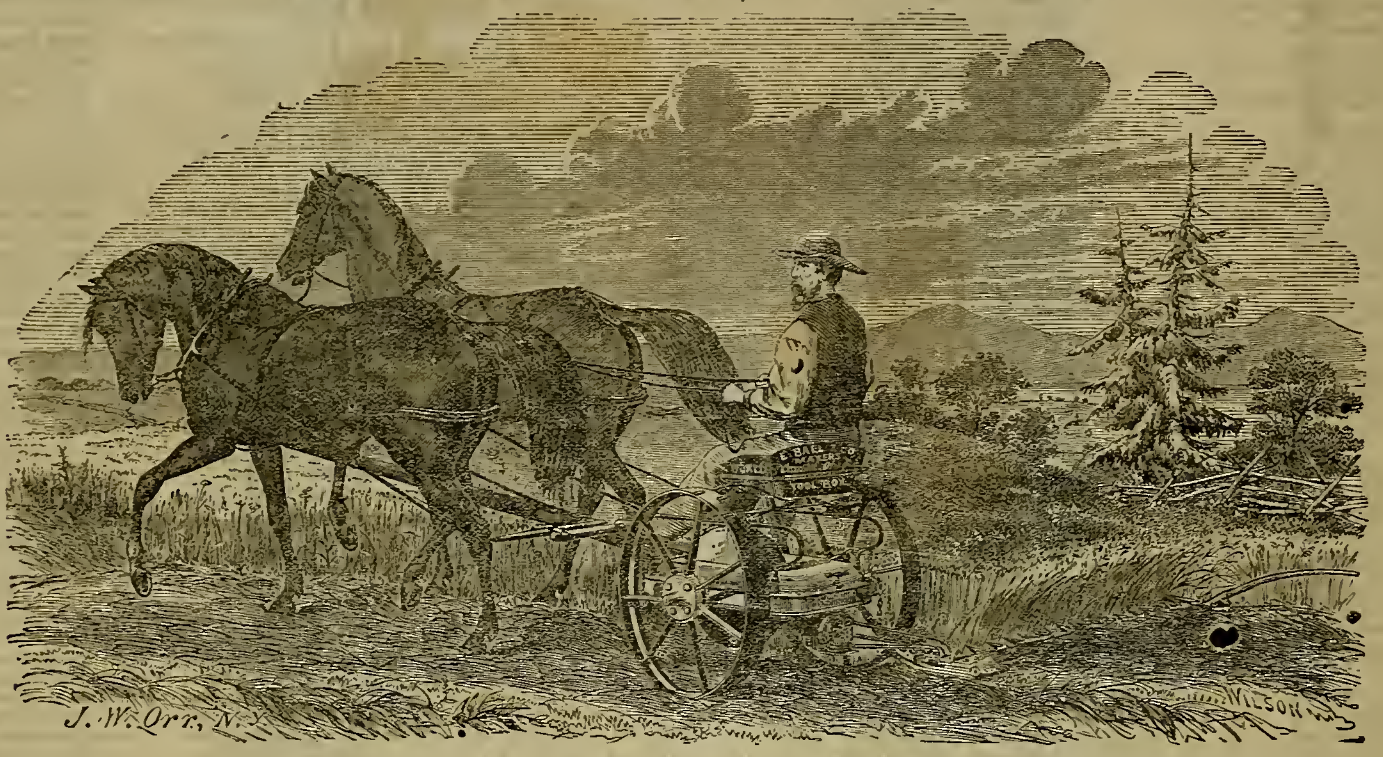
Among the patents recently obtained through Dewey & Co's Scientific Press American and Foreign Patent Agency, the following are worthy of mention:

Improvement in Breech-Loading Ordnance.—A. F. Potter, Oakland, California.—The nature of this invention consists in a certain combination and arrangement of cams and keys operated by a central pin, for securing the breech-core in a gun. The cannon is constructed in three general parts—the barrel, the breech-core and the key-pin—which, when put together, all concenter around a common longitudinal axis. The breech-core is, in its general outline, a hollow truncated cone of an external caliper measure and length to fit closely into the barrel of the gun at its breech. The key-pin is also a truncated cone which fits accurately into the inside of the breech-core. These two last named parts are firmly locked in place by means of a number of cams and keys, which play in appropriate grooves or channels, and which are easily actuated by means of a lever placed at the rear of the key-pin easily and quickly. Among the points of advantage claimed in these arms, the following may be mentioned: First, the construction; it unites firmness with simplicity in the fastenings of the several parts, which renders the gun easy of construction; is cheap, durable, easy of repair, and safe and certain in use. Second, in action it assures ease of handling, rapidity in loading, firing and cleaning, little liability to wear or burst, the minimum of escape of the gases of the charge in firing, the power of burning more powder in a shorter barrel, the ease with which the gun may be dismantled in defeat and rendered valueless to a captor though perfectly good to its owners so soon as retaken; and in small boats, launches, monitors and fortifications the absence of any need to run the gun in and out in loading and firing. In military tactics the soldier acts by "times and motions" in handling his arms. It would take too long to point out these in the tactics for different guns, some requiring more than others. Potter claims that with his gun, when used with his fixed ammunition, the times and motions required for pricking and springing are saved and fewer men are needed to handle the piece.

Stave-Jointing Machine.—J. W. Alesworth, Santa Cruz, California.—The object of this invention is to provide an improved gauge-box for giving to barrel-staves the proper bevel and taper to produce the swell in the center of the barrel, allowing the workmen to give each stave the same bevel and taper, and operating upon several at the same time with the greatest ease and accuracy. On a strong table is a box, on two sides of which are placed longitudinal strips of wood with their upper faces rounded or curved and metal-faced. These strips are removable, so that others with more or less curve may be substituted when necessary. The box is provided with a number of false bottoms, in order to give any desired width to the staves, and a beveled strip of wood is placed in the angle formed by the side and bottom and secured by cross-pieces, on which the staves are placed and where they are held by a screw. Below the table is a rack set in a block driven back and forward by a pinion operated by a hand-wheel. A lever attached to the block at its lower end, passes up through the table, where it is pivoted, and has on its upper end a piece of metal provided on one side with teeth, which serves as a clamp to prevent the staves from being moved while they are trimmed. A large number of staves can thus be easily beveled and tapered at one time.

The World Reaper and Mower.

This machine, which has been lately introduced on our coast, has been used for four years in the more easterly States, and has there obtained a most enviable reputation. It is built strongly and compactly of the best material, is of easy draft, and is claimed to be one of the most durable machines of the kind. It has the peculiarity that the working parts—except the wheel gear, the cutting knives and the rake—are protected from dust, water and other similar agencies which clog and disturb their action, by being inclosed in an iron case, which is placed beneath the driver's seat. This alone must add greatly to its effectiveness and durability.



E. BALL & CO'S WORLD REAPER AND MOWER.

Letters which have been received from farmers who have tried it, speak loudly in its favor. And it seems to be receiving a large share of the public patronage here, for of two car loads recently received, over one-half, we are told, have been already disposed of. It is certainly worth the trouble of an examination by those who need such machines. Our illustration gives a general view of the device, and further information as to the particular details may be obtained by applying to the general agents for the Pacific coast, Messrs. Linforth, Kellogg & Co., Nos. 3 and 5 Front street, San Francisco.

◆

Telegraphing and the Medical Profession.—We see it stated in an exchange that physicians are beginning to employ the telegraph in their practice. By having an apparatus in his office, connecting with the main lines, a doctor is enabled to consult with and prescribe for his patients elsewhere in much less time than is required for a personal call. It is stated that thus far the experiments in this direction have been attended with very satisfactory results. While the patient, in this way, loses the benefit of the personal presence of his physician, which is often of as much or even more influence than any medicine, on the other hand, she or he can have the advantage of communicating with him at any time.

◆

The Arizona and Sonora Mining Company propose, it is said, to send out a party of one hundred men, armed with picks and rifles, to work mines and repel Indians in Arizona. The expedition will leave this city about the 1st of August.

◆

Recent mineral discoveries are creating quite an excitement in India among miners.

The Steam Plow in Louisiana—The Advantages of Deep Tillage.

Some two or three years ago we mentioned the fact that Mr. E. Lawrence, an extensive sugar planter of Plaquemines Parish, La., had imported from England a 15-horse power Fowler steam plow. Since that time, two or three other plows, of the same make, have been imported for other sections. We now learn that Mr. L. was so much pleased with the work of his first importation that he has since imported a second machine of 20-horse power, designed more especially for certain portions of his plantation, which consist of a heavy, stiff clay soil, for the proper cultivation of which he found both the 15 horse steam plow and his ordinary plows inadequate. He now expresses himself highly pleased with the performances of these machines, both of which are kept constantly at work during the season for plowing and cultivation—each upon land suited to its capacity and power. Mr. L. evidently believes in deep plowing, and the comparative results which he obtains fully warrants such a belief and practice, on his grounds at least. When breaking up with the mold-board plows they ran to the depth of from 15 to 20 inches; when cultivating or subsoiling between the planted rows of cane they ran to the depth of from 20 to 24 inches! On lands thus plowed and cultivated he obtains *two and a half* hogsheads of dry sugar to the acre; while from lands every way as favorably conditioned, naturally, but cultivated in the ordinary manner by horse-power, and of course with shallow plowing, he obtains only *one and a half* hogsheads. On the latter, he says the stand of cane was equally as good, while *more* labor is bestowed on them than is expended on the steam-plowed lands.

He considers that the yield of steam-plowed and steam-cultivated lands is fully *fifty per cent.* greater than that of land cultivated with horse-power, while less than half the labor is expended upon the former than upon the latter! This testimony in favor of the use of steam in plowing and cultivating is the same which has long been given to the world by the farmers of England, where steam is now almost universally employed for such work.

It is singular that while the half-civilized people of Egypt are introducing the steam plow, by hundreds, upon the plains of the Nile, the go-ahead, progressive farmers of the Mississippi and Sacramento valleys are still doubtful of its economy. But prejudices against steam-cultivating machinery cannot much longer retard its general introduction upon this continent. The scarcity of, and rapidly increasing demand for labor, coupled with the abundant evidence of its superiority, which is now being placed before the public by the agricultural press of the country must soon work a revolution in this direction. In fact, it is the only thing which will supersede the necessity for the general introduction of Chinese labor upon American farms.

The estimation of the advantages derivable from the application of steam to the cultivation of the soil in the great valleys of the Atlantic States and of California, so admirably adapted for such culture, is beyond the power of human calculation, and will form the great feature in farming operations on this continent ten or fifteen years from this time.

In working out this change, the slow and half-way machinery of the English will not be accepted. American ingenuity will yet triumph in this as it already has done in every other department of agricultural machinery, and our farmers will soon have placed at their disposal a plow in every way calculated to meet the peculiar demands of such a machine. California will carry off the honors in this invention. The plow must be *revolutionized*, or made to revolve. The straight forward motion of the plow, as heretofore employed, is inapplicable to machinery. A *revolving* plow is needed, and time, in our opinion, will prove that either Standish of Martinez, or Locher of Oroville, have hit upon the principle which is to win in the construction of steam plows.

◆

A Pearl Mine is reported as having been struck in this city, on Washington street, one day this week. Two boys, on turning over the dirt in a gutter, are said to have found a large number of pearls and a nugget of gold, 900 fine, and already coined for use. As it is getting to be the custom to discover ores containing considerably over a hundred per cent. of the precious metal, we see no reason against opening up pearl mines in our city gutters.

◆

On the 19th of May, according to the Elko *Independent*, the first through mail left that place for Boise City, Idaho, on Hill Beachey's stage. The Winnemucca mail route has been abolished and switched on this route, which is via Cope District and Silver City.

The Patio Process.

Editors Press:—It has often been remarked that the usually accepted theory of the patio process is not quite satisfactory. Having certain suspicions, I made the following experiment: A little rich silver ore, of the Blind Springs district, Mono county, was ground, moistened, and mixed in a saucer with a quantity of calomel and salt, also a little mercury. It was kept moist, and thoroughly mixed daily with a wooden spatula. After two weeks it was washed, and yielded a pellet of fine silver amalgam, amounting to the greater part of what the ore had contained. I feel justified in assuming the extreme probability that the main agent in the patio process is not, as usually stated, the copper chlorides, but mercury subchloride ($\mathrm{Hg^2Cl}$). I admit that my experiment is not conclusive; but, in addition to the presumptive evidence it affords, many other reasons point to a similar view.

The quantity of magistral added to the pulp is not, usually, by any means the equivalent of the silver contained; and if it were, the "consumida" or chemical loss of mercury should be greater than it is. The length of time occupied is greater than would seem necessary were copper chlorides the chief agent. Moreover, in some places, ore is worked by the patio process without magistral, and without roasting, in which case I presume the ore to contain certain quantity of silver chloride by which calomel is produced. I, therefore, suggest that the office of the magistral is simply to initiate the formation of calomel, by which, with the aid probably of light, the reaction is carried on and perfected.

Metallic Soaps.

I have been hoping to hear more from our friend, Mr. E. Pique, on metallic soaps. It is an interesting subject, and I think some useful results might be obtained by investigation, though I have not time to follow it up myself.

The iron soap formed by precipitation of suds with iron protosulphate is of a rich brown color, and dissolves readily in coal oil to a fine transparent varnish. That of copper is of a splendid green tint. The defect of these, as pigments, is a lack of the property of "covering." With coal oil as a solvent, the resulting varnish is too tender and brittle; probably linseed oil would be better. Lead and silver give white precipitates with suds, and that of gold is purple.

A Library for the Working Classes. The Manufacturers' and Village Library of Great Falls, N. H., now contains over five thousand volumes, to which every girl that works for the corporation can have access for the trifling sum of fifty cents per year, and all other persons for one dollar.

Mortising Machines.

America, and by "America" the European world at least always understands the United States, is renowned for the perfection to which it has carried labor-saving machines. Stimulated by the high price of labor, to a very great extent, our mechanics have improved on the old-fashioned ways of working, and have substituted almost living machines for the time-robbing manual labor.

Considerable attention has been given to the improvement of wood-working machinery, which is said to have been brought to a more advanced state here than in any other country. Not the least important branch of this class of mechanism is that of mortising timber. The slow process of cutting out the wood by mallet and chisel is now confined to very limited operations. But in cases where a large amount of work is turned out, especially when articles are reduplicated, we use our excellent machines.

Among the latest of such improved devices which come to us well recommended are the two which we illustrate. They were invented by Mr. D. L. Gibbs, who, we are informed, has had a long experience, and has devoted the study of years to perfecting his ideas. He has obtained patents for the same, which he has assigned to the manufacturers, whose address will be found at the end of this article.

The rail-car mortising machine, Fig. 1, is substantially built and has stood severe tests, it is stated, both in the United States and in England. The rest has a solid support, can be raised or lowered as desired, or turned to any desired angle. The apparatus for reversing the chisel is arranged, in connection with a pin over the treadle, so that it can be stopped in its upward motion at any point, when making shallow mortises. The treadle, when pressed down to the floor, is held by a catch, and so arranged that it can be instantly thrown off by the foot. The auxiliary boring attachment has a horizontal and vertical adjustment of twelve inches. All holes for bolts, etc., can be bored when the timber is in place for mortising. Composition boxes and hardened steel parts are used whenever necessary for the easy running of the machine.

The hub mortiser, Fig. 2, is designed for boring and mortising hubs of any size up to twelve inches in diameter and sixteen inches in length; and with the addition of an extra rest (not shown in the cut) it is capable of doing common square mortising in timbers not less than twelve inches deep and eight inches thick. The rest is tilted by a conveniently-placed handle, so constructed as to be stopped exactly at any requisite point. The rest, and also all the apparatus connected with it, is attached to a sliding plate on the post, admitting of its being moved up and down without changing the bevels. For giving the length of even or zig-zag mortises, there are stop nuts on a screw rod before the carriage, which can be adjusted by means of a stop-lever operated readily with one finger of the hand when holding the wheel.

The boring-arbor is driven by a belt from the counter-shaft which drives the mortiser, and fed by the foot, as this can be done more easily and quickly than by the hand when much work is done. The ball is suspended by a malleable iron lever at the top of the post, thus drawing up the joints in the same direction as the stroke of the chisel, and thereby avoiding much of the jar and rattle common in other machines. A spring attached to the rod inside of the post gives a quick upward motion to the treadles, lessening the weight of the ball and rendering it easier to depress the treadle. The balance-wheel head is connected at the top and bottom and held securely to the four corners of the post by adjustable packing. The dial-ring is accurately spaced for from ten to eighteen spokes, and held by a spring, conveniently arranged for turning.

These machines have been extensively experimented on and improved, and have been subjected to thorough tests with great success, as is claimed. They are manufactured by Messrs. R. Ball & Co., of Worcester, Mass., who may be addressed for further particulars.

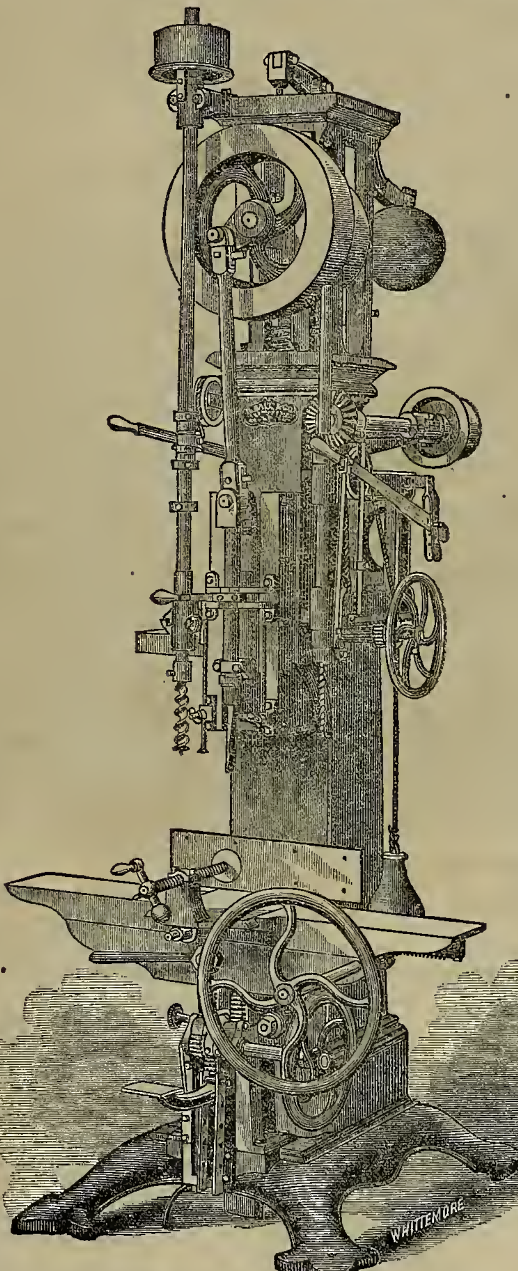

FIG. 1—RAIL-CAR MORTISING MACHINE.

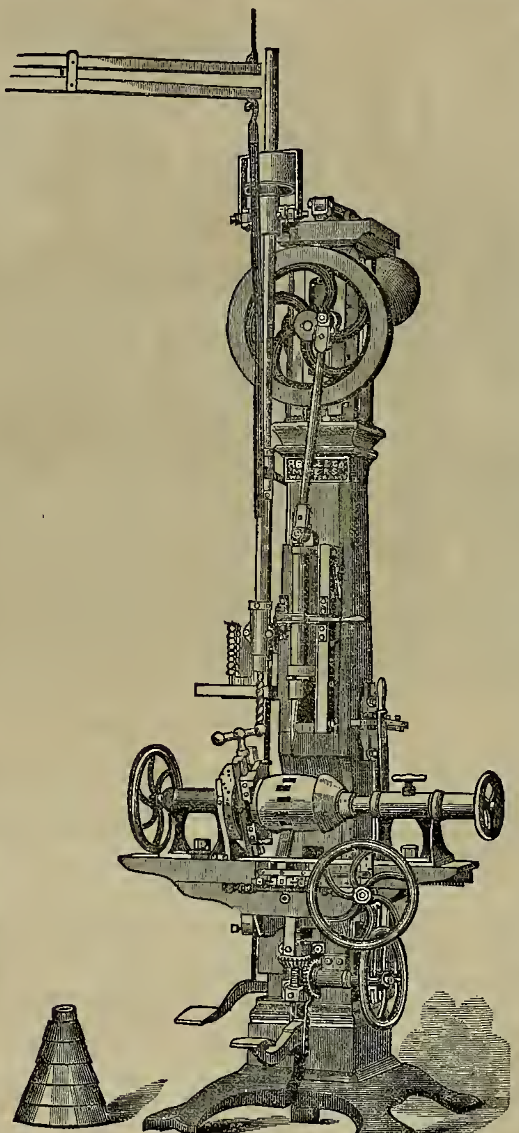

FIG. 2—HUB MORTISING MACHINE.

The Basalts of Oregon.

At a late session of the Academy of Science at Washington, Mr. R. W. Raymond read a most interesting paper on the basalts of Oregon, Washington and Idaho. After speaking of the Dalles particularly he went on to say that on the road from Dalles City to Cañon City, along the Sante river, was a tremendous thickness of basaltic overthrows two thousand feet high. The river had taken its way through the chasm of the original upheaval and worn it deeper. He explored the singular phenomena of the caves north of the Dalles. There was no ice in Portland last summer when he visited the place; but a few miles further it was abundant: and, on inquiry, he learned that it was mined from the ice caves forty miles up the Salmon river, near the foot of Mt. Adams. An expedition set out for the caves. They were not large, but beautiful, and filled with the purest ice in mid-summer. Here was a possible hint of the lost rivers which puzzle the discoverers. This was a volcano country, and the centers of lines of eruptions could be traced by the terraces. The ground under the horses' feet sounded hollow from the falling in of the roofs of old caverns from one to four miles in length, which were the old ducts of the lava. He had seen the same thing on Vesuvius in the eruption of 1859-'60, which was not from the crater but at the sides, as from a bleeding wound. The stream of lava cools at the sides and top, protecting the hot stream beneath. Finally the orifice becomes choked with stones and clotted lava at the eruptive point, and the lava flows away, leaving the duct empty, ending at some elevation of the surface which tore up the duct. In the ice caves, the roof had fallen at the corners, but on the sides and floors the smears of lava could be seen in fibrous masses, spirting on the roof-like door. In these caves the water trickles from thawing snow, in winter freezing as it falls, forming bergs of tons of ice reaching nearly to the top of the cave. This is much colder than common ice, and lasts all summer. Just below the lower line of Mt. Adams was to be found a miniature paradise, where all the flora of the Pacific coast grew luxuriantly, attended by myriads of humming birds which disappear for other regions with the flowers. The great Shoshone Falls, second only to Niagara, carved their way through basaltic rocks, remarkably distinct in their hexagonal and columnar form. Geological surveyors here can make no mistake in reading the text. He stood at one time over a cleft ten inches wide and five hundred feet deep. The river had eaten out below the basalt, which by gravity and cleavage had settled into a broken line, different columns separated by tufa settling sometimes without breaking. Four hundred feet the river has cut through the basalt, and there are two hundred feet of porphyry below the basalt. The Lost river is found on entering the cañon of the Snake river, where, from a perpendicular face of porphyry midway of the cliff, a cascade issues from the rock in a furious large stream. No water is to be found on the surface, but the settlers pretend to identify it with a river one hundred miles to the north. This was probably a volcanic drift from which the tufa had been wrought out of the way, and formed a channel underground for the water. The speaker wished to see this interesting region thoroughly surveyed by the Government.

A French Labor League.—Through the exertions of Mr. Th. Pergeline an influential association has been organized in Paris for the suppression of strikes throughout the French Empire. The efforts of the association will be directed to relieving the workmen from the tyranny of professional delegates, the evil influence of whom, as a class, is equally felt by employers and employed. Subscriptions are being freely given for aiding the attainment of the object in view, and in January next a prize of 5,000 frs. ($1,000) will be awarded to the author of the best essay under the title, "Suppression of Strikes," pointing out the means (not involving State intervention) most practical, equitable, and conformable with social equality, of rendering strikes henceforth inefficacious, and consequently impossible.—*London Mining Journal.*

A correspondent of the *Scientific American* recommends turpentine as a certain cure for lockjaw. He says: "Let any one who has an attack of lockjaw take a small quantity of turpentine, warm it and pour it on the wound, no matter where the wound is or what its nature is—and relief will follow in less than one minute. Nothing can be applied to a severe cut or bruise that is better than cold turpentine; it will give certain relief almost instantly. It is also said to be a sovereign remedy for croup. Saturate a piece of flannel with it and place the flannel on the throat and chest—and in very severe cases three to five drops on a lump of sugar may be taken inwardly. Every family should have a bottle on hand." It is a simple remedy and can be easily tested. In all serious cases application should be make under medical advice.

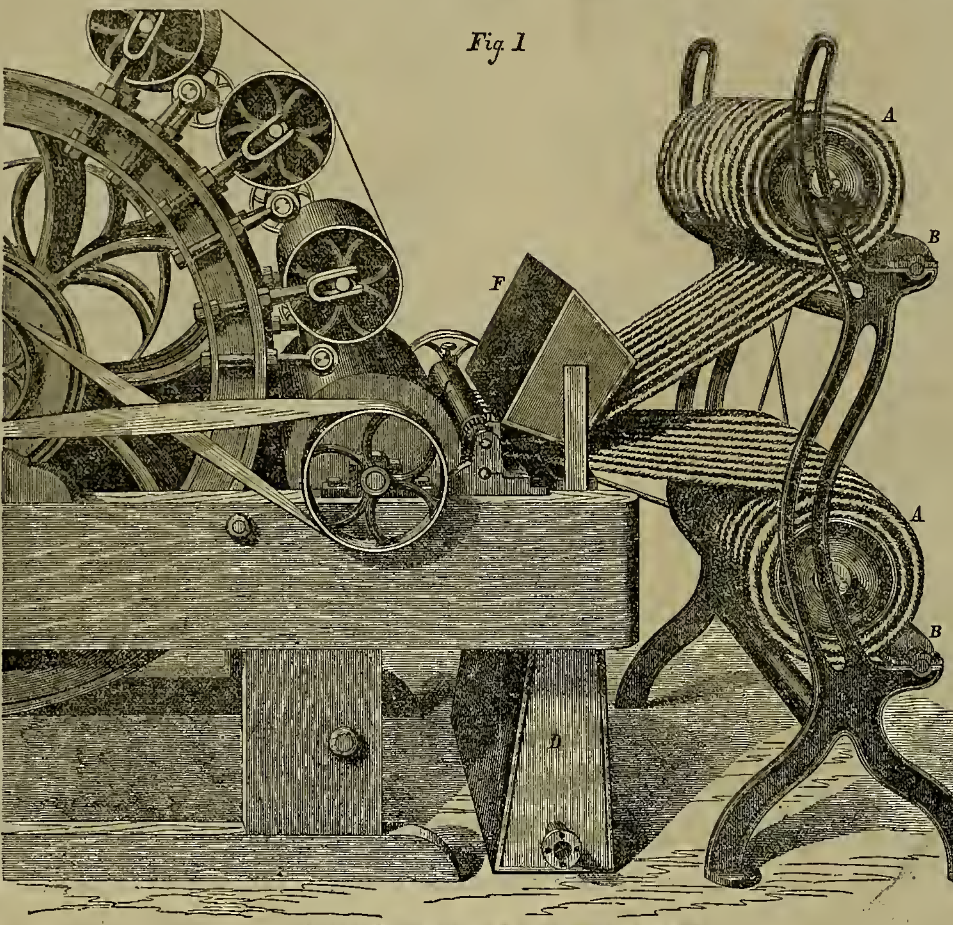
Served Him Right.—Ira E. White, of Wakefield, Mass. was lately sentenced to pay a fine of $75 and costs, for failing to provide sufficient food for his horse.

Device for Steaming Rovings.

In the manfacture of woolen or cotton goods, it is necessary to warm and moisten the strands of undressed wool or cotton which are to be carded, for the purpose of rendering them pliable, capable of being drawn out very fine, etc. The process of steaming has been employed for some time, but the manner in which it has been used has been open to certain inconveniences, which is the object of this invention to obviate.

The device is very simple and easily attached. Our first figure shows it applied to a carding machine, while Fig. 2 gives a sectional view, showing the interior of the steam reservoir.

Fig 1

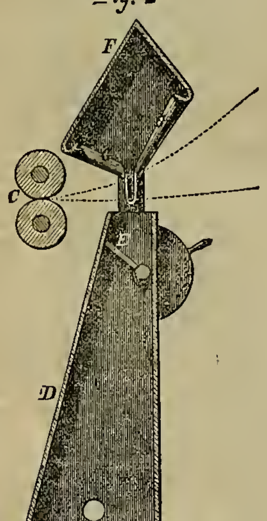


BARBER'S DEVICE FOR STEAMING ROVINGS.

From the rolls, A, on which the rovings are wound and which rest on wooden rollers, B, which revolve these rolls by friction, the rovings pass through a steam reservoir, D, and thence to the rollers, C, which feed the card cylinder. This steam reservoir is made of tin and composed of two parts. Into the lower part, D, the steam is admitted through a pipe, shown in the cut, and here it expands and passes up through the rovings into the upper part, F. In this place it condenses and the condensed water trickles down the sides and is carried away by interior gutters, G. In this way the rovings are reached by the steam alone, being protected from any condensed water, all of which is caught either in the lower part, D, or in the upper one, F.

While the rovings are thus gently and uniformly moistened—much more so, it is claimed, than by any other device used—there is also a great saving in the oil which hitherto has been used in quite considerable quantities for softening the rovings and rendering them pliable. Only one pint of oil, it is said, is necessary for a hundred pounds of roving with this arrangement; indeed, the use of oil can be done away with entirely, as is thought advisable when the goods are not to be scowered after weaving, in which case the fabric will then be much cleaner, and the colors much brighter and better.

Fig. 2



The annoyance, often quite serious in dry and cool weather, of the generation of frictional electricity, is prevented, and the wool can be worked equally as well in dry and cold as in moist and warm days. The amount of steam required is regulated by its admission into the reservoir and by means of the damper, E, which can be placed and held in any required position by means of a handle and pins.

The device is very highly spoken of, and seems to be a very efficient and desirable arrangement. It was patented by Solomon Barber, of South conveutry, Conn., to whom may be addressed any applications for further particulars.

◆

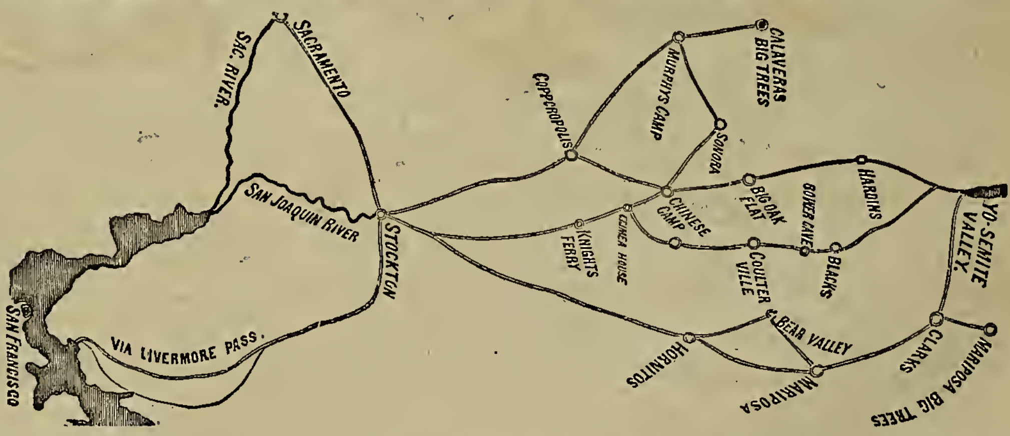
A Proclamation has been issued by the Governor of Arizona, calling upon every able-bodied man subject to military duty within the Territory to immediately aid in organizing the militia in order to take active measures against the Indians. The Apaches have been hitherto successful in committing murders and depredations, and the number of whites killed has been growing fearfully large. The Governor applied to Washington for assistance, and has been furnished with seven hundred and forty-four improved breech-loading guns and an ample supply of ammunition. As the military force there now is entirely inadequate to protect life and property, he will organize the militia and prepare for carrying on an aggressive war against the Apaches. The present state of things cannot continue, and the action of the Governor, backed up by the support of the citizens, will arouse the general government to taking more decisive measures. Helping themselves, as the Governor says, is the most effectual way to get help from others.

Route to the Yosemite.

The Yosemite Valley will probably be visited this year by a larger number of persons than ever before. New routes are being opened up, and the accommodations are being continually adapted to the wants of the travelers. There are several roads by which the valley can now be approached, each of which has its advantages and disadvantages.

The newest route, which was opened last year and traveled by over 600 persons, is by way of Chinese Camp and Hardin's. It has the advantage of being the most direct way and of saving considerable horseback riding, besides leading through a fine country. Parties leave San Francisco on the afternoon cars or boat for Stockton. Every morning a stage leaves this last place at six o'clock, and carries the passengers to Chinese Camp and to Hardin's, and thence horses are taken to the hotels in the valley, a distance of only eighteen miles. On the way one passes directly through the Tuolumne Grove of Big Trees, which alone is worth the whole cost of the trip. By leaving Stockton at six o'clock in the morning the tourist arrives at Chinese Camp at four in the afternoon, then rides fifteen miles to "First Garrote," where he spends the night, and the next day continues by stage over a well-graded mountain road to Hardin's, where the trail begins. Arriving here, those accustomed to horseback exercise may at once start off, reaching Hutching's Hotel in time for a late dinner, and in this way making the entire trip from Stockton in thirty-eight hours. Those who are unable to push on so rapidly, can rest during the day and night at Hodgden's, reaching the valley the next day.

This shortening of the route will recommend itself to many, particularly to ladies. It is highly spoken of by those who have traveled it, and those intending to visit the Yosemite would do well to talk the matter over with the gentlemanly agent, Mr. E. Harrison, who may be found at the Grand Hotel in this city, or who will call on any one who desires it and make any necessary arrangements.



Gold and Gold Mining.

Eds. Press:—The *Overland Monthly* for June contains an article headed "Gold and Gold Mining," in which the writer gives statistics to show that in Victoria they are making large profits from quartz which yields no more than $2 a ton, and he states that the average yield of the quartz in that colony ($10) is the minimum at which quartz can be worked to a profit in California. He gives one example of a company at Ballarat, who crushed 7,543 tons of quartz, which yielded only $2 a ton, and which cost $1.30 a ton for raising the quartz and extracting the gold, including wear and tear of machinery etc., and yet paid in dividend to the shareholder $10,500! If the writer will exercise himself a little in addition and subtraction, he will discover that the manager of the company performed a wonderful feat.

Again, if the writer will refer to the reports of Ross Browne, he will discover that, in some instances, they have been and are working quartz mines in California at a cost of less than $5 a ton.

The same statement was made in a similar communication to the *Bulletin* some months ago (February 16th) and passed unnoticed. The aims and high character of the *Overland Monthly*, will not admit of such errors. M.

◆

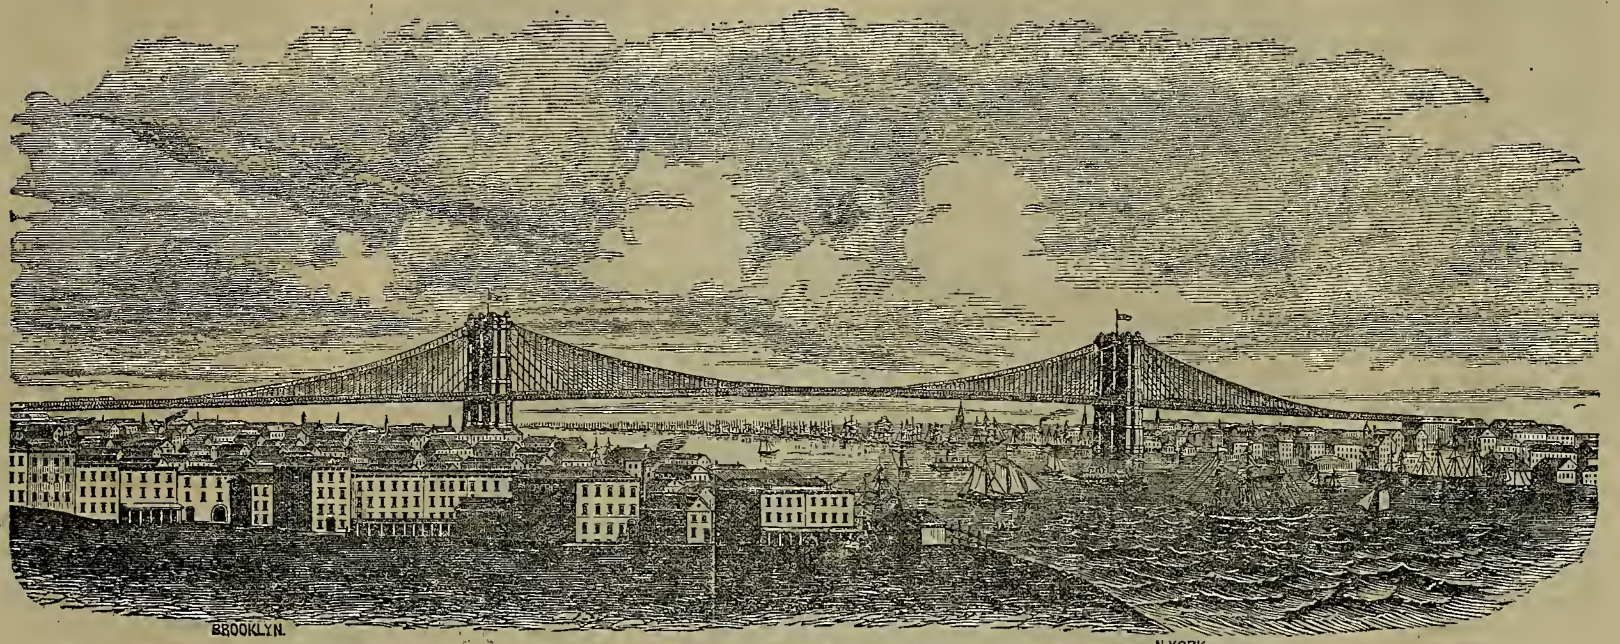
Not Digestible.—The Willamette *Farmer* says: "Mr. Morse, Warden of the Penitentiary, informs us that from the stomach of a cow killed at that institution during the week, was taken the following articles of 'hardware:' Forty-five nails, of different sizes; one piece of endless chain; piece of blade of jackknife, 1½ inches long and sharp; one piece copper; one 8-ounce tack; and a black rock about the size of a robin's egg. None of the articles are in a very forward state of digestion."

Good Friday.—The Grass Valley *Union*, of 26th, says: Yesterday Mrs. Murray received from her husband, David Murray, $125 worth of bullion from Auburn, that being Dave's share of the proceeds of eight loads of rock from the Good Friday ledge.

The East River Bridge, New York.

One of the greatest of engineers whom America has possessed, and one of the first in the world in his particular branch, was the late John A. Roebling, of Trenton, N. J. This talented engineer had made a specialty of the construction of suspension bridges and had built two of the boldest in the world—that at Niagara Falls and that at Cincinnati. His last and greatest work, however, was the planning of the East River Bridge, which is to be over a mile long and 130 feet, clear, above the channel of the river. Mr. Roebling died before his plans were followed out; but his projected work is to be carried on to completion, its execution being entrusted to the care of his son.

Our engraving, taken from the *Manufacturer and Builder*, shows the general appearance of the projected bridge, looking down the river. Its importance will be realized when we remember that fifty-two millions of people are yearly transported across the stream on the present comparatively inefficient ferry boats. Some idea of the magnitude of the work can be obtained from the following description:



VIEW OF THE SUSPENSION BRIDGE, NOW BEING CONSTRUCTED, TO CONNECT NEW YORK AND BROOKLYN.

There are two piers, as shown in the cut, 1,620 feet apart and 280 feet high, so that the largest ships may pass beneath. The weight of the bridge will be 3,600 tons, and it will sustain a transitory weight up to some 1,400 tons, giving a total of 5,000 tons. Each pier will contain over 900,000 cubic feet of granite, will be hollow, with a base measuring 134 by 32 feet at the water line, and will weigh more than 70,000 tons. To support this weight with safety, the surface of the lower part of the foundation will be 17,000 square feet. In each pier there will be two arches for entrances to the bridge, each being 32 feet wide and 120 feet high, and giving passage to a railroad track, a carriage way, and a sidewalk. The bridge will be sustained by four cables made of parallel steel wire, stretched in a bundle nearly a foot thick. These will be anchored in two solid walls which are 3,794 feet apart. Beyond these points, on each side, the approaches are built of arched masonry, commencing at the City Hall in New York and at the junction of Fulton and Sand streets in Brooklyn. Each cable enters through the masonry of the anchor-walls to a distance of twenty feet, and then connects with anchor chains 130 feet long, which form a downward curve so as to convert a part of the tension into downward pressure. The pull on each will amount to about 5,600 tons. But reliance is not placed alone on these huge cables. The bridge is secured likewise by stays from the tops of the piers to the bottom of the bridge, which, it is asserted, will hold the bridge, even if the cables should break, although they would not prevent its sagging in the middle in this case.

In building such a bridge not only must the weight be held up, but care must be taken to prevent its being swayed by heavy gales. For this purpose the cables are not laid in parallel lines, but the outside ones are much further apart at the piers than the width of the bridge, and approach each other, while the reverse is the case with the middle cables.

The first and most difficult step is laying the foundation of the piers; a work which has evoked a display of the highest engineering talent. The general plan of effecting this on the Brooklyn side, where rock is found only at a depth of ninety-seven feet, is as follows: The shore is first dredged out, and then a large caisson floated into position at high tide and firmly secured as the water recedes. The ground beneath the caisson will then be excavated, until the huge affair, sinking by its own weight as the work progresses, shall have reached a point thirty feet below low tide, when additional timber will be laid on top of it to the height of fifteen feet, and filled in with concrete; and when the whole has become firmly fixed in place, the tower will be built on the solid foundation thus obtained.

The caisson is a huge structure, 168 feet long, 102 feet wide and 15 feet high, built of white pine timbers, a foot square, and strongly bolted together, with the seams tarred to render them water-tight, and a sheathing of tin, between two of felt, placed between the outside layers of timber, to make the affair air-tight. The whole does not form a solid mass from top to bottom, but contains a large chamber below, about nine feet high, with sloping walls, the lower part of the four sides of the caisson around this chamber or cavity having a wedge shape, in section, eight inches wide at the lower edge and 8¼ feet wide at the top of the chamber. This wedge-shape facilitates the sinking of the caisson, and its sharp lower edge is very strongly constructed. To prevent the corners at the bottom from spreading, great care is taken, and in the second course, at each corner, a knee of hardwood timber, extending twenty feet each way, is inserted.

Six shafts, lined with half-inch boiler iron, pass through the roof of the caisson. Two are water-shafts, rectangular, 6½x7 feet, in which the water collecting in the caisson will rise, forced by the atmospheric pressure. Two are man-shafts, of circular shape, through which the workmen will pass and the earth be hoisted. Two are air-shafts, also circular, and 3½ feet in diameter. Air will be forced into the chamber, expelling the water and enabling the laborers to work on the bottom. As fast as these excavate the earth, they will deposit it around the shafts, through which a dredging machine will lift it and dump it into the scows. The interior will be lighted by gas. The caisson contains 1,500,000 feet of lumber, 100 tons of wrought iron in the shape of bolts, angle-irons and plates, and weighs from 2,500 to 3,000 tons.

The work of dredging was commenced on the 3d of January. The bottom was composed of clay, gravel and loose boulders; and to render it easy for this process piles were driven and then removed, and in the holes thus made shells were deposited and exploded. Many of the boulders were over ten tons in weight and were destroyed by explosion through the means of divers. The work was prosecuted at night, and cost about $35,000.

On the nineteenth of March, at high tide, the monster caisson was launched at the yard of the builders, Messrs. Webb & Bell, at Greenpoint. This was effected without difficulty, although itself a work requiring great mechanical talent. Without a single mishap the huge structure slid down the ingeniously-constructed ways into the water. Then the air-pumps, driven by a steam engine on deck, were set at work, and thus the caisson was raised considerably. It was then taken in tow by steamers and attached to a neighboring pier, where work on top of it was continued.

On the third of May, the place for it being ready, it was towed by four steamers and laid upon its bed near the Fulton ferry slip, where a dock had been built for it, into which it fitted exactly. Here the work of excavation is going on, and no trouble is anticipated, unless, perhaps, in sinking the edges may come upon large boulders.

Every obstacle, and such present themselves at every step, has been successfully overcome thus far, and we doubt not that the skillful engineers who have the matter in charge will be able to complete their gigantic undertaking. We have not sufficient space to speak more of the details of this most interesting work. In the boldness of its conception, the ingenuity displayed in its execution, and its magnitude and importance, connecting as it does two great cities, it will ever remain a colossal monument of American ingenuity and American skill and energy.

Ocean Cables.—There are now sixty-four ocean cables in different parts of the world, with an actual length of insulated wire amounting to 27,402 miles. The earliest line, laid in 1851, is that across the British channel from Dover to Calais; the latest, in 1870, that between Bombay and Aden, which is 2,881 miles long. The longest one is that from Brest, France, to St. Pierre and Duxbury, Massachusetts, having a total length of 3,887 miles. Contracts have been made for the completion within one and two years of eleven additional lines, which will be, in all, 20,828 miles long. But much longer than any at present existing or contracted for, is that for which Mr. Cyrus W. Field is now working before Congress. This is to extend from San Francisco to Japan and China by way of the Sandwich Islands or the Aleutian Archipelago, and will be six to seven thousand miles long. But having a mid-ocean station, the difficulties of the undertaking are greatly reduced and brought fairly within limits known to be possible by the existence of other lines. If carried out this will complete the telegraphic girdle around the globe and, with its connections, bring our commercial centers into close communication with all parts of the world.

* * *

California woolen blankets have the established reputation of being superior to all which are imported. We have used several manufactured by the Marysville woolen mills, which we consider as among the very best. Marysville is located very favorably with regard to the wool-growing interest of a large section of our State, and the proprietors of these mills have the opportunity of securing some of the choicest staples raised in California. Improvements have been introduced by them during the last year, their manufactory extended and its producing capacity greatly increased. Messrs. L. & M. Sachs, corner of Bush and Battery streets, are the agents for San Francisco.

* * *

Government School of Mines.—It is proposed by parties East to have mining engineering taught at West Point. We imagine that this will not amount to anything more than a proposition. The one great advantage from such a school would be that we could be certain that a graduate from there had really studied his profession faithfully, which guarantee we have from no other mining school at present.

High wind has done considerable damage to the fruit crop in the vicinity of Stockton.

Bridal Veil Fall, Yosemite Valley.

One hundred and forty miles east of San Francisco, on the western slope of the Sierra Nevada, thirty miles from their summit, and at an elevation of over four thousand feet above the level of the sea, lies the pride of California, the boast of the United States and one of the great wonders of the world—the Yosemite Valley. Unparalleled of its kind, it is the perfection of beauty and sublimity.

THE BRIDAL VEIL FALLS, YOSEMITE VALLEY, CALIFORNIA.

We have no intention of giving a description of this valley, so well known by report and personal experience. We give our readers, however, a view of one of its most beautiful features, the Bridal Veil fall, which has elicited the rhapsodies of writers and the highest efforts of some of our best artists. Situated two miles from the lower end of the valley, and being the only one of the noble cataracts visible to the tourist on approaching or leaving the enchanted spot, it has attracted special attention. About seventy feet wide in June, leaping a distance of a thousand feet, and waving from side to side, like the fluttering of a white veil, it is a most beautiful sight. "As I think of it," writes Starr King, "I lose quickly the impression of the widening of its watery trail before it struck the rocks to thunder from them; I do not dwell either on the fascinations of its ever melting and renewing tracery, nor on the brilliance of its iris banners, that are dyed into its leaping mists and flying shreds; I can recall for my supreme delight only the curve of the tide more than eight hundred feet aloft, where it starts off from the precipice, and the transparency of its vitreous brink, with the edge now and then veiled with a little curling misty vapor, when the wind blew hard against it, but generally tinged with a faint apple-green lustre."

To those of our readers who have visited this wonderful vale, our illustration will recall the hours of the highest enjoyment;

to those who have been unable to partake of this choicest of pleasures, it will give some idea of one of the grandest beauties of Nature, a foretaste of the rarest treats within the reach of mankind.

On another page we give a sketch map of the location of other places of interest contiguous to the routes to Yosemite, together with some information regarding the new and popular means of conveyance opened last season via. Chinese Camp.

Machinery for the Farm.

Farming machinery is, as a general thing, very roughly made and clumsily put together. A mechanic prides himself greatly in the perfectly fitting gearing and true and steady motion of the machinery he uses. The greatest mathematical nicety is observed in its construction. Its setting is gauged to a hair, so that no power may be lost in uneven motion or friction. But anything seems to be considered good enough for the farmer, and any sort of usage good enough for the machine after the farmer gets it. Rough castings are frequently warped out of true, and not even dressed, but geared together as most convenient for the manufacturer. An unequal strain and motion is the consequence of such disproportional machinery, and a loss of power is also entailed. It is better that two prices be paid for good machinery, than that a poor machine be furnished for nothing.

The farmers of California always demand the best, or what they think the best, regardless of cost, and none but the very best machinery, finished perfectly, and substantially fitting, should be tolerated; and instead of leaving farm machinery exposed out of doors to the shrinking, swelling and rotting and warping of the sun, rains and weather, the *prudent* husbandman will house his machinery and keep it in repair. The bearings and boxings of farm machinery are generally too small. Where the bearings are large, much greater strength is given to the machine, and it will last, in good order, much longer. Too little attention is given to this important principle, more particularly in the manufacture of portable machines. Portable engines, harvesters, mowing machines, etc., are generally greatly at fault in this respect.

The care of machinery is a subject of great importance. Every farmer is aware of the great difference in the running and working of the same machinery in charge of different men. Aside from properly handling the team, or power, the difference is sometimes one-half in effective service. Constant attention and watchfulness are required to work and take care of machinery. We have known men to take a pride that almost amounted to an affection for the machinery under their charge. Such a person, with proper instruction and understanding, may safely be trusted.

The boxing of the machinery should never be set so tight as to bind and heat; but should fit so close as not to allow any rattling or clattering. Much power is frequently lost by unsteady motion and by unnecessary friction.

Another most important matter, and one too frequently neglected, is the oiling of the bearings, and the cleaning from all clogging and "gumming," of all parts of the machine. It is poor economy to spare the oil, especially where the greatest amount of speed is centered. We have known the pitman boxing to cut badly—to be nearly ruined in one day's running of a reaper by a careless hand, and all for the want of a little oil. The slightest tendency to heat may be readily detected by touching the boxing with the fingers, which should be frequently done and always attended to. The ear soon detects the least thing wrong in the running of the machinery. There is music in the smooth and easy clipping of a perfect mower, and agony in a rattling or binding machine. The low, even hum of a thresher is quite different from the harsh, uneven tremor of a badly-working one. Indeed, while the economy of power and the effectiveness of machinery depends so much on its construction, and so very much on its management and care, it is of much importance that farmers give more attention to the principles involved. S. H. Herring.

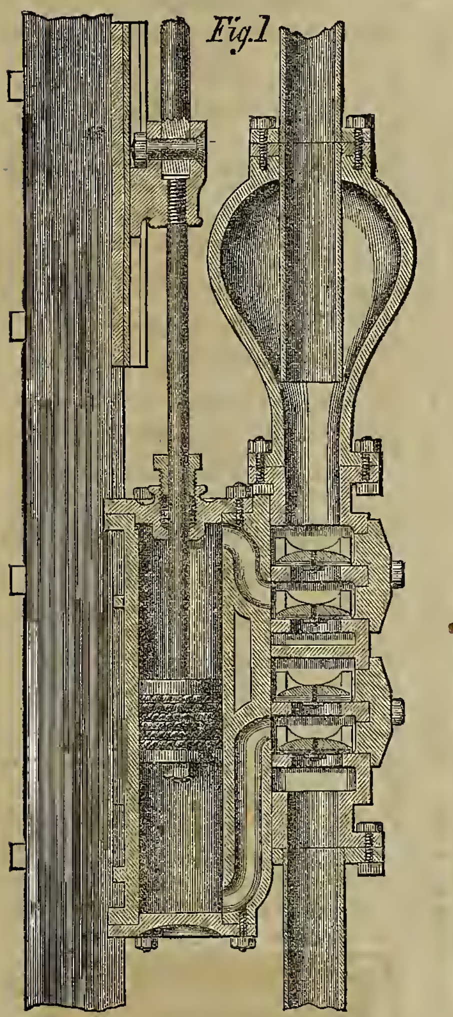
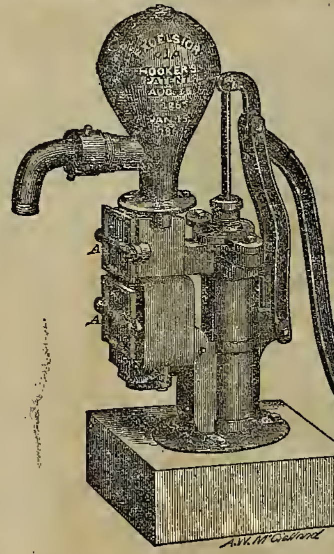
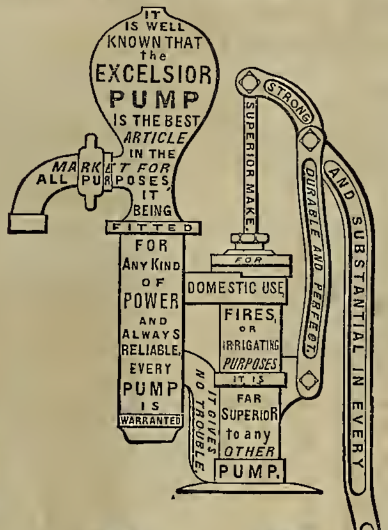
EXCELSIOR IMPROVED DOUBLE-ACTING SUCTION AND FORCE PUMP.

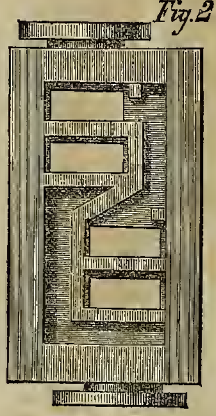
HOOKER'S PATENT, August 13, 1865, and January 15, 1867.



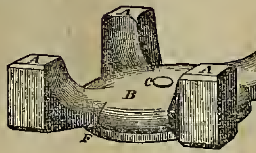




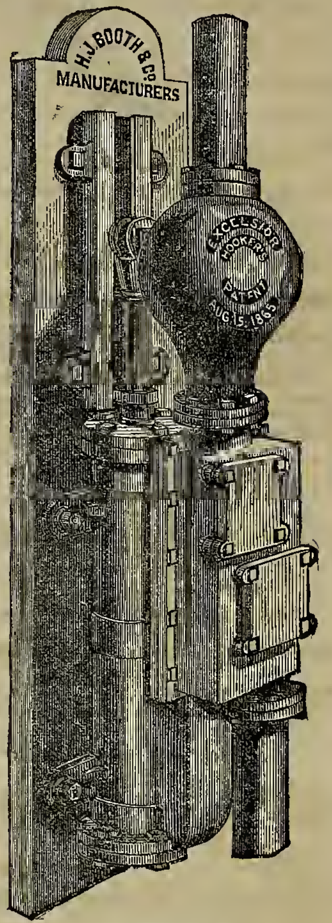
IT IS WELL KNOWN THAT the EXCELSIOR PUMP IS THE BEST ARTICLE IN THE MARKET FOR ALL PURPOSES, IT BEING FITTED FOR ANY KIND OF POWER AND ALWAYS RELIABLE, EVERY PUMP IS WARRANTED
SUPERIOR MAKE. FOR DOMESTIC USE FIRES, OR IRRIGATING PURPOSES IT IS FAR SUPERIOR to any OTHER PUMP.
IT GIVES NO TROUBLE.
STRONG DURABLE AND PERFECT.
AND SUBSTANTIAL IN EVERY RESPECT.



VALVE BOX.



VALVE.



We call the especial attention of all Millwrights, Miners and Farmers to this very superior Force Pump. It is more simply constructed, more durable, and has larger and more direct ports for receiving and discharging water, and warranted to furnish more water than any other pumps of equal caliber. It has Poppet Valves, which can not be wrongly placed in the Pump. The Fair of the Mechanics' Institute, held in the city of San Francisco, awarded the owners of this Pump, FOR ITS SUPERIORITY, A FIRST PREMIUM AND SILVER MEDAL. Suitable for DEEP WELLS, Factories, Mining, Breweries, Sugar Refineries, Tanneries, Railroad Purposes, Drainage, Irrigation, etc. As the above Pumps are already in use in the principal Sugar Refineries, Factories, Rolling Mills and Gardens in this city, reference may be had where they are working. ☞ See circular for particulars.

General Agents.—MESSRS. BRITTAN, HOLBROOK & CO., 111 and 113 California street and 17 and 19 Davis street, are Agents for the sale of the Excelsior Pump, who make liberal discount to the trade. H. J. BOOTH & CO., Union Iron Works, First Street, corner of Mission, San Francisco, who manufacture and have the sale of the Excelsior Pump.

V. CUSHING, Proprietor, San Francisco.

☞ We have BRASS-LINED, BRASS PISTON and BRASS VALVE PUMPS, at greatly reduced prices. Also STEAM PUMPS. ☜

THE EQUALIZING INSTITUTE.

SOMETHING NEW.

The Equalizer,

A TRUE GUIDE

—TO—

HEALTH.

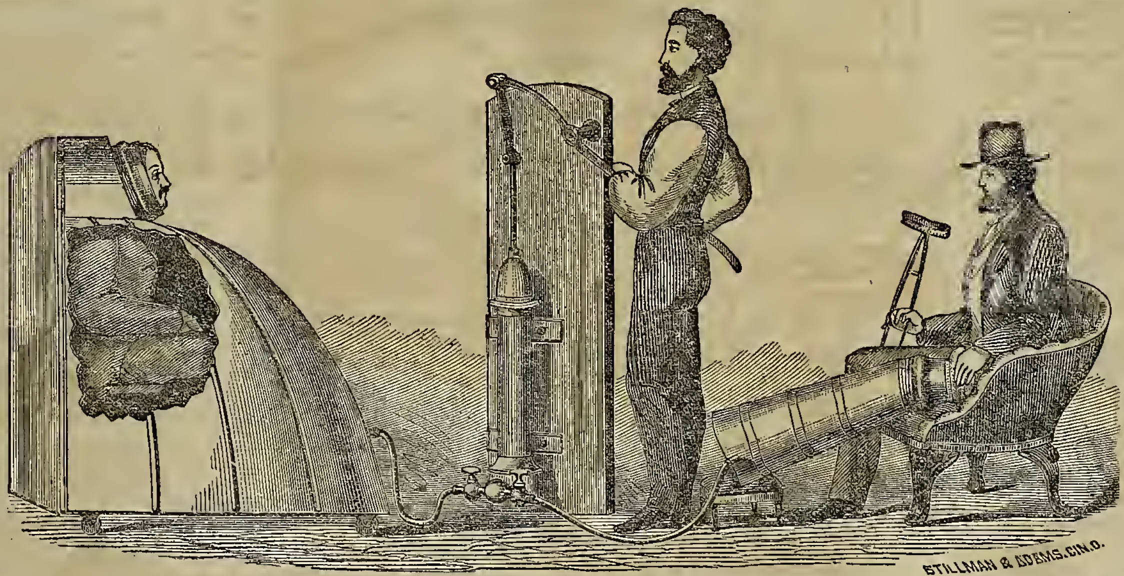
CURES

All Chronic Diseases

—BY—

VACUUM.

This treatment causes a thorough circulation of the blood throughout the system, creates new life, restores the GENERATIVE ORGANS, and reinstates perfect health.



STILLMAN & ADEMS.CIN.O.

The Following Diseases

CAN BE CURED

By this System:

Paralysis, Nervous Debility, Neuralgia, Dyspepsia, Asthma, Curvature of the Spine, and other Spinal Affections; Sciatica, Palsy, St. Vitus' Dance, and Derangement of the Mind; Pro Lapsus Uteri, Obstructed Menstruation, with all their concomitant diseases, Impotence, and all kinds of Weakness of the Generative Organs, can be cured. It breaks up congestion and inflammation in every part of the system.

All those treated with any of the above diseases can be speedily cured by application of the Equalizer.

Ladies will be treated by a competent Female Physician, who graduated in a New York Institute.

OUR BREAST GLASS

Is not simply an elevator of the breast for ornamental purposes, though it is true it will increase the size of the breast to any extent desired; but this is the least of the advantages derived from its use. For the health of both mother and child, every mother should nurse her own babe. The benefit derived from the application of this Glass will enable her to do so with pleasure.

CONSULTATIONS

Can be had with the undersigned at all hours at the office of the Equalizer,

No. 650 Howard Street,

SAN FRANCISCO.

RADICAL CURE OF PARALYSIS.

P. Winsdor, having suffered severely from four sun strokes, in the last two years from four strokes of total Paralysis and loss of speech, had recourse to the Equalizer as a treatment for same, and by means of the Equalizer was perfectly cured in the astonishing short period of four months, and as a proof of the above he can be seen at the Equalizing Institute, Howard street.

SAN FRANCISCO, February 17th, 1870.

P. Winsdor—Dear Sir:—I am 70 years old, have been Paralyzed two years on my right side. After using the Equalizer one month I find myself much improved. My leg, which would drag the ground when walking, now comes up as usual; my right arm, which was drawn round in front, now hangs by my side as formerly; my fingers, which had lost their sense of feeling, have been greatly improved, so that I can feel the smallest article. I was also troubled with the Rheumatism in my left arm and shoulder, which has been entirely removed during the month's operation. In many other respects I am much improved.

Yours, Respectfully,

[Signed] DAVID COLLINS,
208 First street.

[The above letter is in Mr. D. Collins' own handwriting, and can be seen at the Institute.]

SAN FRANCISCO, February 18th, 1870.

P. Winsdor—Dear Sir:—I am 32 years old, and have been Paralyzed in my right leg for three years, during which time I could not walk without a crutch and cane, but after a treatment of four months by the Equalizer, am able to walk quite comfortably without any assistance, and strongly recommend the Equalizer as a cure for the Paralysis. Yours Respectfully,

AARON MARKS,
Auction Store, corner of California and Kearny streets, San Francisco.

SAN FRANCISCO, February 17th, 1870.

Dear Sir:—In January, 1870, I suffered severely from Rheumatism, so much so as to prevent me from practicing in my profession as a Dentist. I tried the Equalizer as a remedy, and in twenty minutes after the first application experienced great relief; four more applications cured me perfectly, and I fully recommend the Equalizer as a certain and rapid cure for the Rheumatism.

Yours Respectfully.

DR. J. W. WINTER, Dentist,
No. 405 Kearny street.

N. B.—Ladies desirous of being treated by the Equalizer will be attended on by a Female Physician, who graduated at a New York Institute, and can obtain first class lodgings at moderate prices at the Institute. Those who wish to be treated at their residence can be accommodated.

Proprietor of the Equalizing Institute,

PHINEAS WINDSOR, E. C.

THE large majority of United States and Foreign Patents granted to inventors on the Pacific coast during the past few years, have been obtained through the agency of DEWEY & Co., publishers of the SCIENTIFIC PRESS. Established in the year 1860, we have an extensive patent library, with full record of cases on this coast, and can give the best and most reliable advice as to the patentability of new inventions.

Sheffield Scientific School
Of Yale College, New Haven, Conn.

This department of Yale College, instituted in 1840, and endowed with the National Land Grant in 1865, furnishes advanced instruction in the various branches of Mathematical, Physical, and Natural Science.

The School is under the direction of the President of the College, a Board of thirteen Professors in differe special ties, and six assistant instructors.

Regular courses of study, leading to the degree of Bachelor of Philosophy, conferred by Yale College, are arranged as follows: 1—CHEMISTRY AND MINERALOGY. 2—CIVIL ENGINEERING. 3—MECHANICAL ENGINEERING. 4—MINING ENGINEERING AND METALLURGY. 5—AGRICULTURE. 6—NATURAL HISTORY AND GEOLOGY. and 7—SELECT COURSE.

Advanced students are also admitted to optional courses, and if already College graduates, are received as candidates for the degree of Doctor of Philosophy.

Tuition, $125 per year of forty weeks.

The Libraries, Museums, Laboratories and Apparatus accessible to students, are varied and extensive.

For copies of the Annual Circular and Report, letters may be addressed to the "Secretary of the Sheffield Scientific School." New Haven, Conn. v16-1y16p

"Live and Let Live,"

Is a good old adage, and we shall adopt it as our own. We do not pretend to do work at "less than cost," as some people advertise to do; but we do claim to do all kinds of printing as cheap as it can be done on this Coast—and we believe as cheap as it is DONE in Chicago. Customers, in the country or city, are invited to call in person at our office, or send their orders by mail or express, and they will be fairly dealt with.

LEA & PERRINS'

CELEBRATED

Worcestershire Sauce.

CAUTION AGAINST FRAUD.

Declared by Connoisseurs to be the only good SAUCE The success of this most delicious and unrivalled Condiment having caused certain dealers to apply the name "Worcestershire Sauce" to their own inferior compounds, the public is hereby informed that the only way to secure the genuine is to ASK FOR LEA & PERRINS' SAUCE, and see that their names are upon the wrapper, labels, stopper and bottle.

Some of the foreign markets having been supplied with a spurious Worcestershire Sauce, upon the wrapper and labels of which the names of Lea and Perrins have been forged, L. and P. give notice that they have furnished their correspondents with power of attorney to take instant proceedings against manufacturers and vendors of such, or any other imitations by which their right may be infringed,

Ask for LEA & PERRINS' Sauce and see name on wrapper, label, bottle and stopper.

507 MECHANICAL MOVEMENTS.

PUBLISHED BY

DEWEY & CO.

LIST OF CONTENTS.

Æolipile.

Balance, Compensation: Barometer; Blower, Fan; Brake, Friction.

Cams; Capstans; Centrolinead; Clutches; Chasers; Clamps, bench and screw; Cock, four-way; Column, oscillating; Compasses, proportion; Counters of revolutions; Coupling, union; Crank—substitute for the, variable; Cranks, bell and compound; Cyclograph.

Differential Movements; Drag-link; Drill—Fiddle and Persian; Drills, Cramp; Drop; Drum and Rope; Driver, Pile; Dynamometers.

Eccentrics; Ejectors, Bilge; Ellipsograph. Engine, Disk; Engines—Rotary, Steam, Valve Gear for; Epicyclic Trains; Escapements.

Fountain, Hiero's: Fusees.

Gasometers; Gauge, Bisecting; Gauges, Pressure; Gear, Steering; Gearing—Bevel, Brush, Capstan, Conical, Crown, Eccentric, Elliptical, Face, Friction, Internal, Irregular, Multiple, Mutilated, Scroll, Sector, Spur, Step, Stud, Sun and Planet; Gearing—Variable, Worm; Governors; Guides; Gyroscope.

Hammers-Atmospheric, Bell, Compressed Air, Trip, Steam; Helicograph; Hook—Boat-detaching, Releasing; Hooks, Centrifugal Check; Hyperbolas, Instrument for Drawing.

Intermittent Movements.

Jack—Hydrostatic, Lifting; Joint—Ball and Socket, Bayonet, Universal.

Ladder—Folding, Self-Adjusting; Lazy-tongs; Level, Self-recording; Lever—Bell-crank or Elbow, Knee; Lewis; Link. Detachable Chain.

Machine—Bohnenberger's, Drilling, Polishing, Punching, Warp-dressing; Main, Flexible Water; Maintaining Power; Meter—Gas (wet and dry), Water; Mill—Barker's, Crushing, Tread, Wind; Miscellaneous Movements; Motion—Alternating Traverse, Rocking, Self-reversing, Shuttle; Motions—Feed, Link, Parallel, Pump, Traverse, Variable Traverse.

Pantograph; Parabolas, Instrument for Drawing; Paradox, Mechanical; Pendulum, Conical; Pendulums, Compensation; Pinion—Lantern, Mutilated, Slotted, Two-toothed; Power, Horse; Presses, Hydrostatic; Propeller, Screw; Pulley—Expanding, Friction: Pulleys—Anti-friction Bearing for, Chain; Pump—Air, Balance, Bellows, Chain, Diaphragm, Steam-siphon; Pumps—Double-acting, Force, Lift, Rotary; Punching Machine.

Rack—Mangle, Mutilated; Racks and Pinions; Ram, Montgolfier's Water; Ratchets and Pawls: Regulator—Gas, Watch, Reversing Motion, Self; Revolver; Rollers, Oblique; Rolls—Anti-friction, Drawing, Feed; Rulers, Parallel.

Saw—Endless Band, Gig, Pendulum; Screw, Archimedes, Differential, Double Reversed, Micrometer; Screws—Endless, Right-and-left Hand; Sectors; See-saw; Shears; Stamps; Stand, Mirror; Stop—for Hoisting Apparatus, for Lantern Wheels, for Ratchet Wheels, for Spur Gear; Stops for Winding Watches.

Test, Friction; Throttle, Spinning; Toggle-joint; Tongs, Lifting; Trap, Steam: Treadles.

Water, Machines for Raising: Weir, Self-acting; Wheel Cam, Lantern, Persian, Pin, Rag, Sprocket, Steering, Waved; Wheels—Crown, Mangle, Paddle, Water; Windlass—Chinese, Friction; Windmills; Wipers.

This book is bound in cloth, and embraces 122 pages. The illustrations are plain, and each figure is clearly described on the page opposite to it. It is a low-priced book for its kind, and there are few persons who have to do with machinery, or are interested in understanding the science and principles of motion, who will not be benefitted and satisfied by its purchase.

A liberal discount made to the trade. Single copies, $1—sent postage free. Address orders,

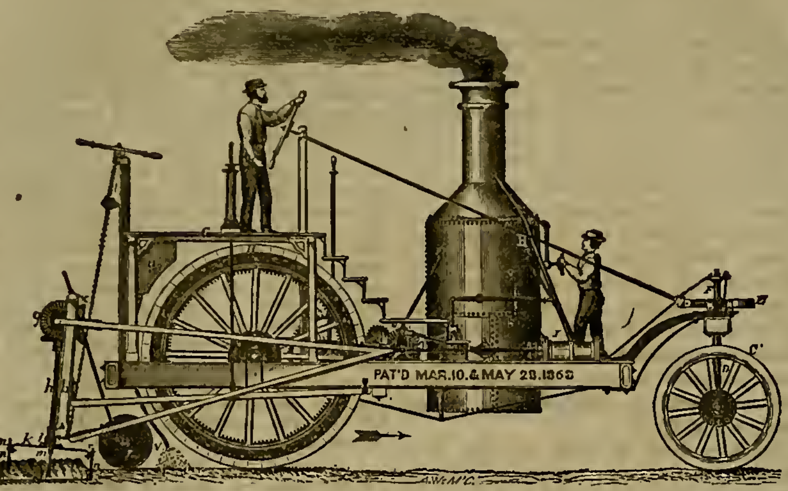
The Standish Patent California Steam Plow.



Capacity, from FIFTEEN to THIRTY Acres per day. The success of this invention for plowing large fields, is established beyond a doubt. Individuals, clubs, or companies desiring a more rapid and economical means of cultivating their farms, are invited to address, for the present, the inventor, PHILANDER H. STANDISH, care of CHAS. F. COFFIN, South Boston, Mass. He will soon return with a plow of improved construction.

Air—Daisy Deane.

'Twas down in the kitchen a turkey she was stuffing,
And trimming it with parsley fresh and green;
And the kettle on the stove was bubbling and singing,
When I first met my darling Daisy Deane,
None knew thee but to love thee, thou dear one of my heart,
Oh! thy cabbages were ever fresh and green;
Though the squash pie is gone, and stuffed hearts be eaten,
Still I love thee, my darling Daisy Deane.

While walking on the levee, she fell into the river,
And she floundered like a fish caught in a seine;
By the wetting she took cold and a racking cough soon followed,
It settled on the lungs of my darling Daisy Deane.
None knew thee, etc.

My bright flower seemed fading, like a rose that had fallen,
Though they dosed her with pills and kerosene;
For the doctors all agreed she'd die before the morrow,
Oh! my dear one, my darling Daisy Deane.
None knew thee, etc.

So down to the drug store I despondingly did wander,
To end my existence with a glass of glycerine;
But ALLEN'S PECTORAL BALSAM was placed within my grasp,
Just one bottle cured my darling Daisy Deane.
None knew thee, etc.

☞ Ask for ALLEN'S PECTORAL BALSAM, and see that the proprietor's signature (as below) is written across the wrapper in red ink. SOLD BY ALL DRUGGISTS AND GROCERS.

Isaac D. Allen

Depot—139 J Street, Sacramento.

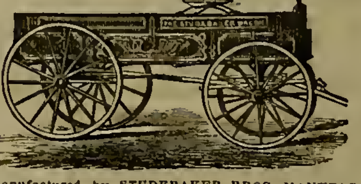
The Celebrated Studebaker Wagon,



Manufactured by STUDEBAKER BROS. MANUFACTURING CO., South Bend, Indiana. WAGON DEALERS, there are nine reasons why you should buy the above Wagon:

FIRST.—They are made of the best selected INDIANA TIMBER, thoroughly seasoned under cover.

SECOND.—They are made by experienced mechanics.

THIRD.—The lightest running and most durable Wagon in the market.

FOURTH.—Their Thimble Skeins never break, while all others do.

FIFTH.—Most uniform and best proportioned Wagon in the market; any part of one will fit another, while other makes will not.

SIXTH.—The only Wagon in which the SLOPE SHOULDER SPOKE is used; hence they have the best Wheel, which is actually the foundation of the Wagon, and should be carefully examined by persons buying.

SEVENTH.—They are sold only by responsible parties, and every Wagon is warranted to give entire satisfaction.

EIGHTH.—Because Teamsters will tell you they are the best Wagons, for all purposes, on the road.

NINTH.—Last, but not least, Studebaker Brothers are practical men, attend to their business personally, and do not entrust it entirely to foremen, as is generally the case in large factories; hence the superiority of their work over all others. Sold by

COPELAND & DEFREES,

Reading for the Hour.

SWISS WASHERWOMEN.—Curtis Guild, in his "Over the Ocean" sketches in the Boston *Commercial Bulletin* gives the following amusing account in Geneva: Returning back across the bridge to our hotel we saw a specimen of Swiss clothes-washing, which in a measure may suggest that reason why some of the inhabitants of this part of the world change their linen so seldom. Beneath a long wooden shed, with its side open to the swift flowing stream, were a row of stout-armed, red-cheeked women bending over a long wash-board, which extended into the stream before them. Seizing a shirt, they first gave it a wash in the stream, next it was thoroughly daubed with soap and received other vigorous swashes into the water, and was then drawn forth dripping, molded into a moist mass and beaten with a short wooden bludgeon with a will; then come two or three more swashes and a thrashing by the stalwart washerwoman of the garment down upon the hard board before her with a vigor that makes the buttons spatter out into the stream like a charge of bird shot. After witnessing this, I accounted for the recent transformation of a new linen garment by one washing into a mass of rags and button-splinters. This style of washing may be avoided to some extent by particular direction, but the gloss of glazing which the American laundries put upon shirt-fronts seems to be unknown on the continent.

DIARRHŒA is very common in summer time. Cholera is nothing more than exaggerated diarrhœa. When a man has died of diarrhœa, he has died of cholera in reality. It may be well for travelers to know that the first, most important, and most indispensable item in the arrest and cure of looseness of the bowels is absolute quietude on a bed; Nature herself always prompts this by disinclining us to locomotion. The next thing is to eat nothing but common rice, parched like coffee, and then boiled, and taken with a little salt or butter. Drink little or no liquid of any kind. Bits of ice may be eaten or swallowed at will. Every step taken in diarrhœa, every spoonful of liquid, only aggravates the disease. If locomotion is compulsory, the misfortune of the necessity may be lessened by having a stout piece of woolen flannel bound tightly round the abdomen, so as to be doubled in front and kept well in its place. In the practice of many years, we have never failed to notice a gratifying result to follow these observations.—*Hall's Journal of Health.*

GEOLOGICAL MAP OF CANADA.—This map, which includes also a portion of the United States as far south as Kansas and Northern Virginia, is noticed at some length by *Silliman's Journal*, which has received one of the few colored copies yet issued. It is on a scale of 25 miles to an inch. There are 31 geological divisions, indicated by as many different colors. It is spoken of as a very complete and valuable work.

THE *People's Tribune*, published by Conrad Weigand, at Gold Hill, Nevada, has been received. It has certainly a most extensive aim, being "devoted to the betterment of all things, to the defense of right, and to the people." As its subscription list and advertising cannot maintain it, the editor frankly says, it solicits for its support private contributions from those who desire it to be continued.

THE FENIAN RAID on Canada seems to have come to a speedy end. There were one or two skirmishes and then the invaders appear to have been satisfied and to have retired within our lines. Numerous arrests have been made by U. S. officers. Many Fenian leaders, it is fair to state, have expressed themselves as strongly against the movement, which appears to have been instituted by a few restless spirits.

A SMALL CRAFT.—The telegraph gives information that the little steamer City of Ragusa, left Liverpool for New York on the 31st of May. She is only twenty one feet long, carries a crew of two men besides a Newfoundland dog, and provisions for three months.

Boyhood Days.

We were brought up in the city. Although permitted, after arriving at a certain age, to wander among the fields and fragrant woods adjacent to a country town, and to blister our hands and to brown our faces in out-of-doors work, yet our early days were consumed in the perusal of useful books in the intervals between our games of "tag" and marbles.

The consequence was that we were good boys. Never did we rob a melon patch or a hen's nest. The taste of the raw egg was long unknown to our lips, and the cider barrel never yielded its sweet contents, long drawn out through a straw, to our youthful months. Whatever faults we may have possessed, we were spared these temptations.

Looking back at these days, we feel thankful that we were not like the man of the *Rural New-Yorker*, who is represented by the middle figure in the adjoining cut, as he once was. He has undoubtedly improved since then, as the picture, drawn by him, is a tacit confession, and as the making of a confession is a mark of improvement. When he gets older and has learned to spell, he will, no doubt, become quite a man.

SUM INTERESTING SUCK-EM-STANCES OF MY AIRLY LIFE.

HOW TO CHOOSE BLACK SILK.—As this is a point upon which most ladies possess little or no information, the following correct test if observed, will be found advantageous: "When a woman is about to choose black silk, it is well to pull a thread out of the 'tram' or filling. She must try the strength of the thread. If it breaks easily, the examination has gone far enough; it is wisdom to look further. We will suppose the thread has been tried, and that it indicates some backbone. Then it is necessary, if the woman is right brave, and dares to do such a thing with a handsome clerk's eyes bearing down upon her like a privateer upon a poor little merchantman, to seize the silk by the corner and rub it just as the washerwoman would do when she intends to remove a stain. If this awful ordeal can be performed to perfection—remember some muscle must be brought to play—the silk is honest and legitimate. If it is heavy with dye, if held up to the light, slight traces of disaster may be discerned."—*N. Y. Telegram.*

TO WASH SILK.—Half a pint of gin, four ounces of soft soap, and two ounces of honey well shaken. Wet a sponge with this mixture, and rub the silk, which should be spread upon a table. Then wash it through two waters, in which put two or three spoonfuls of ox gall, which will brighten the colors and prevent them running. Do not wring the silk, but hang it up to dry, and while damp iron it. The lady who furnishes this recipe says she has washed a green silk dress by it, and it looks as good as new.

VINEGAR IN COOKERY.—All kinds of poultry and meats can be much more quickly cooked by adding to the water in which they are boiled about one-eighth part of vinegar. By the use of this there will be considerable saving of fuel and shortening of time. Its action is very beneficial on old tough meats rendering them quite tender; and fowls will also lose their bad taste and odor if cooked this way, and if no more vinegar is added than we have indicated, there will be no taste of vinegar acquired.

A NOVEL METHOD OF REFORM is to be tried as an experiment on a large scale in Boston. About one hundred and sixty night-walkers were arrested recently in the streets at night. Their conditions of life were investigated, and it is found that one hundred of them are poor girls, who would be glad of the opportunity of decent employment. It is intended to place them under some wholesome restraint, the Court imposing some sentence upon each, but suspending its execution until the result of the experiment in each case is ascertained. Homes will be found or provided for those who have none; those that have homes will be sent to them. Work and means of support will be supplied, and the entire police force will assist in their supervision. Two Catholic clergymen lend their personal efforts to the undertaking, and it is hoped that the report which is to be made in Court in the latter part of June, will justify, in a majority of instances, a revocation of the sentences.—*San Francisco Chronicle.*

EXECUTIONS IN LONDON IN THE OLD TIMES.—People went to the hangings as to a festival. The vulgar drank and swore worse than our army in Flanders, while the "quality" made a picnic of it. The longer the whole ceremony—the addresses to the people, the leave-taking with kinsfolk and sweethearts—the better the spectators were pleased. The finale was as lugubrious as imagination can conceive. The ropes round the victims' necks were fastened to the beams, the carts were lazily driven away from under them, and the hangman rode off without giving himself any further trouble. Then the friends, familiars, or relatives of the hanging men rushed to the suspended bodies, and began pulling them by the legs, or dealing them heavy blows in the stomach, in order to bring their sufferings to an end. The Newgate chaplain, meanwhile, took his ham and liquor in the first friendly carriage into which he was invited; and at night the whole affair was talked over everywhere in London and the suburbs. Men in the last century seemed to go as naturally to Tyburn as Irish Colonels to Gretna Green, and young ladies of St. James' talked about the last execution with the strolling player, who was their dancing-master, or the deserter from Dunkirk, who taught them French.—*Athenæum.*

EXTRACTING WHEEL GREASE, ETC.—I have cleaned wheel-grease from a nice silk thus: Laying the silk on a clean sheet folded to eight thicknesses, I rubbed the greased part with a soft cloth dipped in lard, moving the silk to a new spot frequently. After a time the wheel-grease all went through, leaving only clean lard. This was then cleaned out in the same way, by rubbing it with some nice soap and alcohol, using a clean cloth to rub with, and frequently changing to a new spot on the under-lying sheet. The silk was then laid on a clean cloth, and rubbed dry with a soft cloth. A friend cleaned white Canton crape in this way, and you cannot find a place where it was greased.—*S. M. Healy.*

STAINS.—All clothes subject to be stained, such as table linen, napkins, children's clothes, towels. etc., ought to be examined before being put into any wash mixture of soap suds, as these render the stain permanent. Many stains will yield to good washing in pure, soft, warm water. Alcohol will remove almost any discoloration. Almost any stain or iron rust, or mildew, may be removed by dipping in a moderately strong solution of nitrate acid, then covered with salt and kept in the sun. This may require to be repeated many times, but with us it has never failed.

New Books.

LOTHAIR, a novel, by the Rt. Hon. B. Disraeli. Published by D. Appleton, New York, 1870; for sale by A. L. Bancroft & Co., S. F. Price, $1.

The mere announcement of the fact that *Lothair* was written by an ex-Premier of England, and treats only of the nobility of that country, will be sufficient to induce many to read the book; and the statement that it is published for a political purpose will, in these times, when every one is posted, to a certain extent, on the political struggles of Great Britain, by no means diminish the eagerness to peruse it. The publication is said to have produced quite a sensation in England. It treats freely of Fenian meetings, Popish intrigues, and Red Republican conspiracies. The hero, Lothair, is one of the wealthiest and highest born of the aristocracy, to win whom to their respective beliefs the various parties earnestly contend, and the main plot hangs on the conflict between the Church of Rome and its enemies. Every important character, except an aristocratic Southern planter, is of noble rank, and we have to deal with both sexes. But we are disappointed in the book. It is interesting in its pictures of life and character, and often very well written, but still we tire in the perusal. It may be because we have expected too much, judging from Disraeli's former works. However, it is a book which must be read by every one who pretends to keep posted on the publications of the day, and each person must judge of it for himself.

A CATALOGUE OF THE PLANTS GROWING IN THE VICINITY OF SAN FRANCISCO. By Henry N. Bolander. (late State Botanist.) A. Roman & Co., publishers, San Francisco, 1870.

This most valuable contribution to the scientific libraries of the coast, appears in a very handsome and well arranged form. It contains the Latin and English names and the natural habitst of nearly all the phænogamous and cryptogamous plants found about a hundred miles north and south of San Francisco, and as far east as Mount Diablo. Some plants are omitted (especially the shrubby oaks) since it was impossible to determine their proper specific names. The two important families, the fungi and algæ, have been entirely omitted, not having been made the subject of investigation and study on this coast by any one as yet. The ferns, mosses, liverworts and lichens were studied by the very best authorities in America.

A NEW breed of cats is reported in the German papers. Some months ago a Lithuanian lynx escaped from a traveling menagerie at Altona, and $20 reward was offered for its capture; but in vain. Not long ago a sentinel at Kiel observed a strange looking cat-like animal coming out of the mouth of a large cannon on the ramparts, and after a short time returning with a duck in its jaws. The man got assistance, a net was spread over the muzzle of the gun, and the missing lynx was recaptured, together with a domestic cat and a litter of three young ones. These curious kittens have been transferred to the botanical gardens at Hamburg, where they have been visited by many naturalists. The Directors of the Zoölogical Garden in Paris have already offered 5,000 francs ($1,000) for one single specimen.—*Bulletin.*

EUROPE contains 70,718 miles of railway, composed of 150,000,000 cwt. of iron rails, on which 400,000 passenger carriages and 600,000 baggage cars are dragged by 18,000 locomotives, over 52,000 bridges and through 34 miles of tunnels, at a cost of $60,000,000 per annum, with a consumption of 4,000,000 tons of coal.

THE preparations at Vienna for an International Art Exhibition are nearly completed; 800 pictures have already been received. Nearly one-half of these are contributed by Viennese artists. Paris sends 88; Dusseldorf, 86; Munich, 65; Weimar, 10; Venice, 8. Belgium, strangely enough, has sent only four.

BREAK IN THE FRENCH CABLE.—Communication by the French Cable suddenly ceased on the evening of the 26th ult., between Duxbury and St. Pierre. A vessel was to leave immediately to repair it.

THE Crown Prince of Austria is called a "dull, indolent, good-natured lad, who cares for nothing but dancing and music."

THE Cunard Steamship Company have purchased a pier of the Dry Dock Company, in Hoboken, and the buildings of the Cunard Company will be removed, and the vessels sail from the new dock after the first of July.

A Civil Engineer

Of thirteen years standing and highest Eastern, South American and Pacific coast references, tenders his services at moderate rates. Can present attractive inducements to capitalists. Address W. S. C., Box 1,036, San Francisco. 20v20-1m

☞Maravilla Cocoa.—*For Breakfast.*—The *Globe* says: "Various importers and manufacturers have attempted to attain a reputation for their prepared Cocoas, but we doubt whether any thorough success has been achieved until Messrs. Taylor Brothers discovered the extraordinary qualities of 'Maravilla' Cocoa. Adapting their perfect system of preparation to this finest of all species of the Theobroma they have produced an article which supersedes every other Cocoa in the market. Entire solubility, a delicate aroma, and a rare concentration of the purest elements of nutrition, distinguish the Maravilla Cocoa above all others. For homœpaths and invalids we could not recommend a more agreeable or valuable beverage." Sold in packets only by all Grocers, of whom also may be had Taylor Brothers Original Homœopathic Cocoa and Soluble Chocolate. Steam Mills—Brick Lane, London. 5v20-1y

To Miners, Millmen and Metallurgists. Kustel's new work on the Concentration of all kinds of Ores, and the Chlorination Process, for Gold-bearing Sulphurets, Arseniurets, and Gold and Silver Ores generally, is the best and most complete work issued. It contains 120 diagrams, illustrating machinery, etc., which alone are of the greatest value. Price, $7.50, postage paid. Published by Dewey & Co., publishers of the Scientific Press, San Francisco.

Useless Expense Saved.—One of the benefits to inventors arising from honest and reliable agents is illustrated by the following correspondence:

Chico, March 24th, 1870.

Messrs. Dewey & Co.:—Yours of the 22d came to hand. We are under obligation for the information you have given us, and are satisfied without further inquiry. Your charges for examination are moderate—much less than we expected; and we will endeavor to patronize you again, hoping we will be more successful next time. We will also ask your opinion before applying for a patent. Please deduct the amount of subscription for your paper for one year, and remit the balance by express.

Respectfully, J. W. C & C. W. C.

Business Fortunes are often made easily, quickly and legitimately by Patent Rights. We advise both sellers and purchasers to patronize reliable agents only. Webster & Co., patent brokers, No. 314 Bush street, San Francisco, are one of the most honest, reliable firms in the United States. *

We call attention to the new portable gas burner—the only one that can be regulated to any size, flame, and burn without smoke or smell. Equal to any gas at one-fourth the cost. P. J. Philips & Co., 650 Market street, have county rights for sale for this valuable invention; also lamps for sale. No one should be without them who wants a good, cheap and safe light. 21v20-4w

Treatment of Rebellious Silver Ores, by Charles H. Aaron—a pamphlet of eight pages of concise reading, of practical value to parties interested in the subject. Printed and sold by Dewey & Co., at this office, for 25 cents, post paid.

To Farmers.—Stevens & Bro's Egg Boxes, holding 30 dozen, supplied free of charge, by John Gray & Co., No. 210 Clay street, San Francisco, to all customers. The eggs are kept cool and free from moisture and mould, are in no danger of being broken, and require no recounting. 20v20-3m

Photography.—For Cabinet Photographs, or Enameled Cards, of the very best quality, you must go to the NEW YORK GALLERY, Nos. 25 and 27 Third street, San Francisco. Every picture warranted to give satisfaction.
10v18 5m B. F. Howland.

At the age of forty or thereabouts the eyesight requires the aid of magnifying glasses. Muller's Brazilian spectacles are acknowledged to be the best in use. *

A Valuable Book for Inventors and Artisans.—Dewey & Co., publishers of the Scientific Press and Patent Agents, have just issued a neat little volume of over five hundred well executed cuts of the principal mechanical movements known. These useful representations of the various appliances of power are printed side by side with explanatory notes, which makes the subject clear to every reader. Such a book should be in the hands of every mechanic, and form part of every public school library. It is a handy book, and cheap enough for every farm, shop and factory. Sent to any address from the Scientific Press office, postpaid, for $1.—*New Age.*

Attention to Mining Companies of Copper and Galena Ores.—A mining engineer and assayer thoroughly acquainted with practical smelting of lead and copper ores, and competent to put up all kinds of furnaces, wishes employment. References given. Please address C. T. MOHRIG, care of Schultz, Fischer & Mohrig, No. 10 Stevenson street, near First, San Francisco. 23v20-1m

TARRANT'S SELTZER APERIENT.

Dyspepsia Met and Conquered.—Pain has its uses. It indicates the seat of disease and its nature. If the locality, progress and intensity of a disorder were not manifested by the torture it occasions, the victim would be surprised by death before he was conscious of danger. The indescribable tortures which accompany Dyspepsia, preclude all doubt as to the character of the malady. Combat the enemy promptly with Tarrant's Effervescent Seltzer Aperient. This pleasant specific meets the disease at all points—in the weakened stomach, the torpid liver, the constipated bowels, the shattered nerves—and by restoring all these organs to their natural condition, effects a radical cure.

SOLD BY ALL DRUGGISTS. 23v20

Illustrate your Inventions

In the Scientific Press,

An illustrated journal of Mining, Farming, Mechanic Arts and Industries on the Pacific Coast. It costs no more for a superior engraving by our experienced artists than is usually charged for a less perfect picture. If you wish to introduce a new invention properly before the public, the first steps in so doing are important ones. A full description and correct representation in the Press will go further and prove more quickly effective than any other means.

The fact that an illustration is admitted into our columns, guarantees the invention important consideration in the minds of thousands of the most intelligent readers—at home and abroad—who would not notice it so favorably or so thoroughly, if at all, when presented through an unreliable medium or indifferent source.

The model of an invention sent to us is sufficient for making a good engraving. Sometimes a photographic view is sufficient; but it is always best accompanied with drawings or a copy of the patent. A first-class illustration has proved to be one of the best and cheapest means of obtaining purchasers for a good machine or a valuable patent.

Cuts ordered for illustration are the property of the inventor who pays for them, and can generally be used for circulars, pamphlets, books, or other newspapers. The engravings to be seen in each issue of the Scientific Press are a fair sample of the work of the artists who can always be found in our office.

They are the cheapest and best in the market. Manufactory on Twelfth street, bet. C and D, Sacramento. Caveat filed Aug. 9, 1869. [15v20] G. B. DEAN.

Valuable Ranch For Sale.

NEAR HEALDSBURG.—In the fine valley of Russian River three and one-half miles south of Healdsburg, on the west side of the river, is now offered for sale a splendid farm of 250 acres of land (minus eight by twelve rods occupied by a good school house), 100 of which is of the richest of Russian River bottom, eighty acres of which is now in small grain, not surpassed by any in the State, five acres in bearing orchard of the choicest selections, fifteen acres plowed for corn, and the remaining 160 acres is rich, yet rolling timbered land, five acres vineyard of choice selection. The Dwelling has ten rooms, not yet finished, and supplied by a good spring of excellent water, and cost above $12,000. The barns and outhouses are in excellent condition. The title is "Fitch Grant," which is undisputed. The entire farm is inclosed, about half with a picket and half with a rail fence, both in good condition. The farming utensils which are offered with or in the sale of the farm, are as follows: Five plows, two harrows, two cultivators, one Buckeye reaper; also twenty head of hogs. There are 200 redwood trees within about five miles of the premises, and wood enough to supply all the demands of the place. It is well known by all parties who have resided for any length of time on this coast, that the climate of Russian River Valley is lovely, healthy and not surpassed by that of any other place in the United States.

The reason for selling is, that the owner is getting too old to cultivate a farm, and wishes to close up his business and live more retired. The place is a rare bargain at the price asked for it.

For further particulars, apply to McLean & Hardy, Real Estate Agents, No. 338 Montgomery street, southeast corner of California street, San Francisco. 11v20

CANVASSERS WANTED for a New Book: THE CHEMICAL FORCES—HEAT, LIGHT, ELECTRICITY; Their Application to Important Modern Inventions and Scientific Discovery, by Thomas Ruggles Pynchon, Professor of Chemistry and the Natural Sciences, Beautifully Illustrated by 259 Engravings and by many entertaining experiments. The work is elegantly printed. All experienced agents should send for descriptive circular and terms. F. DEWING & CO., 542 California street, San Francisco, 19v20-5w

GIANT CEMENT.
GIANT CEMENT.

A most extraordinary and universally needed article for mending Furniture, Crockery, Glassware, Marble, Meerschaum Pipes, Ornaments, etc.; also splicing Leather Belting and patching Boots and Shoes. This Cement possesses extraordinary merit, and is in every way a first-class article. Every can is its own testimonial. Also, Miners' Rubber Cement, for mending Rubber Boots, Shoes, Belting, Coats, and Hose without stitching! Easily applied, never failing, and perfectly waterproof. Both Cements are put up in tin cans only, with full directions. Take no other. Giant Cement and Miners' Rubber Cement are kept by Druggists and Dealers throughout the country. Country Dealers can be supplied by ordering from any house here or in Sacramento with whom they deal, or by sending direct to us. Send for Agents' Circulars and Price List, to Giant Cement Manufacturing Co., 419 Washington street, San Francisco.

MINERS' RUBBER CEMENT.
MINERS' RUBBER CEMENT.

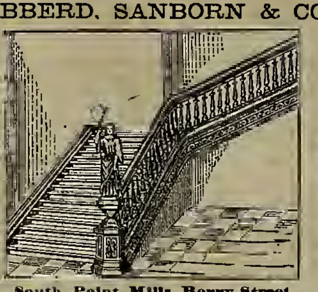
STAIR



BUILDERS.

South Point Mills, Berry Street,
Between Third and Fourth, San Francisco. Orders from the country promptly attended to. All kinds of Stair Material furnished to order. Wood and Ivory Turners. Billiard Balls and Ten Pins. Fancy Newels and Balusters.

Greatest Discovery Ever Made.

MR. J. W. MAC, while a resident in New Zealand, was so afflicted with the RHEUMATISM, that for years he was completely crippled and unable to attend to business. The symptoms were of the worst type—knees painful and swollen, with sinews contracted; shoulder, arm and hand rendered useless, and accompanied with continued excruciating pain. While in this state of suffering, he got acquainted with a native of the country, who applied to the parts affected a composition spread on coarse canvas, the properties of which were so wonderful that in a short time all the pain left him, the swelling disappeared, his sinews relieved, and he was able to resume his usual avocations. So effectual has been the remedy, that to this day he has enjoyed perfect health, without the slightest return of his former complaint. Knowing the great blessing such a remedy would be to those afflicted with this painful disease, he with great difficulty and expense obtained the secret of preparing the Plaster; and during the many years MR. MAC has applied these Plasters in New Zealand, Tasmania, New South Wales, and this city, their effect has been marvelous, giving to the most painful and long-standing cases sure and certain relief. The most incredulous will be convinced by referring to these persons: B. W. Owens, 405 Front street; F. B. Alderson, Traveling Agent for Dewey & Co., 414 Clay street; James Flynn, 519 Mission street; Michael Gorman, No. 6 Front street; Mrs. W. S Wright—late of Gilmore House—518 Folsom street, now agent at Virginia City; E. Shenley, corner Montgomery and Filbert streets; W. M. McLeod, Depository merican Tract Society, 557 Market street, and a host of others, who all bear testimony to the unparalleled healing powers of J. W. MAC'S (rightly termed Magic) Plasters, for the cure of Rheumatism, Gout, Weak Loins, Tender Feet and Neuralgia. J. W. MAC may be consulted at his office, rooms Nos. 34, 35 and 36, 128 Kearny street, San Francisco, between the hours of 9 to 12 A. M., 2 to 4 P. M. and 7 to 9 P. M.

18v20-3m.

The Latest, Cheapest, and Most Durable.

CRANDALL'S

PATENT SPRING BED.

This invaluable Spiral Spring Bed combines all the good without any of the bad features of the common spring mattrass. It consists of a framework of springs resting on a bed of stronger springs, thus giving it nearly double the elasticity of any other bed. The springs are self-supporting, each pair being independent of the others, and consequently the tendency to sag or incline toward the middle is avoided. Unlike other spring beds, they require no upholstering, and, of course, afford no harbor for fleas or dust. The medical faculty have pronounced it the best Bed in use. It commends itself to those who have examined and used it. They invariably pronounce Crandall's Patent the best Spring Bed ever offered to the public.

These Beds are on exhibition and for sale at the Cabinet Warerooms of

JOHNSON & BEST,

No. 413 PINE STREET, RUSS BLOCK,
Between Montgomery and Kearny. Also at
639 Market Street, near New Montgomery.

Beds guaranteed to give satisfaction
Or the money will be refunded.

USE

DR. S. GIRARD SMITH'S

ARAMIRACULAS

—FOR—

RHEUMATISM, GOUT AND NEURALGIA

CURES GUARANTEED.

Has cured Thousands. Has never been known
One bottle will relieve you.

OFFICE, No. 121 POST STREET

TRADE

MARK.

Agents Wanted in every City and Town.—Terms Liberal.

Dr. S. Girard Smith, 621 *Kearny street.*—Dear Sir It would be hard for me to say how much I thank you for the benefit your ARAMIRACULAS has conferred on me in curing my RHEUMATISM. I was confined to my bed when I first commenced to take your medicine, and after using ONE BOTTLE I am now able to work as well as before. If you know anything about having that afflictive complaint, you must know how good it is to be cured. I will state to those who may not believe in your medicine, that they can be convinced by referring them to me. Very respectfully, yours,

ENON HARRIS,
Everard's Auction Rooms, 527 Kearny street.

Statement of an old and well-known Physician who has practiced extensively in Europe and America.

We must admit that the many systems of medicine by which we have attempted to heal the human body, and rid it of disease, from the science of ALLOPATHY down to HYDROPATHY, how little they have succeeded, time has abundantly shown by their number of failures. In the cure of RHEUMATISM, GOUT and NEURALGIA, Dr. S. Girard Smith has laid aside the old way and adopted a system, so simple, that I must admit, is so natural and direct, that it recommends itself to all who are suffering with the above diseases. And it challenges and defies all the old methods of treatment. Although I have been educated through a regular course, and graduated in Europe, I must acknowledge the right, and also give due credit for personal benefit received by the new system as practiced by DR. S. GIRARD SMITH, which induces me to bear this testimony to its merits, for the benefit of suffering humanity.

A. M. HOFFMAN, M. D.,
11v20-3m New Orleans.

Ayer's Sarsaparilla,

FOR PURIFYING THE BLOOD.

The reputation this excellent medicine enjoys, is derived from its cures, many of which are truly marvellous. Inveterate cases of Scrofulous disease, where the system seemed saturated with corruption, have been purified and cured by it. Scrofulous affections and disorders, which were aggravated by the scrofulous contamination until they were painfully afflicting, have been radically cured in such great numbers in almost every section of the country, that the public scarcely need to be informed of its virtues or uses.

Scrofulous poison is one of the most destructive enemies of our race. Often, this unseen and unfelt tenant of the organism undermines the constitution, and invites the attack of enfeebling or fatal diseases, without exciting a suspicion of its presence. Again, it seems to breed infection throughout the body, and then, on some favorable occasion, rapidly develop into one or other of its hideous forms, either on the surface or among the vitals. In the latter, tubercles may be suddenly deposited in the lungs or heart, or tumors formed in the liver, or it shows its presence by eruptions on the skin, or foul ulcerations on some part of the body. Hence the occasional use of a bottle of this *Sarsaparilla* is advisable, even when no active symptoms of disease appear. Persons afflicted with the following complaints generally find immediate relief, and, at length, cure, by the use of this ***SARSAPARILLA: St. Anthony's Fire, Rose or Erysipelas, Tetter, Salt Rheum, Scald Head, Ringworm, Sore Eyes, Sore Ears***, and other eruptions or visible forms of ***Scrofulous*** disease. Also in the more concealed forms, as ***Dyspepsia, Dropsy, Heart Disease, Fits, Epilepsy, Neuralgia***, and the various ***Ulcerous*** affections of the muscular and nervous systems.

Syphilis or ***Venereal*** and ***Mercurial Diseases*** are cured by it, though a long time is required for subduing these obstinate maladies by any medicine. But long continued use of this medicine will cure the complaint. ***Leucorrhœa*** or ***Whites, Uterine Ulcerations***, and ***Female Diseases***, are commonly soon relieved and ultimately cured by its purifying and invigorating effect. Minute Directions for each case are found in our Almanac, supplied gratis. ***Rheumatism*** and ***Gout***, when caused by accumulations of extraneous matters in the blood, yield quickly to it, as also ***Liver Complaints, Torpidity, Congestion*** or ***Inflammation*** of the ***Liver***, and ***Jaundice***, when arising, as they often do, from the rankling poisons in the blood. This ***SARSAPARILLA*** is a great restorer for the strength and vigor of the system. Those who are ***Languid*** and ***Listless, Despondent, Sleepless***, and troubled with ***Nervous Apprehensions*** or ***Fears***, or any of the affections symptomatic of ***Weakness***, will find immediate relief and convincing evidence of its restorative power upon trial.

Machinery.

THE WILSON
Patent Steam Stamp Mill.

This extraordinary Mill, now so justly popular in the East, is now offered to the miners of the Pacific Coast. Having been in operation now for about eighteen months, the Company feel confident that the

WILSON STEAM STAMP MILL,

For Durability, Efficiency,

AND ECONOMY OF WORKING,

HAS NO EQUAL.

The Wilson Steam Stamp Mill is the only Steam Mill that has had the severe ordeal of practical working, and proved itself eminently successful. It is now in operation in several of the Eastern States and Territories, and gaining an envious popularity. The whole machine is so simple as to be readily understood by the most ordinary minds. In fact, its simplicity is its durability. The expense of crushing rock or cement with this Mill is less than one-half the expense of any other Stamp Mill, and less than one-half the cost. For further particulars inquire of

A. BICKNELL, Agent,
Nevada City, California,

Or of THE WILSON STEAM STAMP MILL CO., 326 Walnut street, Philadelphia, Pa.

Notice.—All persons are hereby warned not to manufacture or use any Steam Stamp Mills that are an infringement on the Wilson Patents, as they will be prosecuted to the utmost rigor of the law.

F. R. WILSON,
20v19-tf Supt. W. P. S. S. M. Co., Philadelphia.

VARNEY'S
PATENT AMALGAMATOR

These Machines Stand Unrivaled.

For rapidly pulverizing and amalgamating ores, they have no equal. No effort has been, or will be, spared to have them constructed in the most perfect manner, and of the great number now in operation, not one has ever required repairs. The constant and increasing demand for them is sufficient evidence of their merits.

They are constructed so as to apply steam directly into the pulp, or with steam bottoms, as desired.

This Amalgamator Operates as Follows:

The pan being filled, the motion of the muller forces the pulp to the center, where it is drawn down through the aperture and between the grinding surfaces. Thence it is thrown to the periphery into the quicksilver. The curved plates again draw it to the center, where it passes down, and to the circumference as before. Thus it is constantly passing in a regular flow between the grinding surfaces and into the quicksilver, until the ore is reduced to an impalpable powder, and the metal amalgamated.

Settlers made on the same principle excel all others.—They bring the pulp so constantly and perfectly in contact with quicksilver, that the particles are rapidly and completely absorbed.

Mill men are invited to examine these pans and settlers for themselves, at the office, **229** Fremont street,
1v1 San Francisco.

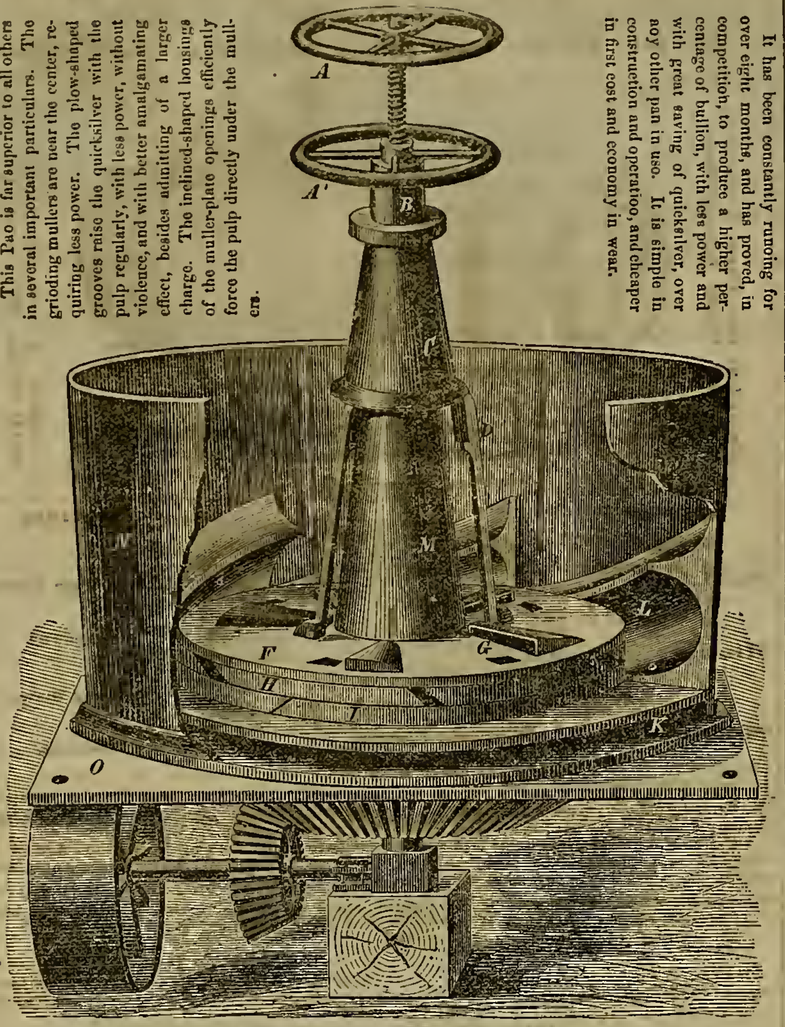
TO MILLMEN.

FOR SALE CHEAP.—A 10-stamp mill complete; engine about 35 horse-power; cylinder 12-inch bore and 30-inch stroke; boiler 16 feet long and 48 inch diameter; weight of stamps complete, 650 pounds. The whole is as good as new; has only been running four months. Will sell either engine or battery separate, and deliver it on the railroad at Auburn if required. For particulars apply to W NAGEL, 702 Bush street, San Francisco, or to MOUNTAIN CO., Forest Hill, Placer county. 16v20-3m

STEVENSON'S PATENT MOULD BOARD AMALGAMATING PAN.

This Pan is far superior to all others in several important particulars. The grinding mullers are near the center, requiring less power. The plow-shaped grooves raise the quicksilver with the pulp regularly, with less power, without violence, and with better amalgamating effect, besides admitting of a larger charge. The inclined-shaped housings of the muller-plate openings efficiently force the pulp directly under the mullers.

It has been constantly running for over eight months, and has proved, in competition, to produce a higher percentage of bullion, with less power and with great saving of quicksilver, over any other pan in use. It is simple in construction and operation, and cheaper in first cost and economy in wear.



Manufactured at the Golden State Iron Works (Co-operative). 19 First street, S. F.,

Where it can be examined and further particulars be learned; or persons may apply to the inventor and patentee, Mr. C. C. STEVENSON, at the Douglas Mine, Gold Hill, State of Nevada, where the Pans have long been in constant operation. 15v20-1mr,1amtf

Important to Assayers.

Crucibles.

The Patent Plumbago Crucible Co.

Manufacturers of all kinds of

Melting Pots, Portable Furnaces,
CRUCIBLES, and other fire-standing Goods,
Battersea Works, London.

THE MORGAN PATENT CRUCIBLES have uniform quality, never crack, withstand the greatest heat without danger; heats more rapidly than any other; change of temperature has no effect on them; stand on the average forty to fifty pourings.

CERTIFICATES:

United States Branch Mint, San Francisco, Cal., March 12, 1869—Messrs. A. S. Hallidie & Co., Agents Morgan Crucible:—I have carefully tested the Morgan Patent Plumbago Crucibles purchased from you for the U. S. B. Mint, and cheerfully certify to their superiority and economy over all other Crucibles used by and under me. They are fully what you represent them, and I shall continue to use them in preference to any other. J. M. ECKFELDT, Melter and Refiner, U. S. B. Mint.

Eagle Brass Foundry, 206 Fremont street, San Francisco 12th March, 1869—Messrs. A. S. Hallidie & Co., 519 Front street—Gentlemen:—We have used and tested the Morgan Patent Plumbago Crucible, for which you are agents, and pronounce them superior to and cheaper than any Crucible used by us heretofore. GREENBERG & MOORE.

Messrs. A. S. Hallidie & Co.:—We have thoroughly and severely tested in every way the Morgan Patent Plumbago Crucible obtained by us from you, and find them superior to any we have yet tried, although we have used every pot obtainable in this market, we have none equal to the above, and concede your claims for them. We think they will average 45 pourings of brass. GALLAGHER, WEED & CO., California Brass Works, 125 Front street, San Francisco.

Assay Office of H. Harris, Silver City, Nevada, April 24, 1869—Messrs A. S. Hallidie & Co.—Gents.:—I received from you three Crucibles of the Morgan make, which I have used since their arrival, and tested by constant use. Since 1847, when in the New Orleans Mint, I have always preferred the Crucible of Dixon's make over Adus, Gautier, and Taunton, Mass. Yours I find to be not alone of more finished make, but to stand double or treble the work of Dixon's Crucibles. The No. 12—the smallest sent—has stood so far 32 meltings, and is as good and sound as when received. Your Crucibles do not scale off like others; and as they are forty per cent. cheaper, I do not see why they should not be preferred by all assayers on account of durability and cheapness. Yours respectfully, H. HARRIS.

On hand and for sale by the Agents,

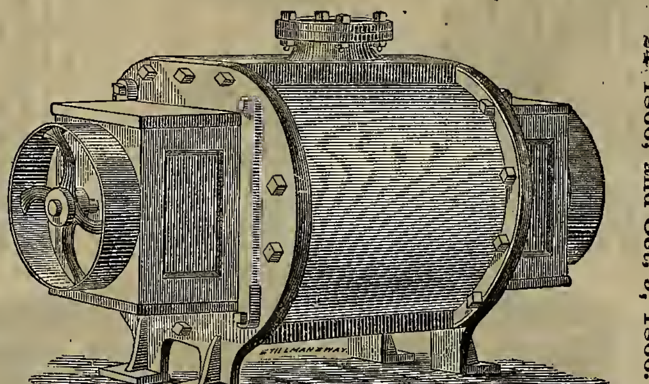
ROOT'S PATENT FORCE BLAST ROTARY BLOWER.

MANUFACTURED BY KEEP & BARGION,

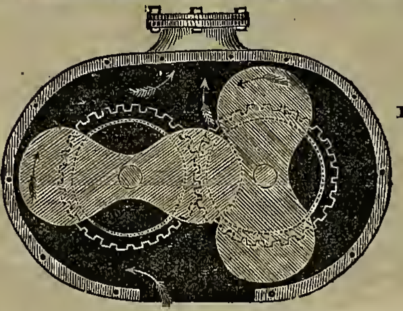
At the Globe Iron Works, Stockton, California.

Awarded the First Premium at the Paris Exposition.



Patented Nov. 1st, 1864; July 24, 1866; and Oct. 9, 1866.

ADAPTED FOR Smelting, Foundry, Mining and Steamships.



REQUIRES Fifty Per Cent. LESS POWER **Than any Blower** Now in use.

One of these Blowers may be seen on exhibition at W. T. Garratt's Brass Foundry, corner of Mission and Fremont streets. They are also in use at the Almaden Quicksilver Mine; Gridley's Foundry, Gold Hill, Nevada; Ætna Iron Works, San Francisco, and many other places.

Caution.—Purchasers will find it to their advantage to apply direct to the Stockton Agency. as certain parties, not authorized to manufacture the Blower, have put in the market machines of inferior construction, which do not answer all the requirements of the genuine article.

Quartz, Saw and Grist Mill Irons, Steam Engines, Horse Powers, High and Low Pressure Steam Engines, Steamboats and Propellers, made at short notice.

For circulars and further information, address

4v16-3m **Globe Iron Works, Stockton, Cal.**

WIESTER & CO.,

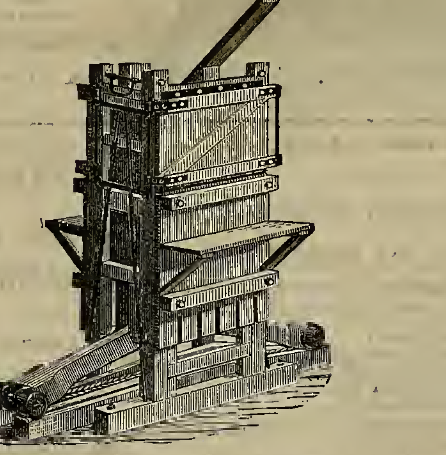
PATENT BROKERS,

No. 314 Bush Street, San Francisco.

PATENTS BOUGHT AND SOLD ON COMMISSION.

For the benefit of those who live at a distance from the city, we give below a brief description of a few of the valuable Patents which we have in our office. It may be well to state here that no Patent is received by us for negotiation until it is first endorsed by reliable experts, to whom each is subjected for acceptance or rejection. We treat all patents alike, recommending only where true merit is found in the invention.

EAGLE HAY PRESS.



PATENTED JANUARY 10, 1865, AND JULY 24, 1866.

Here is an invention that we take pleasure in recommending. There is probably no farming implement more perfect in its line than this Press. It has advantages over any and all other Presses now in use. It costs only $300 and weighs only 1,600 pounds, which is $100 lower in price and 1,500 pounds less in weight than any other good Press on the Pacific coast Three men and a pair of horses with this Press can bale from ten to fifteen tons per day, each bale weighing from 250 to 350 pounds. The power is applied by means of two levers acting on the principle of the toggle-joint, and the pressure acquired as they approach a vertical position can scarcely be estimated. On account of the great power obtained in this Press, it is well adapted to baleing hides, rags, wool, cotton, etc. They can be built at any blacksmith and wagon shop. They cost to manufacture $150 less than any other first-class Press in the United States. A large number have already been sold, and all are giving good satisfaction. The Right to California, Oregon and Nevada will be sold in States or counties. We keep on hand well built sample Presses to furnish to parties buying territory. Any information in regard to the Press or territory can be obtained by addressing WIESTER & CO., 314 Bush street, San Francisco.

RYAN'S NEW METHOD OF MAKING WHEELS.

To make indestructible iron wheels with little labor and at a small cost is the object of this invention. The hub and spokes are all made out of a single piece of iron shaped much like that used for making a horseshoe. The great amount of labor and expense heretofore required in making wrought-iron wheels is obviated by this novel mode of construction. There probably never has been a wheel made that is so durable as the Ryan Wheel, and yet the method of construction is so simple that it can be made by any ordinary mechanic in a common blacksmith shop. All territory west of the Rocky Mountains for sale in States or counties. Thomas Ryan, of Scott's Bar, California, is the inventor. Sample wheels, and the iron from which they are made, can be seen at our office, 314 Bush street, San Francisco

Mechanics' Institute—Annual Report.

The regular annual meeting of the Mechanics' Institute, and the first quarterly meeting, under the new organization, was held on Thursday evening last. After some preliminary business, it was voted that hereafter the regular weekly meetings of the Institute be held on Saturday, instead of Thursday evenings as heretofore.

The President, Mr. Hallidie, submitted his annual report, in which he gave a brief review of the operations of the Institute for the past year, made a passing reference to the present condition of the State and city, their relations to the Orient, etc.; regretted the failure of the late Legislature to locate in this city the three Colleges of Mechanic Arts, Civil Engineering and Mining, and then passed to a statement of the financial condition of the Institute, from which it appears that the Library now contains 15,724 books, of which number over 3,000 have been added the past year.

The receipts for the past 16 months—including Fair receipts—have been $41,146; expenditures, $40,950, of which amount $10,000 have been paid on account of the mortgage on the building, and $5,172 for books.

The assets of the Institute (valuing the lot and building at $115,000) are set down at $153,461; liabilities, $41,234—net assets over liabilities, $112,227; showing a gain over the amount of assets reported in the last annual report of $22,853.

Annual Election.

The first annual election of the Institute, under the new organization, took place on Monday last, and resulted in the choice of the following gentlemen as Trustees: A. S. Hallidie, H. L. Davis, Geo. Pardy, Geo. Spaulding, David Kerr, Chas. R. Steiger, Howard Chapman, J. O. Hanscom, Robert Ewing, James Moffit, B. P. Bruner, Samuel H. Harmon, Henry C. Kibbe and John Roach. The election was for fourteen Trustees, seven for one year and seven for two. The gentlemen elected will draw lots for the long and short terms, and elect a President and Treasurer from among their number. The election passed off very quietly. Only 165 votes were polled.

The installation of officers occurred on Thursday evening of this week. A. S. Hallidie was elected President, Chas. R. Steiger, Vice President, H. L. Davis, Treasurer, Geo. Pardy, Recording Secretary, and H. C. Kibbe, Corresponding Secretary.

The following distribution was made by drawing lots: Long term—A. S. Hallidie, H. L. Davis, G. Spaulding, David Kerr, J. O. Hanscom, S. H. Harmon and J. Roach. Short term—Geo. Pardy, C. R. Steiger, H. Chapman, Robert Ewing, James Moffit, B. P. Bruner and Henry C. Kibbe.

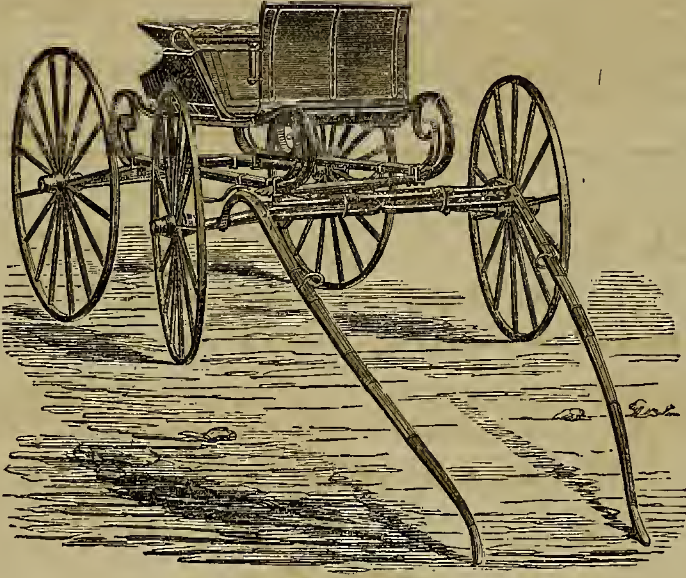
◆

We see it stated that on Wednesday an English company purchased a controlling interest (2,143 out of 3,000 shares) in the Sierra Buttes Quartz Mining Company. An agent of the purchasers started immediately to take possession of the mine.

The Balbach Buggy.

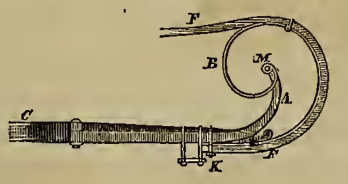
The comforts of civilization are being continually increased by worthy inventions, as the true economy of comfort in regard to health is getting to be better understood. It is a matter of no small moment to the hard worked business man, or to the tired laborer, to rest comfortably while being transferred from one place to another; and to change a painful journey into a refreshing ride or even a pleasure trip, is certainly an object worthy the attention of man.

Spring carriages may be justly reckoned among the indispensable conveniences of the age. Business and pleasure alike depend upon springs. Many and numerous are the devices now existing, and their manufacture has become an important business.



THE BALBACH BUGGY.

The leather rockaway strap—excellent as it is in many respects—lacks the elastic quality so essential to obviate the jars, while the elliptic steel springs, though breaking the jars, yet lack the rocking motion so necessary to overcome the jolting Six years ago, Mr. Balbach conceived the idea of constructing a wagon which should combine the two essentials of an easy perpendicular and a rocking motion. His first attempts have, however, been greatly improved, and our illustration shows the present light and elegant buggy which he constructs. The smaller figure serves to explain the construction of the spring.



As now made, the Balbach buggy has two parallel reaches, C, resting upon the open bolster, and connecting with the running gear. Light curved iron standards, A, in pairs, are firmly fastened by the bolts, L, L, on each side of the ends of the reaches, as shown in Fig. 2.

The beautiful curved steel spring, B, has its upper bearing within the standards, A, upon the bolt, M. The lower end of said spring is fastened to the underside of the reach, C, by the bolt, K, which may also fasten the ends of the strap, F, as seen in the figure.

The two rockaway straps, F, rest upon the curved steel springs, B, of which there are four. The carriage body is slightly curved, so as to evenly rock upon the strap, F, upon which it is fastened when ready for use. The curved steel spring, B, by having a double bearing, receives the strain under a weight evenly distributed throughout its entire length. And the greatest strength with perfect elasticity is thereby obtained. The best elastic steel spring cannot equal in ease of motion this curved steel spring while, in addition, every advantage of the rockaway motion is secured. Moreover, the saving in labor and in material, claimed in the construction of a carriage with this spring, and the cheapness of the spring itself, are important considerations for the manufacturers.

A patent for this improved spring was granted in 1869, to the inventor, Mr. John Balbach, of San José, through the agency of the SCIENTIFIC PRESS. For further particulars, or for the purchase of State or United States rights, apply to S. H. Herring, agent, care Dewey & Co., 414 Clay street, S. F.

◆

The Sierra Iron Works Company have had a number of men at work upon their property, for five or six months past, getting out fence posts and saw logs for lumber. The company are about erecting a sawmill, the first work of which will be to get out lumber for the construction of a tram-way, nine miles in length, to connect their works with the Central Pacific Railroad

Our Boston Friends now visiting San Francisco are cordially received. We judge them to be a good representation of the true type of Massachusetts business men. Many of them are wealthy, self-made men, who have gained their wealth without bluster. It is a pleasure to meet such men, so plain and unostentatious in all their intercourse.

Among others, we have received a call from Hon. Alvah Crocker, of Fitchburg, Mass., one of the heaviest paper manufacturers in the Union, well known among leading paper men, having supplied some of them constantly for over 30 years. Mr. Crocker is also one of the champions of the Hoosac Tunnel, without whose influence, skill and labors, the enterprise (which is now sure of success) would have been abandoned. He informs us that over 200 feet per month is now made in hard rock in the tunnel, and that the whole work will be finished in 1873. The tunnel will be five miles long, and not only Massachusetts, but all America may be proud of the complete success over difficulties far greater than any encountered in the Mt. Cenis Tunnel—built by the aid of two nations. As regards freights, the tunnel will bring the "Hub" one day nearer to San Francisco. Mr. Crocker speaks highly of the engineering accomplishments on the Central Pacific Railroad, such as can only be appreciated by discerning, practical railroad men. We like these practical, unassuming Boston men, and believe such visits are of mutual good.

◆

Cattle from the Mountains.—Cattle are coming to this city from almost every mountain-ward quarter. Some 220 head recently arrived via railroad from Idaho. Another and a still larger band is en route from the same locality, if they have not already arrived. The C. P. R. R. Co. have built a large corral near the freight depot at Winnemucca, Humboldt county, for the more convenient keeping and loading of cattle on the cars. Heretofore cattle reaching the line of the road near that point have been driven fifty miles along the road to reach a convenient point of shipment.

◆

Reports from Mexico state that a violent earthquake had occurred in the State of Oaxaca, and in the city of that name 103 persons were killed and 23 wounded. A third of the city is uninhabitable. The earthquake extended to the mines, where eleven persons were killed and many wounded. Buildings in all parts of the State are destroyed, and reports of additional deaths are expected.

Printing Press Patent Allowed.—A. H. Bangle, of Brooklyn, has just received a patent on his improved hand printing Press, We expect to illustrate it in the Press.

Communications.

Letter from White Pine.

[Written for the Scientific Press.]

Editors Press:—I have been in this district during the past month, and thinking that a few items from this camp would be of interest to your readers, have determined to write you concerning what I have seen. Hamilton is the largest of the three towns here, and has a fine brick Court House, a City Hall and other large buildings. I visited the Pioneer Foundry and Machine Shop, built by J. M. Lakeman, of Grass Valley, and J. Goddard, of this place, and find them fully prepared to do any work necessary for this locality, such as making mill-castings and machinery, turning, fitting and planing smithings, boiler work, etc. They are liberally patronized, and will doubtless, under the able management of Mr. J. Goddard, prove a great accommodation to the mills of this locality.

I also see that J. V. Hall, formerly of Sacramento, has established fine boiler works in this city, and doubt not that he will do well in this branch of business, as there will be plenty of repairing required about the smelting works. He seems to fill, in the best and most satisfactory manner, all orders for wrought or sheet-iron work.

Stage Lines.

There have been two stage lines running between Hamilton and Elko: The line of Woodruff, Ennor & Co., and that of Beachey, Wines & Co. I have had an opportunity of meeting Messrs. Woodruff & Ennor, and also of seeing how they conduct their business. They are both very clever and sociable gentlemen and what we would call "self-made men." They came to the country at an early day, and have gained the acquaintance and friendship of many who have traveled over their road. They have their line very well stocked with fine horses and very comfortable four and six-horse stages, and show every attention and care for the accommodation of the traveler, as I can attest from personal experience. I am told that they have been very successful, and have enjoyed a very large share of public patronage, always giving satisfaction. They are intending to take their stages and horses and move to Palisade station, and to start a new line from Palisade to Mineral Hill, thence to Eureka and so to White Pine, thus enabling visitors to see Eureka and Mineral Hill on the way to this locality. I intend paying those places a visit in a few weeks, and will then let your readers know what they have there, and how they are prospering.

Smelting Works—Treasure Hill Mines.

White Pine does not appear as lively as it did a year ago, but this has been the case with all other camps which were built up quickly during a mining excitement. Although times are dull here now, yet I am fully convinced that this is a good mining district, and, moreover, that the base metal mines are going to be the leading ones here. The scarcity of money in the market in all parts of our country has kept the capitalists away, and hence many of the mines have been stopped. I visited a large number of the mines and found them taking out plenty of ore, but the majority of the men employed are at work extracting the base ores from the smelting works. They have been very successful in smelting latterly. The Alsop and the White Pine smelting works are busy buying and smelting the ores for the *poor miner*. They pay from $10 to $25 or even $30 per ton for ore on the dump, and thus the miner is enabled to make a nice thing, if he strikes rich ore.

The Hidden Treasure is working a full force of men, and is looking very well. It is at present under the energetic management of Capt Turner.. The Eberhardt is employing a very small number just now, and it is rumored that the well known mine has been sold to an English company, for a very large sum, of course. The Aurora South and the Aurora North are both looking well, and have a large number of workmen engaged in raising ore. And many others are doing well, of whom I have not space to make special mention.

Litigation.

I understand, and know, that there is a great deal of litigation in this camp. I would wish to say a word in regard to a case taken to the Supreme Court some four or five months ago, involving the question as to the amount of work necessary to hold a claim for one year. This has not yet been decided, and an extremely bitter feeling exists here (as a large amount of property depends on the decision) on account of the delay. It is generally understood that there is but little business now before the Court, and hence everybody asks why the decision is withheld.

No doubt your readers are aware that Judge Bettey decided that a mine should have two days' work done for every 200 feet, or, in other words, two days' work for each claim. The old miners of this district, who made the mining laws, say they meant that two days' work would hold the claim for one year.

I see, in looking over the records, that there is not one notice in a hundred which designates the *position* of the claim, the statement being made simply that a person claims 100 feet running on this ledge or lode; as a consequence, notices have been floated about from one place to another. Miners ought to *insist*, when they make the laws, that when a claim is located, there should be some definite land-marks given, to determine its position. In regard to the amount of work required to hold a claim, I incline to agree with the Judge's opinion that two days' work is little enough for each 200 feet. Then a miner knows what his prospects really are, and at the same time he shows his true intention to work the mine, and not to make 30 or 40 locations and work just enough to hold them and keep off more industrious men. Many a case has occurred in this district where a man has worked faithfully and developed a claim, and then another man has come along asserting that he has an older location, and a long bitter lawsuit has followed.

I merely give these remarks for the consideration of others, believing them to agree with the ideas of many in this district, certainly of those with whom I have conversed.

The Diamond Drill.

While on Treasure Hill I went to see the operation of the Diamond Drill, which is at work in the Montgomery mine, northwest of the Eberhardt. The manager, Mr. H. M. True, is the agent for the drill and has taken a contract to bore in this mine. They are down about 25 feet, and are taking out a core one inch in diameter. I am informed that they can drill 30 feet in 10 hours. They use 400 gallons of water and half a cord of wood per day. The drill is a grand success and many mines will be prospected by means of it. It costs only $5 per foot to sink, and the mine owners find wood and water. It affords a quick way for testing mines. The core is taken out every 12 feet, and when traces of chlorides are seen it is assayed. Mr. Young and Mr. A. Mayberry are the engineers, and they seem to run the machine very successfully. I see that your valuable paper had it illustrated, under date of May 7th, and can say that, to get a clear idea of any new improvements, people can do no better than to subscribe for the Press. W. H. M.

Hamilton, Nev.

Battle Mountain District, Humboldt Co.

Editors Press:—The Shiloh mine is at present water-logged and awaiting machinery from below. The White mine, or extension of the Shiloh, was sold to a San Francisco company some two weeks since; work will probably be resumed the coming week. The Butte mine is looking well as usual. The Little Giant, at Battle Mountain, is pounding away on $150-ore. The Buena Vista mine, at this place, is promising finely; an average of six samples taken from the lead assayed $177, silver. Mr. Wardley is now shipping some high-grade ore from this mine to San Francisco. At Copper cañon the English Company and Johnson's Central mine are turning out splendid copper ore; the ore is carbonate, red and black oxide without any admixture of iron or sulphur, and of high grade.

Churchill Company and Black Cloud, the celebrated chromate of iron mines in this district, present as black and cloudy an appearance as ever, notwithstanding the efforts to push them forward with jaw-bone.

Galena, May 29th, 1870.

Gold Mining in Siberia.

The lessee of a gold deposit, which is generally situated in the forest swamps, far from any village, as before remarked [see article on "Prospecting in Siberia" in the Press of May 21st.—Eds.], has to transport the provisions and working apparatus for his mine through the desolate woods in winter on sledges at a very great expense. Most of the hired men are exiles, the remainder generally free peasants, who have been reduced in circumstances by misfortunes or misconduct. The procuring of the necessary workmen is a matter of no small trouble and expense. Before every summer campaign, the agents of the gold diggers travel about the country, like recruiting sergeants, and after giving many fair words and some hand money, take the passport of the man engaged as a security for his appearance. But although a passport is an indispensable document in Siberia, yet the workman often find means to obtain a new one under a different name, and engaging himself to another master, defrauds the first of his hand-money.

Workmen—Their Pay and Condition.

It may be easily imagined that, as the workmen are the refuse of society, the greatest discipline is necessary to keep them in order. The system of a secret police is here extended to its utmost limits. Scarcely has a suspicious word fallen, when the director is immediately informed of it, and takes his measures accordingly. Every man knows that he is watched, and is himself a spy on his companions.

Besides free rations, the ordinary wages of a common workman are $3 a month, but more experienced hands receive $10 or even $12 The pay dates from the day when the workman makes his appearance at the residence, and thence forward also his rations are served out to him. They consist of a pound of fresh or salt meat, or an equivalent portion of fish on fast days, cabbage, and groats for soup, besides fresh rye-bread and "quas" (the favorite national beverage) *ad libitum*. The whole number of workmen employed in a gold digging sub divide themselves into separate societies, each of which select a head man, to whom the provisions for his society are weighed out, and to whom all the other common interests are intrusted. The sale of spirituous liquors is strictly forbidden, and according to law no gin-shop is allowed to be open within 13 miles of a digging.

The pay and rations alone would be unsufficient to allure workmen to the diggings, the voyage there and back being very irksome and the labor very fatiguing. An excellent plan has therefore been devised for their encouragement. The contract for each workman distinctly specifies the quantity of his daily work, consisting of a certain number of wheelbarrows of sand —from 100 to 120, according to the distance from the spot where it is dug to the place where it is washed out—each reckoned at about 120 pounds, which one party has to fill, another to convey to the wash-stands, and the third to wash. The task is generally completed by noon or early in the afternoon. For any extra labor, and on Sundays and holidays, they receive an extra pay of 40 to 50 cents for every solotnik (about four-tenths of a pound) of gold they wash. Every evening the workmen bring the produce of their labor to the office, the gold is weighed in their presence and the society credited for the amount of its share. Thus the laborer may earn quite a sum of money. If the free labor is unproductive, many of the workmen desert or give up free labor altogether, to prevent which, it is customary in many places to pay them a fixed sum for extra work.

At the end of the season the workmen are paid off and receive provisions for their home journey. Generally they spend their money in the first village they reach, in drinking and gambling, and are obliged to bind themselves anew for the next season, and receive band-money from the agent, in order to be able to return to their families. After a winter of want and privation they return to the diggings, and thus, through their own folly, their life is spent in constant misery and hard labor.

During the winter the digging is deserted, except by an under-overseer and a few workmen, who prepare for the coming campaign, receive and warehouse the provisions sent, and guard the property. The director, meanwhile, is busy making purchases and attending to getting laborers. With the last sledge-transport he returns to the diggings to receive the workmen and see that all is ready for the summer. As his situation is one of great trust and responsibility, he is well paid. Maesnikow, for instance, paid his chief director $8,000 a year; and $1,200 to $1,600, besides free station, and a percentage of the gold produced, is the ordinary emolument.

Gold Produce of Eastern Siberia.

It is thus evident that the expenses of a Siberian gold mine are very large, but when fortune favors, the undertaker is amply rewarded; an annual produce of 400, 600 or 800 pounds of gold is by no means uncommon. In 1845, 458 workmen in the gold mines of Mariinsk produced 3,260 pounds of the precious metal; in 1844, 1,014 workmen in the mine of Kresdowosdwishensk produced 3,934 pounds; and in 1842, the mine of Spasky, near the source of the Peskin, yielded 4,000 pounds. From this last mine, from 1840 to 1845, $3,200,000 worth of gold was extracted. In 1860, the Garvilow mine yielded 4,100 pounds of pure gold. But in Siberia, as elsewhere, mining operations are frequently doomed to end in disappointment, especially if the ground has not been carefully examined beforehand, as the ore often occurs very unequally distributed and in small patches.

The entire gold produce of East Siberia amounted, in 1845, to 33,956 pounds, and in 1856 to about 44,000 pounds. Latterly in consequence of increasing wages and dearness of provisions, causing many of the less productive mines to be abandoned, it has somewhat diminished. In 1860, 31,796 men, 919 women and 8,751 horses and oxen were employed in the Siberian gold mines.

Gold Produce and Rich Families of the Ural.

Less rich in gold than the province of Jeniseik, but richer in copper and iron, and above all in platinum, is the Ural, where mining industry was first introduced by Peter the Great, at the close of the 17th century, and has since acquired a colossal development. Though gold was discovered in the Uralian province of Perm as early as 1745, yet its production on a large scale is of more modern date. In 1816 the amount of gold furnished by the Ural was only 235 pounds, while in 1834 it had increased to 16,200 pounds.

The discovery of the precious metals on the estates of the wealthy mine-proprietors of the Ural, already before this among the wealthiest of the empire, has increased their riches enormously. Werch Issetsk and Werchne Tagilsk, in the province of Perm, belonging to the Jakowlew family, have an extent of over 3,000,000 acres, with a population of 11,000 souls. Besides iron and copper, their chief produce, these estates yielded, in 1834, 2,320 pounds of gold. Nishne-Taglisk, belonging, since 1725, to the Demidoffs, is a still more magnificent possession, extending over 4,000,000 acres, and with a population, in 1834, of 20,000. That year it produced, besides vast quantities of iron and copper, no less than 1,160 pounds of gold and 4,523 pounds of platinum. The town of Nishne-Taglisk has about 15,000 inhabitants. The Demidoff family have established schools for the free education and maintenance of boys, and provided for sending those who distinguish themselves to higher colleges. The palace of the family has a fine collection of paintings by the first Italian masters; but it is seldom if ever inhabited by the proprietors, who prefer Florence and Paris to the Ural. The founder of the family was an eminent gunsmith of Tula, whose abilities gained him the favor of Peter the Great and the gift of the mines on which the colossal fortune of his descendants has been raised.—*Dr. Hartwig.*

A great Polar expedition is being organized in Sweden, for 1871 and 1872, under the direction of Professor Nordenskjold, the celebrated scientific leader of the Swedish expedition of 1863. Parry's attempt to reach the Pole by pushing on to the north of Spitzbergen, is to be repeated, and it is proposed to winter on one of the Seven Islands. Professor Nordenskjold intends to proceed to Greenland this summer to purchase dogs for the sledges and procure some necessary information.

On the last day of August, 1870, will take place in Geneva, Switzerland, a congress of the geologists of the Alps. This body embraces those savants of Switzerland, France, Italy, Germany and Austria who have made a specialty of the geology of the Alps. The session will last three days, and then excursions will be made to the most interesting spots (in a geological point of view) in that vicinity.

Olives in San Diego.—The San Diego *Union* says a larger crop of olives is expected on the old Mission plantation than has been known since 1847. The yield will be four-fold that of last year. This ancient plantation seems to be renewing its youth.

Mechanical Progress.

The "Victoria Stone."

A new artificial stone, invented by Rev. H. Highton, is described by *Engineering* for May 13th: "The process of manufacture consists in mixing broken granite with hydraulic cement and steeping the whole when set in a solution of silica. Two kinds of granite are used, Mount Sorrel and Guernsey. This is broken up into small fragments on the works. It is then mixed with Portland cement in the proportions of four of granite to one of cement, sufficient water being added to render it of a pasty consistency. In this state it is filled into the moulding frames, and allowed to stand for four days to dry. It is then taken from the mould and placed in a solution of silicate of soda, where it remains for two days, when it is ready for the market. * * The material produced is known as the Victoria stone, or petrified concrete, and the objects moulded from it are flagging, sinks, mantel-pieces, coping, and cap stones, sills, stairs, and such like articles. It is not so applicable for finely cut mouldings. * * A slab of the concrete two feet wide and two inches thick resting loosely on supports two feet apart, will bear in ten days time an average weight of 700 pounds in the center. After having been steeped in the silicate bath, it will sustain more than 1,000 pounds, whilst in five months it will carry 1,700 pounds, and in nine months 2,400 pounds. The crushing strength was found by Mr. Kirkaldy to be 6,441 pounds per square inch. A block presenting a surface of six inches by nine inches, sustained a weight of nearly 160 tons. At a London brewery it has been laid to replace ordinary paving which was constantly being broken by the rough handling of barrels. Since the Victoria stone has been laid not one slab has been broken."

Furrowing in Locomotive Boilers.—The probable cause of this is thus given by John G. Winston, an English engineer: "When a boiler is perfectly cylindrical, with butt joints and the strips outside, no furrowing is observed; with the strips inside, or with lap joints, furrowing takes place. Now, in my opinion, the strips and lap joints are the obstructions, causing these furrows; the steam from the tubes, shooting the water against the edges of the plates, is repelled, and the racing of the water from the fire-box end causes a rapid current to flow parallel with the joints, this upward and repelling and onward action of the confined water inducing more friction, and, consequently, keeping this part of the boiler in a raw state, more subject to corrosion. When the edges of the plates are placed downward, they are more liable to form furrows. The best cure is by making outside strips strong enough with butt joints and a proper form of rivet, which I maintain is a double counterlap."

Steam Boilers Become Brittle by Use. Mr. Peter Carmichael recently read a paper upon steam boilers before the Scotch Institution of Engineers, in the course of which he mentioned that it had been found that "all qualities of iron get hard and brittle after the boilers have been at work more than a dozen years, more especially where exposed to the action of the fire; and that in the furnaces, even Lowmoor iron becomes as brittle as common iron in that time, and great care has to be taken in making repairs to prevent the plates from cracking. For this reason sixteen to seventeen years is long enough for a boiler to be in use, at a pressure of 40 pounds to 45 pounds. If used longer, the pressure ought to be lowered." Two boilers which had been in use nineteen years, and which required repairs, were found by Mr. C. so brittle that the rivet heads on the outside flew off when the inside heads were struck; showing that the rivets had deteriorated as much as the plates.

The Steam Man.—This machine, now on exhibition in New York, is spoken of as a rather curious automaton, much more satisfactory than the one exhibited in that city two or three years since. A Behrens rotary engine at the "stern" drives a screw which actuates worm gears, working eccentrics by which the legs are alternately moved. These legs are straight bars, set in the middle of large blocks of iron which serve as feet. The boiler is in the body of the "man," and the smoke escapes through a hole in the crown of the hat. The gait is unsteady, and the steps very short.

Strength of Cast Iron.—At a meeting of the Institution of Civil Engineers, in London May 3d, Mr. George Berkley read a paper from an abstract of which we take the following:

"With respect to cast iron, it was stated that a mixture of irons for sleepers had produced bars 2 in. by 1 in. in section, which, when placed on bearings 3 ft. apart, had on the average of 1,151 experiments during the last three years borne 33 4 cwt. placed on the centre, and castings 1½ in. in length and 1 in. square, which on the average of 1,002 experiments had borne 13.07 tons of tensile strain. * * There would be a difference of about 16 per cent. between the weight that a 2 in. by 1 in. test-bar would support when cast on edge and proved as cast, and that which it would support when proved with the underside as cast placed at the top as proved; and a difference of about 8 per cent. between the weight the same test-bar would support if cast on its side or end, and proved on edge. This difference it would be necessary to take into consideration in estimating the strength of a large casting made from the same metal as that used in the test-bars. Another, and probably the most important practical consideration, in respect of the strength of castings, was the proportions of their several parts being such as would free them as much as possible from unequal contraction in cooling. It was not often practicable to effect that which would avoid this—viz: to adopt an equal thickness of metal in all parts of the casting; and it was therefore important that means should prevent the castings from cooling too be taken to quickly."

Manufacture of Grape Sugar from Corn.—Large factories for this purpose have recently been established in New Orleans, Buffalo, and Brooklyn. The corn is steeped in weak soda lye, for the purpose of softening the husk and gluten, and is then ground wet and run through revolving sieves to separate impurities; afterwards it is made to flow through ways or troughs, in which the starch gradually settles as a white powder. The wash water is run into a large cistern, and allowed to ferment and produce a weak vinegar. The starch from the troughs is put wet into the mash tub, and treated with water containing one per cent. of sulphuric acid, for eight hours. The acid is neutralized with chalk or carbonate of lime, and the liquid evaporated to get rid of the gypsum, and afterwards further evaporated in vacuum pans, and run into barrels ready for crystallization.

Estimation of Carbon in Pig-Iron.—A weighed quantity of the iron is placed on a small porcelain boat, and introduced into a hard glass combustion tube, placed in a combustion furnace, and, when red hot, a current of chlorine gas, dried by making it pass over pieces of pumice-stone moistened with strong sulphuric acid, is passed over; the current of gas and application of a low red heat is continued until all the iron is volatilized as chlorido. The carbon left in 'the small boat is, after the apparatus has cooled, placed in a porcelain tube and burned. After being heated to redness in a current of oxygen, the products of the composition are taken up by Liebig's potash bulbs. Great care is required that the chlorine be thoroughly dry, since, otherwise, hydro-carbons may be formed and some carbon lost.

How to Use a File.—We give two or three hints from the *Irish Builder:* "In filing flat surfaces, a 'surface plate' is used to enable the operator to finish the work with accuracy. This is merely a cast-iron plate planed to a true surface. Some red lead is rubbed on this plate; then the piece of work is rubbed on, and wherever the work is reddened it shows that that part is above the level, and has to be filed down; and this testing and filing is carried on until the work is perfectly true. It saves the file to draw it back at each stroke as lightly as possible. There is economy in using the files first on brass or cast iron, and afterwards on wrought iron."

Ericsson's Submarine Attack.—Capt. E.'s new plan is based upon the idea that a projectile, so constructed that its specific gravity is the same as that of water, may be made to penetrate the surface at such an angle that the straight line it will pursue after penetrating the surface, shall bring it into contact with the submerged part of the hull of any vessel toward which it may be directed;—which, of course, would be fatal to any of the breastwork iron-clad vessels, the armor of which does not inclose the submerged portion of their hulls.

Scientific Progress.

The Newall Telescope.

Nature describes and illustrates this splendid instrument—now so far completed that it has been moved from the works of Cooke & Sons, the makers at York, to Mr. Newall's observatory. We quote and condense: "The general design and appearance of this monster among telescopes is the same as that of the well known Cooke equatorials; but the extraordinary size of all the parts has necessitated the special arrangement of most of them. The length of the tube, including dew-cap and eye-end, is thirty-two feet, and it is of a cigar shape; the diameter at the object-end being twenty-seven inches, and at the center of the tube thirty-four inches. The cast-iron pillar supporting the whole is twenty-nine feet in height from the ground to the center of the declination axis, when horizontal; and the base of it is five feet, nine inches in diameter. The trough for the polar axis alone weighs twenty-four cwt., the weight of the whole instrument being nearly nine tons. The tube is constructed of steel plates riveted together, and is made in five lengths, screwed together with bolts and flanges. The plates of the central length are one-eighth of an inch thick, and those of each end one-sixteenth thick, so as to reduce the weight of the ends as much as possible, and avoid flexure. The object-glass has an aperture of 25 inches nearly. The focal length of the lens is twenty-nine feet. Attached to the eye-end of the tube are two finders, each four-inch aperture; they are fixed above and below the eye-end of the main tube, so that one may be readily accessible in all positions of the instrument. It is also supplied with a telescope having an O. G. of 6½-inches. This is fixed between the two finders, and is for the purpose of assisting in the observations of comets and other objects for which the large instrument is not so suitable. The clock for driving this monster telescope is in the upper part of the pillar, and is of comparatively small proportions, the instrument being so nicely counterpoised that a very slight power is required to be exerted by the clock, through the tangent screw, on the driving wheel (seven-feet diameter), in order to give the necessary equatorial motion."

Floating Matter in Strong Light.—Prof. Tyndall, in his late experiments with concentrated beams of light, observed that when the track of the beam was plainly defined in the floating matter of the air, the flame of an alcohol lamp, held below the luminous band, seemed to cast into it a column of black smoke. A hydrogen flame produced the same effect, which was no doubt due to the destruction of the floating matter, and the consequent production of a non-luminous condition like that of planetary space, by the removal of all particles capable of reflecting light. It was then, however, noticed that a red-hot poker produced a similar effect, though less in degree, and that even a flash of hot water likewise developed similar effect, though with yet less intensity. The explanation of this is, that the pure air, being expanded by the heat much more in proportion than the solid particles, was caused to produce ascending currents of entire purity, the dust particles being left behind.

Size of Liquid Drops.—Quincke, of Berlin, has found that the size of drops bears a fixed relation to the chemical composition of the liquid. He has proved experimentally that all liquids, at a temperature near their liquefying point, have specific cohesions, which are proportionate to the numbers 1, 2, 3, 4, etc. Taking the specific cohesion of the metallic bromides and iodides as 1, that of mercury, the nitrates, the metallic chlorides, the sugars, and the fats will be 2; that of water, the carbonates, the sulphates, and probably also the phosphates, will be 4. In the case of the metals (referred to the same standard), the specific cohesion of lead, bismuth, and antimony is 2; that of platinum, gold, silver, cadmium, tin, and copper, is 4; that of zinc, iron, and palladium, 6; that of sodium, 12.—*Boston Journal of Chemistry.*

Speed of Electric Signals.—It is remarked that wires buried in the earth transmit slowly, like submarine cables. Wires placed upon poles, but slightly elevated, transmit signals with a velocity of 12,000 miles per second, while those at a considerable hight give a velocity of 16-000 or 20,000 miles.

Mechanical Effects of Magnetization.—The following is from a lecture by Prof. Tyndall: "The effect I wish to make manifest was discovered by Mr. Joule, and was subsequently examined by MM. De la Rive, Wertheim, Marian, Matteucci and Wartmann. It is this: At the moment when the current passes through the coil surrounding the electro-magnet, a clink is heard emanating from the body of the iron, and at the moment the current ceases a clink is also heard. In fact, the acts of magnetization and demagnetization so stir the particles of the magnetized body that they, in their turn, can stir the air and send sonorous impulses to our auditory nerves. The sounds occur at the moment of magnetization, and at the moment when magnetization ceases; hence, if a means be devised of making and breaking, in quick succession, the circuit through which the current flows, we shall obtain an equally quick succession of sounds. I do this by means of a contact-breaker which belongs to a Ruhmkorff's induction coil. A thin bar of iron stretches from one of the bridges of this monochord to the other. This bar is placed in a glass tube, which is surrounded by copper wire. The contact-breaker is placed in a distant room, so that you cannot hear its noise. The current is now active, and every individual in this large assembly hears something between a dry crackle and a musical sound issuing from the bar in consequence of its successive magnetization and demagnetization."

Hydrogen Manufacture.—Du Motay and Maréchal have suggested a new process for the preparation of hydrogen on a large scale. It consists in heating to redness a mixture of damp coals and alkaline hydrates. A mixture of hydrogen and carbonic acid is thus disengaged, and conducted over certain carbonates, which retain the carbonic acid and become bicarbonates. The pure hydrogen is collected in a gasometer to be used as required. The bicarbonates are employed as such, or as reservoirs of carbonic acid. As to the oxides produced by the carbonization of the alkaline coals, they may be utilized for the purposes of agriculture or other industries, or, better, to form the hydrates for subsequent operations, They likewise propose to produce pure hydrogen by passing ordinary illuminating gas over lime heated to cherry redness; the dry residue will be carbonate of lime.—*The Scientific Review.*

Tetrabromide of Carbon.—At a late meeting of the Chemical Society in London, Messrs. Bolas and Gloves communicated a paper on this newly discovered combination. It can be obtained by various methods, amongst others by heating bisulphide of carbon with bromide of iodine in a sealed tube to a temperature of 150 deg. Cent. for about forty-eight hours. The bromide of iodine can also be replaced by terbromide of antimony. Carbon tetrabromide is a white crystalline substance, melting at 91 deg. Cent., insoluble in water, but readily soluble in ether, chloroform, benzol, American oil, and hot alcohol, from which it is deposited on cooling in lustrous crystalline plates. Sodium amalgam reduces it first to bromoform and then to methylene dibromide. The authors propose to carry on the investigation.

Effect of Cold upon Silkworms' Eggs. M. Duclaux has lately been experimenting on the effect of certain gases in retarding the incubation of silkworms' eggs. He has also been trying the effect of cold upon the same organisms, and finds that instead of retarding the period of incubation, it accelerated it; in fact, that eggs laid in autumn and left to themselves would only incubate in spring; but if subjected to the action of a freezing mixture for forty days, they would hatch into larvæ immediately afterwards, on being submitted to the action of a gentle heat.

Movements of Protoplasm and Chlorophyll.—Borodine has seen remarkable movements of the chlorophyll-grains in terrestrial plants. In diffused light, the grains are applied to the surfaces of the cells parallel to the surface of the leaf or other organ; under direct light they promptly move away to the side walls to return when the light is diminished. Rose, more recently, concludes that these movements do not originate in the grains of chlorophyll, but belong to the protoplasm in which they are imbedded.

Mining Summary.

The following information is gleaned mostly from journals published in the interior, in close proximity to the mines mentioned.

California.

ALPINE COUNTY.

Globe.—*Miner*, May 28th: J. Winchester, president, is on his way from New York to push the work and erect a mill.

Ore Drift.—The upper drift in the Schenectady is following a vein said to contain the best ore ever found in the mine. It is thought the M. C. drift is fast approaching the ore chute.

The M. C. mill will next week crush several tons of rock from the Tarshish lode for two of the claims, that a test may be made.

Items.—*Chronicle*, 28th: Leviathan has contracted for 20,000 bushels of charcoal. ....A larger force is at work on the Tarshish....Mountain is assessed $2 per share.

CALAVERAS COUNTY.

Petticoat.—*Chronicle*, June 4th: G. W. Hopkins, proprietor, on Wednesday proceeded to Railroad flat for the purpose of paying all indebtedness. We are informed that negotiations for the sale of the mine are pending.

Rich Rock.—We have been shown, by Mr. Lonttit some of the richest specimens of gold-bearing quartz we ever saw. Three pans from the lead that produced the specimens yielded $1,200. Mr. Johnson, Sport Hill, is one of the owners.

Custom Mill.—The Hepburn mill, at Railroad, which has been reconstructed by A. F. Burr, will commence crushing Monday.

In Operation. — The new hoisting works of Lewis Bros., Wet gulch, commenced operations yesterday. The machinery formerly belonged to the Golden Gate Mining Co.

Railroad Flat.—Cor. of same: At West Point, I found the mills all running. Ben Carlton's has been kept busy all winter. Thoss' works are driving ahead at Smith's mill; Lascey's mill, on the Middle fork, is also in motion. The miners are all at work. Placer miners have done very well during the winter. Adley's claim, Big flat, has paid remarkably well. Johnson's, on Soaproot gulch has, been remunerative, as well as many others.

El Dorado.—Cor. of same: The camp once so rich in placer mines, has now opened out some of the richest quartz in the county. The El Dorado mine and mill has been leased to O. B. Fenner & Co. This mine has been sunk to a depth of 140 feet and opened a ledge eight feet in thickness. The Rose Hill mine has had a crushing of 70 tons of ore which yielded $10, per ton. The shaft is sunk 60 feet, with a cross cut at the bottom that shows a well-defined ledge 22 feet in width. Mr. Rodocino proposes to run a tunnel immediately, cut the ledge at a depth of 350 feet, and erect a mill of 20 stamps, capable of crushing 40 tons per day, with water power.

EL DORADO COUNTY.

The Porphyry.—Placerville *Democrat*, June 4th: On Wednesday we made a visit to this ledge on Quartz hill. We found the parties busy at work. The rock becomes harder as they go down. Free gold is found in pockets, some of them very rich. Redd & Co. have done a good deal of work. Ollis & Co., and Davis & Co., have fine prospects. Mr. Fiske has already taken out a very nice sum from his claim. H. Louis is running a tunnel into the hill, and thinks he is close upon the ledge. He has already got good prospects. Hodge & Co. have opened their claims at different points, and rumor has it that big money has rewarded them. Van Hooker showed us a fine prospect from sulphurets at his lowest depth. The rock is full of them.

Georgetown.—Cor of same: The Eureka claim after running five days and a half broke one of their dies and cleaned up twenty-four ounces of amalgam, valued at $300. This claim is the first northern extension of the Woodside. There is some free gold in the rock, and the owners say that if it will pay the expenses that they can make a good thing out of the sulphurets. There is an eight stamp battery, and it will crush a ton to the stamp per day, and they estimate that a ton of sulphurets can be saved per day, which have assayed from seventy-five to twenty-seven hundred dollars per ton.

LOS ANGELES COUNTY.

Zapata Silver Mine.—*News*, May 28th: This is in San Gabriel cañon. Dr. Winston and others, who purchased the mine some years since, have driven a tunnel in 530 feet. One foot a day is the progress now made with Giant powder. Appearances are promising.

Gold Bullion.—Yesterday 236 ounces of gold bullion, the product of the Eureka mine, Soledad, was received by J. A. Hayward & Co. Value, upwards of $5,000.

MARIPOSA COUNTY.

Struck It.—*Gazette*, June 3d: W. H. Ames has an uncommonly good thing in quartz, or talc, near the head of Hell hollow, just within the line of the Mariposa Estate. Some Mexicans found a vein which yielded gold, upon which they sunk a small shaft and took out mineral which they worked in an arastra. Mr. Ames bought out the Mexicans, and obtained a lease of the ground from the Estate. He is now down 50 feet, and has a vein of rich rock, one foot wide, and enlarging, and so soft that it is easily worked with pick and shovel. Our informant says the rock will pay $125 to $200 per ton.

Quartzburg.—*Free Press*, May 21st: All that is left of what was once the town of Quartzburg, viz.: a storehouse, dwelling, stable, corral, and outbuildings, was disposed of by Major Hardwick, a few weeks since, to the Washington Mining Co.

NEVADA COUNTY.

Branch Mint Mine.—Grass Valley *Union*, May 31st: The tunnel is into the ridge nearly 300 feet. The work is pushed day and night. The whole length required to strike the ledge is 440 feet.

Badger Mine.—Saturday steam was raised. This mine has not been worked for years.

Town Talk.—Same of June 1st: This gravel mine gave at its clean-up on Monday $1,400 for a run of ten days.

Specimens.—Same of 2d: We saw, yesterday, four quartz specimens from Brown Bros. diggings on Squirrel creek. The four were worth $90 to 100.

Moore's and Woolsey's.—*Transcript*, May 31st: The miners at both flats are busy. On Saturday one company cleaned up $6,000 and another $5,000.

Gravel.—A company of twelve have located 3,600 feet on a splendid gravel range on the head waters of Deer creek. They have sunk a shaft 95 feet and found good prospects.

Bourbon Hill.—Same of 2d: A Welsh Co. on the east slope, have made a rich strike of gravel in their claims, which they have been prospecting for years.

French Corral.—In Eddy's claims, 35 men are running 1,000 inches of water. The mill for cement is kept in operation ten hours per day. Ball & Co's claims are constantly worked, and two mills are running. The Kansas Co. have stripped off the top to the cement channel, and are putting up a mill. Glaister & Harrison French's claims are running full handed.

"Orleans."—The rock taken out thus far has more than paid expenses.

Pittsburg.—Same of 3d: After a run of six days with ten stamps, there was cleaned up from the coppers on Wednesday $4,000. The mine never looked better.

Eureka Mine.—For 12 days run of the mill ending Saturday last the yield is something above $30,000.

Lindsey.—Same of 4th: The Bros. were recently offered $110,000 for their mine in Washington township. They have 15 stamps in constant operation, and will build another mill below, of 20 stamps. The ledge is 12 feet wide.

Sale of the Coe.—5th: Minor S. Martin has sold the Coe mine for $20,000.

PLACER COUNTY.

Rich Strike.—*Stars and Stripes*, June 2d: It is reported that very rich diggings have been struck above Michigan Bluffs, and as high as 114 ounces to the pan taken out.

Ophir.—Cor. of same: Clark and others discovered a ledge, three months ago, a short distance from Ophir, from which they recently had five tons of rock crushed, which yielded $85 per ton....Erskine & Nelson are crushing their rock at Staple's mill. The rock will yield $30 per ton.... Pugh's mill is being repaired....The Empire mill is running day and night....The Green ledge is sinking deeper with even better prospects....Anton Smith's ledge, below the Good Friday, is being reöpened. The rock heretofore yielded $30 per ton. ....Slawson, of the Minnesota, had a lot of rock crushed, which paid $40 per ton. ....Simmons & Manning own a ledge near the Buckeye, Muggin's Flat, from which they had 20 tons crushed. The return showed 58¾ ounces.

Ophir.—Cor. of *Herald*, 4th: Greene & Co. have received a net profit of $100 per foot for all sinking of shafts and running drifts since they purchased the ledge.... In the Good Friday, Jacob Cowar is sinking his shaft deeper....Spear & Lyon have leased to Jones & Co., Grass Valley. the Buckeye mine.....Mr. Battis, on the Shipley, is sinking, and finds plenty of free gold and sulphurets. His vein is between two and three feet wide at a depth of 48 ft. ....The crushing of F. Simons & Co., which yielded $35 per ton, came from their mine, near the Buckeye, on Humbug Flat.

Murderer's Bar.—Hagadorn & Phillips, of Nevada City, have secured three-fourths of a mile of mining ground on the American river, near Murderer's Bar. They have 20 Chinamen at work. They expect to employ at least 100 this summer

St. Patrick.—Grass Valley *Union*, May 31st: We are informed by good authority that the St. Patrick mine has been really sold, and that Capt. S. W. Lee and W. H. V. Cronise were the purchasers. Rumor says that the amount paid is $45,000. The ledge in the shaft on Saturday was showing better average rock than has yet been taken out of the mine.

PLUMAS COUNTY.

Lone Star.—Quincy *National*, May 28th: Mr. Lawrence, the owner, is repairing the mill with the intention of working rock from the Bullion mine.

Crescent.—Cor. of same: The Crescent Company, on the 24th, cleaned up $7,000, the result of two weeks' run.

Sawpit Flat.—Cor. of same: The Buckeye claims are taking out from six to eight dollars per day to the hand. The New York Co. is washing up drift dirt, and taking out from 130 to 200 ounces for every 36 hours' run. The Eagle Co. are washing up. The hydraulic claims prospect well. The Neversweat claim has not commenced washing, but chances are favorable.

SAN DIEGO COUNTY.

Los Angeles telegram, June 2d: Many miners are leaving the Julian district, discouraged at the prospect of a legal contest with the claimants of the Cuyamac grant. Among those remaining threats of summary measures towards those whose attempts to oust them are plentiful.

Rich Ore.—Los Angeles *News*, May 28: Another batch of ore arrived in this city yesterday from the Mount Vernon mine, Julian district, that surpasses anything in richness we have ever seen from that section.

SISKIYOU COUNTY.

Telegram, Yreka, June 2d: Mining on the South Fork is opening briskly. Enfield & Biernbaum are rigging up the most complete and extensive hydraulic in the county, and will commence piping in a few days. Other companies are preparing for work on a large scale. Some specimens of quartz are received from the Mammoth ledge of Orofine, in which gold is visible.

Humbug.—Yreka *Union*, June 3d: A few companies commenced to wash last week, and the balance will get at it this week. The season has been favorable for ground sluicing.

Little Humbug.—There are but three companies now mining. They are making now, while washing up, from $6 to $8 a day to the hand. The water will hold out so that they will be able to work pretty much all summer.

Custom Work.—The Oro Fino quartz mill is crushing rock from the ledge of Lauer & Co.

SHASTA COUNTY.

Janesville.—*Courier*, 4th: The parties who purchased the Cottonwood ditch are making preparations to commence enlarging it.

Good Prospect.—Last week several strangers came into this county hunting for work. They finally went to prospecting on a bar on Spring creek. After sinking a hole several feet, they took out a panful of gravel and obtained $2.25. The second pan yielded $2.50, and all the gravel since taken out of the hole has yielded almost as high.

SIERRA COUNTY.

Reis Mine.—*Messenger*, June 4th: We learn that a letter has been received from one of the Reis Bros., stating that the mine at Sierra Buttes, would probably be sold.

Iowa.—The company are putting up their engine, and will get to work about the 4th of July. There is five feet of water in their shaft.

Howland Flat.—Cor. of same: The Old Hawkeye Co. has in the past twelve weeks taken out 1,700 ounces of gold. They have now got their diggings fairly open, and are working 40 hands. Union Company has worked several hundred feet ahead of the Hawkeye, right along the dividing line, and are taking out their 200 ounces a week. The Union is working 85 hands. The Monumental are wiping off the old black marks. The Pittsburg Co. has bought the right of way from the Monumental, and is running a tunnel to open a piece of ground.

TRINITY COUNTY.

Lower Trinity.—*Journal*, 4th: The gold dust at Cox's bar is very fine, but mining is conducted on the plan of rushing off such vast amounts of gravel, that very small pan prospects are made to pay. Wm. Ashworth has struck a rich lead on Big bar. Wm. Patterson's claim has paid well this season. Wm. McCollum, at Corral camp, is doing well.

Canon Creek.—H. McIntire has struck it rich at the lower end of the corral at Cañon city. Accounts from all quarters of the county are encouraging. Wherever any prospecting has been done rich dirt has been found.

TUOLUMNE COUNTY.

Confidence Mine.—Sonora *Democrat*, 4th: The last run for eight days turned out $9,500. Total yield for May, $36,500. This is one of those mines that several parties worked at different times at a loss.

YUBA COUNTY.

Camptonville.—Marysville *Appeal*, 2d: Very little mining is going on, water being scarce. B. P. Hogg & Co. are running their hydraulic diggings.

Timbuctoo.—We understand that the usual amount of mining is being carried on and that water is plentiful.

Arizona.

Walker's District.—Prescott *Miner*, May 21st: The Eureka mill is now idle. The recent test by Mr. Tiernan, for Shoup, Jackson, and others, has satisfied all that the ores are rich. The company are now negotiating with the owner of the mill, and it is probable that they will buy or lease it. If so, work will soon be resumed.

C. Y. Shelton is working Vernon ore in his arastra. He thinks it will yield $300 to the ton.

Big Bug.—Mill running and paying. The ledge gets better and better.

Hassayampa.—Sterling sulphurets not yet all worked. The mill is idle.

Walnut Grove.—Several rich discoveries have recently been made, and parties are preparing to arastra. The owners of claims stand ready to give a fair show to capitalists who will erect mills.

Martinez.—Shafts are being sunk upon one or two lodes. It is asserted that the ore now being taken out is extraordinarily rich.

Wickenburg.—Messrs. Beach & Block inform us that the deep shaft in the Vulture lode is down 222 feet, and the ore rich in gold. The mill is running and paying.

Pima County.—New placer mines are said to have been discovered in the vicinity of Tucson and Tubac.

Colorado.

Items.—Central City *Register*, June 1st: Perrin's working of Pewabic ore yielded 11 ounces, not 46, as we had it....Charles Hoyt will soon commence work for a Boston company on the Cashier lode, Georgetown, the eastern extension of the Terrible. ....Stotts & Converse, on the Freeland, Trail creek, are in 200 feet, and have a good vein. Clark and partner, and Chavanne & Kramer are working the Coyote, and raising very rich ore....In Idaho district, Mr. Womack is at work on the Seaton. The ore sells for from $90 to $280 per ton at the smelting works—averaging for the whole crevice $150 per ton....The Gilpin and Coaley mines are looking better than ever....A load of ore from the Veto was recently sold to Updegraff for $375 per ton. The assay was $460.72 in silver..... Several companies in Russell district have started work again, encouraged by Perrin's success on the Pewabic. Some are already doing well. Two mills are running steadily.

Items.—*Herald*, June 1st: R. O. Old has 20 tons of first-class Terrible ore on the dump, and will soon make a shipment to England. Stewart is running the second-class ore....Dickenson & Dora will enlarge their mill on Chicago creek. Four arastras will be added for amalgamating purposes. The ore will be first pulverized finely by other means....The Brown Co. will finish another button of silver on Tuesday, which will weigh 400 pounds.... Mr. Lace started up the old Conelee mill, and will run on custom ore....The stamp mills of North Clear creek are at work, mostly on custom ore....Ore from the Grass Valley claim, on the Prize lode, is yielding 9 ounces and 16 pennyweights. ....Prof Frank Dibben has leased the Belmont lode, Argentine district....F. B. Gilbert has discovered a big thing in a lode on Turkey creek near the Syracuse mill, which he has leased.

Ni-Wot.—Georgetown *Miner*, May 26th: A company of Pennsylvania capitalists has been organized to develop this lode.

The Cliff has struck a pay-streak two feet wide. A tunnel will be run along the lode to the discovery shaft.

Silver Mountain.—Peter Ellis and Paul Steele a few days ago discovered what has the appearance of being a first-class gold lead. The vein is represented to have a width of two feet; the pay-streak is two inches.

Lake County.—At California gulch the miners on the Pilot lode are doing well, having taken out 25 pounds of gold in eight days.

Montana.

Last Chance.—Helena *Gazette*, May 30th: The ditch is selling 200 inches of water to three companies on the deep ground—Taylor, Thompson & Co., Williams & Co., and Getchell & Co. Below these, Messrs. Chessman, Hunt, Peterson, and others, are doing well. Labor is very scarce. Fifty miners could find employment to work nights. Mr. Steymist recently sold his claim—four hundred feet for eight thousand dollars. Col. Williams is selling one hundred inches of water on Helena hill. Mr. McComb took out a thousand dollars after one week's run, "shoveling in.' Dewar & Co's bed-rock flume is doing well. Heony & Co. are doing well. Marshall & Co. sold out to the Chinese, who are mining on the ground day and night. Dry gulch claim owners have united to run a drain ditch to ground, which has lain for years, and is richer than anything reported from Cedar creek.

Saur Kraut.—This new gulch, near Lincoln, is six to eight miles long, and in depth, to the bed-rock, 25 to 30 feet. The Lower Drain Co. have reached bed-rock, and 25 to 50 cents were obtained to the pan; out of one shaft, $2,50 to one pan.

Gold Hill.—Four companies are at work with plenty of water. Prior & Co. have a bed-rock flume, and are working Gold hill through it. The pay ground is from 50 to 75 feet deep. The last clean-up paid $100 per day to the hand. John Hughes and James Moore are running two sluices, and clean-up $15 per day to the hand.

Blackfoot.—All the mines are being worked successfully. In Ohio gulch, five men, in two weeks, cleaned up 100 ounces of gold dust. The miners on Illinois gulch struck good pay on bed-rock. Ten ounces were obtained from eight feet square. Ophir is doing well. The same of Carpenter's Bar, and Snow Shoe gulch.

Silver Bow.—Virginia *Times*, May 25th: From 1,000 to 1,200 men are at work; they have plenty of water; the claims all pay something more than wages, and many are very rich. Wages are $6 per day, dust.

Nevada.

COPE DISTRICT.

Bullion.—Elko *Independent*, June 1st: During May $31,569 in bullion was shipped from the Argenta,

Not Bad.—Two and one-half tons of ore from the Argenta, shipped to San Francisco ten days ago, for reduction, returned $1,242 to the ton.

The Elko *Chronicle* of 5th says: Drew & Co's mill is crushing ore from the Argenta, under an arrangement to work 1,600 tons. Excelsior is yielding rock in quantities, of a quality scarcely second to that of the Argenta. The Crescent has a shaft down 218 feet; the Monitor, 26 feet; Mountain City, 70; Sunny Hill, 35; Virginia, 40; Columbne, 45; Prosper, 45 feet. The Kanawha, a new discovery, exhibits some of the finest ore we saw in the camp.

HUMBOLDT.

Battle Mountain.—Elko *Chronicle*, June 5th: At Galena, Hogan & Co. have a smelting furnace ready to run, and only await a crusher from San Francisco. The White mine was sold a few days ago to a San Francisco company for a considerable sum. The 5-stamp mill of G. W. Fox is running day and night on Little Giant ore, with good results.

Haskel & Rogers are erecting a Haskel furnace at the mines, to work ore from the Bullion mine. This mine is 30 feet wide.

REESE RIVER.

Strike at Belmont.—*Reveille*, 30th: From Mr. James Groves we learn that an important strike was made in the El Dorado South, belonging to Leon & Co. A cut through the vein near the bottom of the incline, at a depth of 237 feet, disclosed a body of magnificent ore (stete feldtite).

WASHOE.

Occidental.—Gold Hill *News*, 4th: The grading for the new mill is completed and the stone work of the foundation soon will be. The mill will be completed in 70 days from the 1st inst.

Hale & Norcross.—Owing to the re-timbering of the shaft, no ore has been raised from the lower portion during the week, but the bullion yield shows no falling off, as a large amount of ore was accumulated in the dump.

Ophir.—The southwest drifts at the 700-foot level are looking well, and are likely to find ore when they get in far enough.

Chollar-Potosi.—Yielding 165 tons daily, assays averaging $50 per ton. The Belvidere section is yielding splendidly.

Savage.—Vigorous prospecting constantly going on with no new developments.

Gould & Curry.—Daily yield, 55 tons; assays averaging $44. The El Dorado and Potosi sections are the principal sources, and some ore of very high grade is being sacked daily.

Overman.—The 226 and 500-foot levels still constitute the principal ore resources of the mine. The daily yield has decreased, owing to most of the miners being discharged for reason known to the stock manipulators. The quality of ore is improved.

Hope.—The body of ore at the lowest level continues looking well. Both mills are kept running, the daily yield of the mine being from 30 to 35 tons of $20 ore daily.

Virginia Consolidated.—Drift west at the 500-foot level, from the new shaft, is in 403 feet to-day. The rock works favorably, and good progress is made.

Sierra Nevada.—Both mine and mill running satisfactorily.

Yellow Jacket.—The rich body of ore at the 900-foot level still continues its 230 tons of ore per day, being extracted from it and the level below.

Crown Point.—Daily yield 60 tons of low-grade ore from the upper levels.

Imperial-Empire.—Shaft 1,230 feet deep. Sinking resumed. The drift west at the 1,200-foot level is in 97 feet to-day. Average assays, $25 per ton.

Sacramento & Meredith.—The new mill is hammering away at a lively rate.

Daney.—Some fair ore comes from the west breast of this mine, also from the recently discovered vein near the clay.

Belcher.—Daily yield, 70 tons; principally from the 152-foot level and above it.

Kentuck.—Daily yield about 25 tons of fair grade ore, supplying the Pioneer mill. The working force has been much reduced.

Silver City.—*Enterprise*, 3d: This place has taken a new start. The miners have at length learned that they can dig out and work a few tons of ore without being capitalists to begin with. We have heard of one man who has obtained $4,000 from 11 tons of ore, reduced by an arastra worked by hand in his cellar—two men propelling the machine by means of cranks.

WHITE PINE.

Mining Sales.—*News*: The Trench mine is "high up" in London, and will probably be sold; the Borealis was sold yesterday to local capitalists for $10 per foot; a large portion of the Hemlock and Wabash Consolidation has been engaged, at heavy figures, by telegraph, in Philadelphia; the Pogonip and Othello has been sold to Chicago parties, and the money paid; the Tom Payne has been consolidated with the Chicago Mill Co.; and the Elko will probably be sold within three days; the Hemlock and Wabash is about taking in more ground, on Chloride flat, and there is talk of uniting all the companies claiming ground on the flat west of the Original Hidden Treasure.

Items.—Noonday hoists 15 tons daily. Much of it will mill $200 per ton.....Domingo has out 300 tons ore; first class is worth $60 per ton, second, $30. Cost, ready for the mill, $2.12 per ton. The ledge has been stripped 100 feet, showing a mass of ore 90 feet wide. Hemlock & Wabash shows richer ore...Moonlight has resumed operations...Silver Wedge has a vast quantity of high-grade ore in sight, Double Eagle gives again as good ore as it did last summer.....Uncle Sam has started again. So has Featherstone.....Cariboo is one of the most promising mines on the western slope of White Pine Mountain. The ledge is 4 to 7 feet wide. Twenty tons $100 ore on dump.....Trench is shipping $700 ore.....Domingo (base) assays up to $5,000....Yellowstone has a three-foot vein of pure metal.....Bromide Tunnel will soon resume work.

Bullion.—For the week ending May 30th, $29,074. For May, per Wells Fargo & Co., $189,104.83—of which $121,213.74 was sent West, and $57,991.09 East. Of this Original Hidden Treasure shipped $56,757.15. This shipment for May was from the Hamilton office only, and does not include that from Treasure City and Shermantown, which would swell the amount to over $200,000. For the year ending May 31st, Big Smoky mill produced 233 bars, valued at $450,372.

Ely District.—The Ely Co's ground consists of Burke No. 1, Burke No. 2, Vermillion, Creole, and Ely & Co. Tunnel. True fissure, six feet wide. Rich base ore down to 20 feet. Character then suddenly changes to free milling ore worth from $75 to $500 per ton. Pioche Co. has 2,000 tons ore now on dump, and is running a ten-mile tunnel along the whole length of the claim. Dutch boys have a 4-foot ledge of 200-dollar ore, and 30 tons on dump. The Pioche Co. claims the ground. Eureka tunnel claims all blind ledges, and all the water the tunnel may reach. Bowery has a 65-foot incline, and 100 tons of $250-ore on dump. O'Connor has a 6 foot ledge of $200-ore. Ely & Co. have a 5-stamp mill, and ship $18,000 per month. Pioche is building a 10-stamp mill. Sherwood and Vance, from New York, have each shipped a 10-stamp mill to the district.

Other Outside Districts.—Patterson is looking up....Silver Park still sends in bullion....Rich strike in Sacramento district, in the Snake Range....Work suspended at Egan for mill repairs and changes....Eureka turns out large quantities of bullion from its furnaces.

San Francisco Mining Stock Market.

The operations of the Board during the past week have been rather larger than the previous week, owing in a great measure to the heavy sales of Savage, which changed hands to the extent of nearly 2,600 shares on the 7th, and to nearly that number on the day following. Original Hidden Treasure also sold largely. As a general thing, mining stocks show no improvement, some continuing to hold their own from opening rates of the week, while others are declining from day to day. From a purely speculative point of view, some agree that this is a good time to invest, but when we look to the prospective production of the various companies, at least on the Comstock Lode, the prospect is not so encouraging. We notice that the shipments of bullion from Hamilton (White Pine), through Wells, Fargo & Co.'s Express, for the month of May, aggregate $179,205, of which amount $121,214 was sent West, and $57,991 to the East. From a private source we learn that the bullion product of the White Pine region is much larger than San Franciscans generally have an idea of. What they are now mostly in need of to facilitate shipments abroad is a railroad extending from Hamilton to Elko, a distance of about one hundred miles. This road, it is said, could be constructed in the course of a year, as it can be carried over a level stretch of country the entire distance. This would give facilities for the exportation of ores not before enjoyed, and would greatly enhance the value of mines located in that region.

Crown Point—was in the market to a less extent than the previous week, selling at a slight recession. For the week ending June 3d, 152¼ tons of ore were extracted, valued at $2,289 92, equal to $15 04 per ton. From the annual report of the Secretary we take the following statement, embracing the fiscal year from May 1, 1869, to May 1, 1870:

RECEIPTS.

Bullion	$76,167 45
Premium on bullion	375 81
Assessment No. 17	60,000 00
Assessment No. 18	90,000 00
Assessment No. 19	90,000 00
From Rhode Island Mill	26,770 83
From Mine—For hoisting ore for Kentuck and Yellow Jacket Companies, etc	22,124 70
Sundries	2,616 65
Cash on hand, May 1, 1869	42,679 76
	$410,735 20

DISBURSEMENTS.

Crown Point Mine	$196,428 64
Rhode Island Mill	10,910 94
Reducing ores	59,959 10
Virginia and Truckee Railroad	56,250 00
Legal expenses	4,631 10
General expenses—Gold Hill	15,665 25
Salaries, rents, etc.—San Francisco	8,663 62
Discount and Interest	4,422 18
Taxes	7,858 19
Sundries	6,637 30
Cash on hand, May 1, 1870	39,309 08
	$410,735 20

There were 5,391½ tons of ore reduced during the year, yielding $76,167 45, showing an average of $14 12½ per ton.

ASSETS.

Cash on hand, May 1, 1870	$ 37,573 60
Jno. P. Jones (cash at Gold Hill)	1,735 48
Rhode Island Mill	60,000 00
Mine improvements, buildings, etc.	80,000 00
Stock on hand at mine	8,705 21
Stock on hand at mill	9,320 08
Virginia and Truckee Railroad Company	74,103 02
Atlantic and Pacific Telegraph Company	490 20
Ore on hand at mill, 650 tons	8,131 50
	$280,059 09

Following are the officers of the Crown Point Mining Company: J. D. Fry, A. Hayward, Robert Sherwood, A. K. P. Harmon and H. C. Kibbe, Trustees. J. D. Fry, President; C. E. Elliott, Secretary, and John P. Jones, Superintendent.

Hale & Norcross—met with moderate sales, under a very considerable decline. The ore product for the week ending June 5th amounted to 731½ tons, all from the upper mine, as follows: 175-level, 233½; 300-level, 286½, and 535-level, 211½ tons. At the same time they had 4,832 tons on hand in the dumps. On the 6th inst., $20,021 in bullion was sent forward to the office in this city. On the 5th inst. they completed repairs on the shaft, and again resumed work in the lower levels as heretofore. They are now engaged in cross-cutting the vein on the lower level at a point 150 feet north of the shaft, and the Superintendent says the prospects appear to be good for satisfactory developments. A dividend of $7 50 per share is payable since the 10th inst.

Gould & Curry—under lessened sales, continues to decline. During the week ending June 6th, they mined 401 tons, showing an average assay value of $52 30 per ton. On the seventh station, cross-cut No. 1 has been abandoned. Work was resumed in No. 3, to which seven feet were added, and to cross-cut A 16 feet were added—both drifts running in quartz. The second station incline has been connected with the 100-level, and the Superintendent thinks they will get considerable ore from that point. On the 100-level a raise is being made from the fifth floor north, which shows some ore. They have resumed work in the winze on the El Dorado level, which has attained a depth of 62 feet, and shows a little ore. The bullion returns for the month of May aggregate $94,045, against $48,722 in April.

Chollar-Potosi—has been well maintained, and the offerings increased toward the close. They extracted 1,200 tons of ore during the week ending June 3d, showing an average assay value, from car samples, of $49 75 per ton. The Belvidere section, at the extreme south end, is being stoped out 26 feet in width, three-fourths of the entire body, it is reported, being a good quality of ore. The shaft from the surface, to connect with the winze coming up from below, came to ore at a depth of 20 feet, and a favorable report is given of this portion of the mine. No change in the Blue Wing section, which promises equally as well for June as it did for May. A dividend of $1 per share is payable on and after the 10th.

Belcher—changed hands to a much larger extent than usual, at a smart decline. On the 6th inst., $13,031 in bullion was forwarded to this city. The ore-seam cut 66 feet above the 262 level does not look so well within the past week; instead of being compact, it is divided into seams, but they may join together and form a body again. In a cross-cut about 130 feet south of the north boundary line, and about 35 feet above the 162 level, some good quartz has made its appearance, and is thought to be a continuation of a body of ore under the north incline, which assays $28 to the ton. They have resumed work on the 730 level. An assessment of $4 per share was levied on the 8th inst.

Kentuck—was little inquired for, selling at declining rates. During the week ending June 3d, 195¾ tons of ore were taken from the mine, showing an approximate yield of $3,745 96, equal to $19 21 per ton.——Imperial has not advanced. On the 7th inst., the winze was 77 feet in depth, the bottom showing no change. The face of the 1200 drift is still in porphyry.——Sierra Nevada sold to a less extent than last week. The bullion yield for the month of May aggregates $14,500.——Ophir shows no advance in the face of a delinquent assessment. Mail dates of the 7th state that "the Atchison Company has commenced suit against the Ophir Company, to quiet title to 500 feet on the north end of the Ophir location." Original Hidden Treasure (W. P.) disburses a dividend of $1 50 per share on and after the 10th.——The North Star (Cal.) also disburse a dividend of $1 per share on the 10th.—*Commercial Herald.*

——*Advertised in this journal.

England has 500 blast furnaces, which every year reduce 12,000,000 tons of ore to 4,800,000 tons of metal and which consume 14,000,000 tons of coal. The manufactured metal is worth about $160,000,000.

Farming and Gardening.

COMMUNICATIONS for this department are solicited from all parts of the Pacific States and Territories.

Grapes and Wine.

Large quantities of California wines are now being sent to the Atlantic States, while the product of our vineyards is becoming more and more appreciated there. Wine can be produced in this State at a figure so low as to give it a monopoly under the present tariff, and the greater cost of producing it in the Mississippi States. Vinters say that one gallon of good wine can be made here from fourteen pounds of grapes, and from three-quarters to one cent a pound can always be obtained for good grapes from the vinters. At the latter price grapes will pay the land-owner four times as much as he can realize from wheat or barley.

The chief aim of grape-growers should be to select none but the best varieties; for favorable results cannot be obtained from inferior fruit. Where the existing vines are inferior, they should be grafted, a process which may be easily effected by any one of the several plans heretofore proposed in the columns of the PRESS. If the vineyard is large, let a certain portion be changed every year, until all have been subjected to the knife. The grape-grower, as a general thing, should not put his grapes to press himself. It is better to sell to some experienced person who makes the manufacture of wine his especial business. When there is no such person within reasonable distance, let an association of growers be formed for the establishment of a manufactory, to be placed under the management of a competent person, where all the grapes of the neighborhood can be sent. In no other way can the production of wine be made a success.

Dealers are offering fifty and sixty cents, and more, per gallon, for extra wines, while it is with difficulty they can be prevailed upon to take inferior wines at from thirty-five or even twenty-five cents. It costs no more to raise good grapes than poor ones—while the profit is fully double.

STRAWBERRY PROFITS.—A widow lady in Santa Cruz received over $500 for the strawberries grown on a half acre of poorly-tended ground last season. It is getting to be a common thing in the East for females to plant and care for small fruits; and in every case where the land is suitable and the proper attention is bestowed, success has attended such enterprise. Could not some of our city girls better their conditions by engaging in this independent calling? Health, strength and happiness in the country, is better than the confined, restricted and insipid life of a shop-girl. No country offers better opportunity for such enterprise than California.

TREE PLANTING.—The State of Iowa planted, last year, about 15,000,000 trees, and will set out a still larger number this year. Two farmers, in one township in that State, have set out this spring 25,000 trees. This is at the rate of about five trees, annually, for each inhabitant, none too many to meet the demand for fruit, commerce, fuel and timber. California, although she is doing much in this direction, is still far behind the prairie State and her own actual need.

BLACKBERRIES.—Charles Berm, of Santa Cruz, informs us that he sold $80 worth of blackberris last season, the produce of less than a hundred plants growing along a fence in his garden. The plants were four years old.

TWENTY-TWO thousand head of sheep have been driven through Oroville within the past two weeks, for the mountain ranges, which are covered with the most luxuriant feed.

Improved Breeds of Sheep—The Wool Clip.

It is quite gratifying to observe that with the increase of the wool crop in this State, there is also a decided improvement in the quality of the fiber. Large numbers of the various high-blooded varieties are being introduced into the State from abroad, and industriously bred here, either pure or by judicious crossing.

One hundred one-year old half-breed Cotswold rams arrived in this city, from Snelling's, a few days since, to be distributed among breeders, as ordered here and in Sacramento. Their average cost was $15; average weight, 150 pounds.

Bardette Loomis, a famous Cotswold sheep-breeder of Hartford, Conn., has recently sold fifty pure-blooded rams to parties in Arizona.

G. W. Gridley, according to the Butte *Record*, has sheared the present season nineteen thousand sheep. Sixteen thousand of these, it is estimated, will average five pounds to the fleece, and three thousand lambs at two pounds per fleece; a total of eighty-three thousand pounds, or forty-one and a half tons. This is his clip for the year, and is held at twenty-five cents per pound, amounting to $20,750. Mr. Gridley expects to realize that figure in this city or ship his wool East.

Wool is arriving in this city in large quantities from the central and southern counties. Small lots are being forwarded to Stockton and other interior cities, where it is being readily disposed of at fair prices, for transhipment to this city. Large growers are forwarding their clips direct to this city, where better prices are obtained.

Oil-Meal for Calves.

A gentleman who has had some years experience in raising calves, informs us that with the use of oil-cake meal he can make skim-milk and whey equal in strength and richness to new milk. The calves like it just as well. It never physics them, and they thrive wonderfully on it. Their coats look sleek and glossy, and their eyes bright; while for healthy activity and rapid growth, new milk is not surpassed.

Oil-cake meal is very cheap, and but one pint is needed to enrich a bucket of milk. It appears to supply the necessary oil to the skim-milk, in place of the cream removed, and to further enrich the milk. It should be fed slightly warm,—about milk warm,—in little troughs made for the purpose. The calves soon learn to drink by letting them suck the fingers while dipping their noses into the feed; or a piece of white cotton cloth may be rolled up, and tacked, by one end, to the bottom of the feeding-trough. Place the opposite end, saturated with the milk, in the mouth of the calf, and he will readily suck as from the teat, and after a few trials will learn to drink. Many calves in this State are killed at birth to save the milk, when they can be easily, cheaply, and very profitably raised by feeding skim-milk or whey properly prepared in this way.

We have had some experience in feeding skim-milk, both sweet and sour, and with very good success, and we are favorably inclined to give full credit to the efficacy of oil-meal, though we never tried it. We have tried cornmeal, oatmeal and flour with skim-milk; but it is very liable to "scour," and work more injury to the calf than all the benefit amounts to. We advise our friends to try the oil-meal, and give us the results.

A HINT.—A French gardener finding a piece of woolen cloth, which had lodged in a tree, covered with caterpillars, acted upon the idea suggested, and placed woolen rags in several trees. Every morning he found them covered with caterpillars, which he easily removed.

Bones—How to Utilize Them.

There is nothing so valuable, in the form of manure, which the farmer wastes, as bones. They are exceedingly rich in plant food. The phosphorus which they contain is of the highest value to the farmer. They should never be wasted; but should always be applied to the soil, in some form. They may be applied to greater or less advantage in almost any form—buried whole, broken into fragments or splinters by pounding, ground into flour more or less fine, or dissolved by means of acids, etc.

There is no one practice among American farmers which deserves a sharper rebuke than that of permitting such vast quantities of this fertilizing material to be shipped abroad for improving the agriculture of foreign nations. Many thousands of tons collected in Chicago, Buffalo, New York and other Atlantic cities are thus shipped, every year, because our farmers will insist upon it that it don't pay to collect and utilize them at home. We are, therefore, all the more pleased to hear inquiries such as have called forth this writing, which we propose to extend to a series of several articles.

Bones, if applied whole, will occupy many years, the larger ones a century at least, in the process of decomposition, imparting all the while, slowly but perceptibly, food for vegetation. If cracked or broken their action is more rapid—indeed it is improved just in proportion to the degree of fineness to which the bones are reduced. When ground to a moderately fine powder, their action is about ten times as rapid as when employed whole. If chemically separated or dissolved in sulphuric acid, their action is three or four times as rapid as when merely ground into flour.

How to Reduce Them.

It has long been a problem how to reduce bones to fine dust or meal in the simplest and most economical manner, or otherwise make them available for use upon the farm. Our correspondent, "W.," of Weaver, suggests a small one-stamp mill, constructed similar to a quartz mill. We are of the opinion that however serviceable such a mill may be in the reduction of a brittle substance, like quartz, it would be a poor contrivance for reducing a fibrous substance, like bones.

Bone mills are usually made something after the manner of the Cornish rollers, such as are employed for crushing quartz. The rollers are arranged, one pair above another. The bones first pass between the upper ones, by which they are coarsely broken; then in succession through others, which reduce them finer and finer, until crushing has done all it can readily accomplish. They are sometimes, as a final process, passed between cutting rollers, armed with steel knives, and running very swiftly in opposite directions. A good bark mill, or any properly constructed conical crusher could no doubt be employed to advantage in crushing bones. The larger ones, however, would have to be broken up with a sledge-hammer. Rollers are very expensive, and suitable only for large bone-crushing establishments; while the conical crushers are comparatively cheap, and might be profitably put up in almost every town.

Sledge-hammering bones is sometimes attempted; but it requires a long time and hard work to crush a very small pile in this manner.

Burning Bones,

To render them brittle and easy to crush is a wasteful practice; as in the process of burning, all the nitrogenous matter, which is especially valuable, is driven off. There is a method, however, by which

Bones may be Softened and Made Brittle,

Without in any manner deteriorating from their manurial value. This may be done as follows: Collect as many bones as you desire to operate upon, and break up the larger ones with a sledge-hammer, or if you have access to a coarse grinding bark mill, all the better. Take a half hogshead, or dig a pit in clayey ground, according to the quantity of bones which you have on hand. It would be well to pound the bottom of the pit hard, and cover with clay, if dug in a porous soil, so as to prevent the escape of the liquor. Cover the bottom of the pit with a layer of fresh horse-dung, or other barnyard manure, and place thereupon a layer of bones. Repeat these layers alternately, until all the bones are thus disposed of. Moisten the heap, now and then, with water, liquid manure, or hot soap-suds. An active fermentation will be induced, under the influence of which the bones will soon become partially decomposed, soft and brittle, in which state they may be easily crushed in almost any kind of mill, or reduced quite fine on a flat rock under the face of a sledge-hammer or the head of an ax.

The addition to the heap of, say two bushels of good hard-wood ashes to a hogshead of the mixture will greatly hasten and perfect the process. The heap should remain undisturbed for six or eight months—a year would be better. It should be frequently moistened—in fact kept constantly wet, and the warmer the better.

[TO BE CONTINUED.]

Farming at Santa Cruz.

While this State is suffering throughout its whole length and breadth with a severe drouth, the farmers about Santa Cruz are luxuriating amidst a bountiful harvest. The pastures are green, the grain fields are magnificent, and the orchards are profuse in the richest foliage and in promise of fruit.

A gentle slope of low receding hills, interspersed with ravines and valleys reaches from the mountains to the sea,—the broad expansive ocean and the charming bay. The mountain forests of evergreens jut out here and there, in columns and squads towards the beach, as though alarmed at the roaring surf, and ready, with standards waving, to combat the threatening waters of the deep.

While in contrast, the well-tilled fields, the vineyards crowning the rounded hills, the gardens of vegetables, fruits and flowers are smiling peace and plenty. Then, tasteful cottage homes, midst cheerful grounds, winding roads and pleasant streets, busy factories of various sorts, churches, schools and healthful faces, all lend a cheer to the scene, and give life to the combined features of Nature, grand, sublime, mysterious and lovely.

More rain has fallen here than in most other places in the State. The proximity to the sea and protecting hills have broken the currents of drying air, and yielded moisture to the earth and growing vegetation. Santa Cruz is this year an oasis and a cheering place indeed, whether held in contrast or admired for its intrinsic beauties.

S. H. HERRING.

POSSIBILITIES OF FRUIT CULTURE.—It is difficult to set bounds to the possibilities of the improvement of fruit. The luscious peach has been produced, by careful cultivation, from a shrivelled, worthless, poisonous wild fruit, indigenous in Persia. The innumerable varieties of the apple, the prince of fruits, have all been derived from the tiny and distasteful crab apple. The once shapeless, pulpless tomato, under the hand of the careful culturist, is fast assuming large, beautiful and smooth proportions, filled with an almost seedless, rich and juicy pulp. So of almost every variety of fruit cultivated in the northern portions of the temperate zone.

The late Seth Boyden, the skillful and well-known horticulturist and strawberry fancier, said, a short time before his death, that if he was permitted to live twenty years longer, he would produce a strawberry as large as a pine apple, and as delicious as the best field strawberry. The possibilities of fruit culture are just beginning to be realized.

What I Know of Farming—No. 21.

Muck—How to Utilize It.

The time will be, I cannot doubt, when chemists can tell us the exact positive or relative value of a cord of muck—how this swamp or that pond affords a choice article, while the product of another will hardly pay for digging. There may be chemists whose judgment on these points is now worth far more than mine, since mine is worth exactly nothing. I *do* know, however, that muck is a valuable fertilizer, and that digging and composting it *does pay*. I judge that I have transferred at least three thousand loads of it from my swamp to my upland; and the effect has been all that I expected. Let me speak of muck generally, in the light of my own experience.

Wherever rocks in ridges come to the surface of the valley, plain, or gentle slope, water is apt to be collected or retained by them, forming ponds or shallower pools, which may or may not dry up in summer, but which are seldom dry late in autumn when plants are dying and leaves are falling. The latter, caught in their descent by the harsh winds of the season, are swept along the bare, dry ground, till they strike the water, which arrests their progress and soon engulfs them. Thus an acre of watery surface will often collect and retain the dead foliage of five to ten acres of forest; and next fall will render its kindred tribute, and the next, and the next, forever. There cannot be less than fifty millions of acres of swamps in our old States (including Maine); whereof I presume the larger area was covered with water until the slow contributions of leaves and weeds filled them above the level at which water is no longer retained on the surface. And still they are so moist and boggy, and their rank vegetation is so retentive, that the weeds swept in from the adjacent hills and glades are firmly retained and aid to increase the depth of their vegetable mold, which varies from a few inches to twenty and even thirty feet. In my old county of Westchester, I roughly estimate that there are at least five thousand acres of bog, whereof but a very few hundreds have yet been subdued to the uses of cultivation.

Whoever digs a quantity of swamp muck and applies it *directly* to his fields or gardens, will derive little or no immediate benefit therefrom. It is green, sour, cold, and more likely to cover his fields thickly and persistently with sorrel, eye-smart, rag-weed, pursley, and other infestations, than to add a bushel per acre to his crop of grain or roots. And thus many have tried muck, and, on trial, pronounced it a pestilent humbug.

But let any farmer turn his whole force into a bog or marsh directly after finishing his summer harvest (when it is apt to be driest and warmest), and, having freed it from water to the best of his ability, dig and draw out one hundred cords of its black, oozy substance, and he will know better than to unite in that hasty judgment. If the bog be near his farm-yard, let the muck be shoveled at once into a cart and drawn thither; but if not, let it be simply brought out in wheel-barrows and deposited, not more than two feet deep, on the most convenient bank that is well drained and perfectly dry. Here let it dry and drain till after fall harvest, and then begin to draw it gradually into the yards, and especially where it may be worked over by swine and scratched over for seeds and insects by fowls. Assuming that the farm-yard is lowest in the center and allows no liquid to escape save by evaporation, the muck may well be dumped on the dryer sides; thence, after being worked over and trampled through and through, to be shoveled into the center and replaced by fresh arrivals. A hundred cords may thus be so mixed and ripened as to be fit to draw out next May and used as a fertilizer for grain or roots, though, if not so treated, it should lie exposed to sun and wind a full year; being applied in the fall to crops of winter grain or spread upon the fields to be planted or sowed next spring. All the manure made during the winter should be spread over that which lies in the yard at least smoothly; and then new muck drawn in, to be rooted or scratched over, trampled into the underlying strata, and overspread in its turn. Thus treated, I am confident that each hundred cords of muck will be equal in value to an equal quantity of manure, though it may not give up its fertilizing properties so freely to the first crop that follows its application. I have land that did not yield (in pasture) the equivalent of half a ton of hay per annum when I bought it, that now yields at least three tons of good hay per annum; and its renovation is mainly due to a free application of swamp muck.

To those who have a good stock of animals, with muck convenient to their yards, I would not recommend any other treatment than the foregoing; but there are many who keep few animals, or whose muck-beds lie at the back of their farms, two or three hundred rods from their barns; while they wish to fertilize the fields in this quarter, which have been slighted in former applications, because of the distance over which the manure had to be hauled. If these possess or can buy good hard-wood, house-made ashes at twenty-five cents or less per bushel, I would say, mix these well, at the rate of two or three bushels per cord, with your muck as you dig it; work it over the next spring, and apply it the ensuing fall, so as to give a full year to ripen and sweeten, and it will be all right. But, if you have not and cannot get the ashes, and *can* procure dirty, refuse salt from some meat packer or wholesale grocer, apply this as you would have applied the ashes, but in rather larger quantity; and, if you can get neither ashes nor salt, use quicklime, as fresh and hot from the kiln as you can apply it. The best lime is that from burned oyster shells; I consider this, if nowise slaked, nearly equal to refuse salt; but oyster-shell lime is too dear at most inland points; and here the refuse of the kilns—that which is not good enough for mason-work—must be used. Usually, the lime-burner has a load or more of this at the clearing out of every kiln, which he will sell quite cheap if it be taken out of his way at once; and this should be looked for and secured. Being inferior in quality (often because imperfectly burned), it should be applied in larger quantity—not less than four bushels to each cord of muck.

I will not here describe the process of mixing salt with lime commended by Prof. Mapes, because it is not easy to bring these two ingredients together so as to mix them with the muck as it is dug; and, though I have used them after Prof. Mapes' recipe, and purpose to do so hereafter, I do not feel certain that any positive advantage results from their blended application as a chloride of lime. If I should gain further light on this point before completing this series, I shall not fail to impart it. —*Horace Greeley.*

American Wild Fruits.

Mr. James Lick, of San José, is the only person in this State, so far as we can ascertain, who has had the good taste and good sense to plant and cultivate that most delicious of American wild fruits the persimmon. Mr. Lick has several persimmon trees in full bearing. We ate some of the fruit last year and found it to be excellent, fully equal in flavor and development to that of the Atlantic States.

In view of the fact that every variety of fruit peculiar to the temperate zones reaches perfection here sooner than upon any other known locality on the continent, is it not suprising that our orchardists and farmers do not endeavor to cultivate some of the luscious wild fruits of the Eastern, Western and Southern States? There is the glorious Paw-paw, of Kentucky; the Chickasaw Plum, of Missouri; the Black Haw and wild Raspberry, of Indiana; the delicious Muscadine, of Louisiana and Mississippi; the Persimmon and Huckleberry, of North Carolina; the delicate Sarvace Berry and plump Dewberry, of Ohio—these and many other varieties of wild fruits, infinitely superior to the insipid trash we are now cultivating, could be easily and profitably raised in California. In addition to the wild fruits of the Eastern States, the country there, especially in the South and West, abounds with many desciduous nut-bearing trees, the fruit of which is acknowledged to be superior to anything obtained elsewhere. The Beach, the White-Hickory, the Black-Walnut, the Butter-nut, the Chesnut, the Chincopia and Pecan—all these are superb forest trees—ready growers and good bearers, and would thrive finely in this climate. We believe that California horticulturists have paid some attention to American nut-trees, but they have not given them that attention which they merit, and now that the railroad has brought us within a few days journey of the old States, we shall hope to see our farmers and gardeners ornamenting their homes with the familiar old fruit-bearing trees, such as gladdened our hearts a long time ago.—*San Jose Independent.*

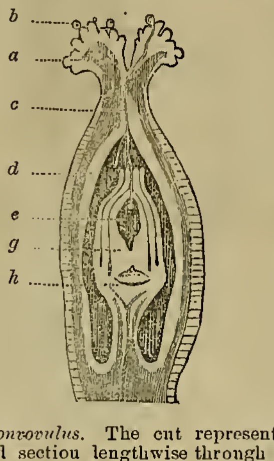
A CRUSADE against squirrels has been inaugurated in Contra Costa county. One man named Welch, has already killed over five thousand of them.

Fertilization, Fructification, Etc.

Following a description of "The Flower and its Organs," which appeared in our issue two weeks ago, we come naturally to the subject of fertilization and fructification. In describing this we quote, nearly *verbatim*, from "How Crops Grow," copying, also, from that work the accompanying illustration:

The grand function of the flower is *fructification.* For this purpose the pollen must fall upon or be carried by wind, insects, or other agencies, to the naked tip of the pistil. Thus situated, each pollen-grain sends out a slender tube of microscopic diameter, which penetrates the interior of the pistil until it enters the seed-sack and comes in contact with the ovule or rudimentary seed. This contact being established, the ovule is *fertilized* and begins to grow. Thenceforward the corolla and stamens usually wither, while the base of the pistil and the included ovules rapidly increase in size until the seeds are ripe, when the seed-vessel falls to the ground or else opens and releases its contents.

The accompanying figure exhibits the process of fertilization as observed in a plant allied to buckwheat—viz: the *Polygonum convovulus.*



The cut represents a magnified section lengthwise through the short pistil; *a* is the stigma or summit of the pistil; *b* are grains of pollen; *c* are pollen tubes that have penetrated into the seed-vessel which forms the base of the pistil; one has entered the mouth of the rudimentary seed, *g*, and reached the embryo sack, *e*, within which it causes the development of a germ; *d* represents the interior wall of the seed-vessel; *h*, the base of the seed and its attachment to the seed-vessel.

Artificial Fecundation

Has been proposed as a means of increasing the yield of certain crops. This has been effected by agitating the heads of grain, at the time when the pollen is ripe, in order to insure its distribution, by two men traversing the field, carrying a rope between them so as to lightly brush over the heads. The plan appears to have been very useful in some cases, though in many trials no good effects have followed its application. We must therefore conclude that agitation by the winds and the good offices of insects commonly render artificial assistance in the fecundating process entirely superfluous.

Hybridizing.

As the union of the sexes of different kinds of animals sometimes results in the birth of a hybrid, so among plants, the ovules of one kind may be fertilized by the pollen of another, and the seed thus developed, in its growth, produces a hybrid plant. In both the animal and vegetable kingdoms, the limits within which hybridization is possible appear to be very narrow. It is only between *closely allied species* that fecundation can take place. Wheat, oats and barley show no tendency to "mix;" the pollen of each of these similar plants being incapable of fertilizing the ovules of the others.

In flower and fruit-culture, hybridization is practised, or attempted, as a means of producing new kinds. Thus the celebrated Rogers Seedling Grapes are believed to be hybrids between the European grape, *Vitis vinifera*, and the allied but distinct *Vitis labrusca*, of North America.

Hybridization between plants is effected, if at all, by removing from the flower of one kind the stamens before they shed their pollen, and dusting the summit of the pistil with pollen from another kind.

The mixing of different varieties, as commonly happens among maize, melons, etc., is not properly hybridization; this word would be used in the long-established sense. We are thus led to a brief notice of the meaning of the terms species and variety, and of the distinctions employed in botanical classification.

Species.

The idea of species as distinct from *variety* which has been held by most scientific authorities hitherto, is based primarily on the faculty of continued reproduction. The horse is a species comprising many varieties. The same is true of the ass. The horse and the ass by sexual union produce a hybrid—the mule,—but the sexual union of mules is without result. They cannot continue the mule as a distinct kind of animal—as a species. Among animals a species therefore comprises all those individuals which are related by common origin or fraternity, and which are capable of sexual fertility. This conception involves original and permanent differences between different species.

Varieties.

Individuals of the same species differ. In fact, no two individuals are quite alike. Circumstances of temperature, food, and habits of life, may cause variation from and back again to the original; and although variation may take a seemingly wide range, its bounds are fixed and do not touch specific characters.

Among plants, varieties may often be perpetuated by the seed. This is true of cereal and leguminous plants, which reproduce their kind with striking regularity. Other plants cannot be or are not reproduced unaltered by the seed, but are continued in the possession of their peculiarities by cuttings, layers and grafts, as in fruits. Here the individual plant is in a sense divided and multiplied. The species is *propagated*, but not *reproduced.* The fact that the seeds of a potato, a grape, an apple or pear, cannot be depended upon to reproduce the variety, may perhaps be more commonly due to unavoidable contact of pollen from other varieties, than to inability of the mother plant to perpetuate its peculiarities. That such inability often exists is, however, well established, and is, in general, most obvious in case of varieties that have to the greatest degree departed from the original specific type. Thus Nature puts the same limit to variation within a species that she has established against the mixing of species.

New (Supposed) Variety of Wheat.—The Marysville *Appeal* has seen a sample of wheat thought to be a new variety. Its history is given as follows: About two years ago Mr. J. A. Pearse, of Sutter county, found among some barley a kernel of wheat which arrested his attention, it being very large, and unlike the wheat common among the farmers here, resembling the white wheat. From this one kernel he experimented, and this year he expects to have as the result three hundred bushels. The wheat is large and well filled, containing double rows, four kernels to the bunch. The heads are quite lengthy and heavy. He has christened it the "Velvet Bearded" wheat, from the soft and velvety appearance of the beards.

Notices to Correspondents.

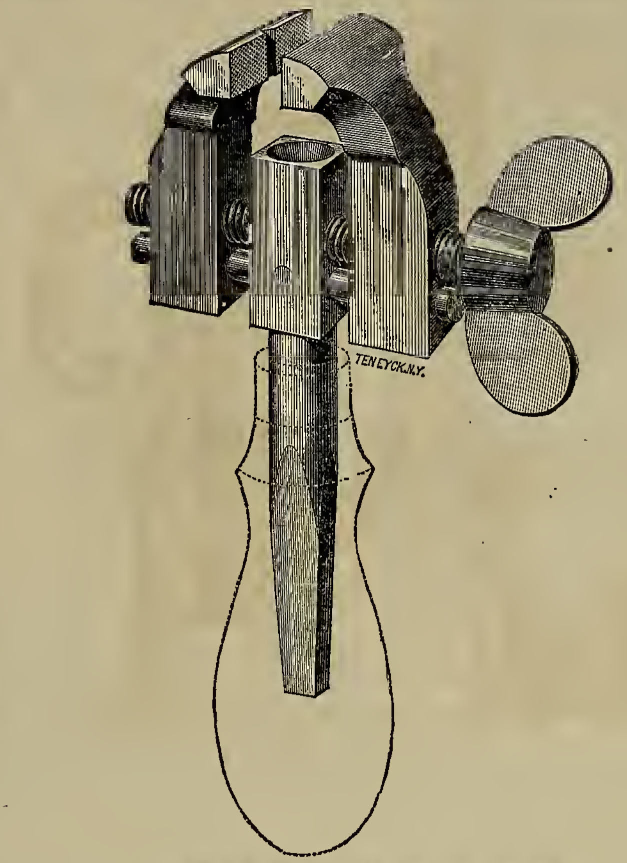
Blasting by Electricity.—A correspondent inqnires where he can obtain a suitable battery for firing blasts by electricity. We believe there is a party in this city who has several electro-magnetic machines, which he will furnish at from $10 to $50, according to power. These machines fire the charge directly by the electric spark, employing a small cartridge of fnlminating powder to ignite the principal oharge; while the galvanic batteries fire directly by converting the eleotricity into heat by means of the resistance to the current presented by a small platinum wire, which connects the main wires with the charge. The former are most convenient, requiring no chemicals, and probably, in proportion to their cost, superior in effect to the galvanic batteries, while the latter require much care and skill to keep them in order. An electro-magnetic machine of sufficient intensity for the purpose of our correspondent would probably cost $25; although a lower-priced one might possibly answer. The special oartridges reqnired for each discharge will cost about fifteen cents.

Crushing Bones.—"W. W.," of Weaver, will find some information upon the subject of his query in the agricultural department of the present issue. Mr. "W." is anxious to learn the cost of a mill suitable for crushing bones. Will some of our millmen furnish us an answer? Onr correspondent suggests the use of a stamp mill, with a single stamp weighing about 100 pounds. He thinks that would be sufficient to crush the hardest knuckle-joint. We should recommend a rotary or conical crusher; perhaps a small "rock-breaker" would answer the pnrpose of reducing them to small pieoes, to be subsequently put through a rotary crusher for reduction to a state of flour. We shonld be pleased to receive any suggestions upon this matter, which presents a good and open field to our inventors. We need a cheap and efficient bone mill. Who will fnrnish it?

The San Francisco Microscopical Society has fully organized by the adoption of a constitution and the election of the following officers: Dr. J. B. Trask, President; Gregory Yale, Vice President; H. G. Hanks, Corresponding Secretary; H. C. Hyde, Recording Secretary; E. Neustadter, Treasurer; H. G. Bloomer, Librarian. The regular meetings of the Society will be held ou the first Tuesday of each mouth.

Patent Vise and Tool Holder.

Since the introdnction into general trade of twist drills, reamers and various tools not formed with shanks for the bit brace, there has been an increasing demand for a chuck or tool holder suitable for shanks of all forms. The engraving herewith published is a very clear and accurate representation of a tool which not only meets the above demand, bnt has also many other valnable uses. It is, properly speaking, a hand vise, and as such, its parallel jaws griping the work firmly, and its wooden handle always central with the piece held, make it a most excellent and superior article. By removing the wooden handle, denoted by dotted lines in the engraving, a shank is disclosed, which may be driven into a half-inch hole in a bench or crack in a post, when it becomes a neat stationary vise for light work. By inserting this shank in a bit brace and placing the butt end of any tool in the cup at its top and turning the thumb-screw till the jaws hold it firmly, one may do any kind of boring, drilling, reaming or tapping. These are its main purposes, but the owner will find hundreds of uses for it as occasion requires. It is well made, and of the best material, and is sold at a comparatively low price. It weighs but twelve ounces, and will be a serviceable companion for travelers, as well as most ussful for mechanics and amateurs. It is called Steven's Patent Parallel-jawed Hand and Bsnch Vise and Tool Holder, and is manufactured by the inventor, W. X. Stevens, of East Brookfield, Mass., to whom applications for further information may be addressed.



STEVENS' PATENT VISE AND TOOL HOLDER.

◆

The San Bernardino Tin Mines.—The company which some months ago discovered the mines of tin about 32 miles in a northwest direction from San Bernardino have sent a lot of ore to this city to be assayed, and the results are reported to be so satisfactory that the San Bsrnardino *Guardian* says they intend at once to proceed with the development of the mine.

◆

The centennial anniversary of the founding of Monterey under the auspices of Father Junipero was celebrated on the second of the mouth in a most happy and successful manner.

Monterey.

We have room only for the following extract from the letter of our correspondent, who was present at the late centennial celebration at Monterey:

Taking passage on the steamer Senator at Santa Cruz, on this bright and beautiful morning, I was equally delighted with the excursion, and with the jovial company of Pioneers, who thought of time only for its honors, and forgot age in joyous, light-footed and careless-hearted mirth. Twenty-six miles across a bsantiful bay brought us to Monterey. The town itself is more Mexican than American in appearance, and so of its inhabitants. To thoroughly appreciate this statement, one must be conversant with Mexican towns. The hospitality of the inhabitants were sumptnous indeed, and without price.

Although its native forests are incomparable, yet but very few trees of any sort are cultivated. I saw but very little land under tillage; but the crops are all looking finely wherever cultivated. With the possible exception of grapes, every sort of choice fruit could be bountifully produced; but not one-tenth part of what is now consumed here is so produced, and not one-hundredth part of what should be used is grown about this place.

The intelligent, enterprising class of people that cultivate the soil and make homes, that render the country prosperous and the cities wealthy, have been debarred from this place by narrow, selfish, incorrigible land monopolies. The ever prosperous spirit of industrial progress, the civilizing, conquering spirit of energy has been lacking, and is still forbidden to enter and make homes for a happy people; therefore improvement, stability and general good seek other channels, and Monterey, despite her venerable age, her natural advantages of soil, climate, fine harbor, etc., is but a mean, insignificant pueblo, while her last claim to the dignity of city is about to pass away from her in the loss of the county seat, now at this place.

This is but one example of what wicked monopolists have done and are doing for this State. Its effects are not altogether local, either. The State is suffering through its length and breadth from exclusive monopolies.

The fearful drought of '63 and '64 that impoverished many individuals was a great benefit to the State by opeuing agricultural lands to the settler that had remained closed by herds of mustang stock, and would have remained so to this day had it not been for the destruction of the same. Many is the prayer offered that some condign disaster may again fall that will free every league of such lands, so that settlers can be put in honest possession. The useless, ruinous and exclusive policy now too often enforced is a curse to the conntry. And it is evident that the monopolist himself is far from satisfied or happy in his vast possessions.

S. H. Herring.

◆

A Laurel Palace.—On Tuesday afternoon the billiard rooms of the Lick House were thrown open to a number of invited guests, and were visited by quite an assemblage of ladies and gentlemen. They are fitted up in exquisite taste, with frescoed walls, velvet carpets, comfortable chairs and tables of California wood and of California manufacture. The bar-room adjoining is one of the handsomest, perhaps *the* handsomest, we have ever seen in the United States or in Europe. The California laurel certainly is a most exquisite wood for decorative purposes of the kind. In fitting up the rooms the best of taste is displayed. The proprietors, Messrs. Lewis & Woodward, have expended some $25,000 in furnishing the two rooms.

◆

The Southern Pacific Railroad Subsidy.—The election on Tuesday to determine whether San Francisco should donate one million dollars to aid in constrncting the Southern Pacific Railroad, passed off very qnietly, and excited, apparently, but very little general interest, as indicated by the fact that only 9,400 votes were cast. The proposition was dsfeated by 124 votes. It is a mattsr of surprise that so few, comparatively, voted. Last September, at the city elections, 21,404 votcs were cast.

◆

University for Women.—A New York telegram of June 8th says that, in accordance with a call signed by President Barnard, of Columbia College, President Webb, of the College of the City of New York, and other gentlemen eminent in educational matters, a public meeting was held last evening, and a project was started for the establishing of a university of the highest class for women, in that city. Rev. Drs. Thompson, Thornton and Crosby spoke in favor of the enterprise, and a committee of influential gentlemen to collect money was appointed.

◆

San Diego seems to be determined to have the matter of the Cuyamaca grant settled. It is working very injuriously to the interests of the miners to have this thing undecided, as naturally capitalists are unwilling to invest in mines which they are liable to see slipping out of their hands any day, or which may involve them in long and expensive lawsuits. It concerns not only San Diego, but also the whole State, to have such matters definitsly decided at the earliest moment.

◆

Rusting of Iron.—Dr. Calvert's experiments show that moisture and oxygen are not all that are wanted to produce oxidation. Carbonic acid must bs associated with these to produce any considerable amonnt. In dry oxygen, iron does not rust at all; in moist oxygen, but little; but in a mixtnre of moist carbonic acid and oxygen, very rapidly.

◆

Owing to long continued dry weather in France, fires in the woods have been of quite frequent occurrence of late. On June 6th a fire occurred in the beautiful forest of Fontainbleau, near Paris, sweeping over hundreds of acres. The people turned out and succeeded in checkiug the flames.

◆

Tornado in Illinois.—Last Saturday a terrible tornado passed over a portion of Scott county, Illinois, destroying orchards and crops, blowing down trees, miles of fencing, etc. No loss of lifs so far as heard from.

◆

Quartz Mill for Sale.—The attention of millmen and those wishing to purchase is directed to an advertisement on page 405 of ths preseut issue.

Ore Smelting at White Pine District, Nevada.

Editors Press:—About four years ago, when White Pine district was first discovered, detached fragments of ore, or so-called float-rock, were found from the very crest of White Pine mountain down to its base on both sides or slopes; but few veins, however, were then discovered and located, and none of these were at that time further developed than by a few days' work on each claim, as required by the mining law. It was found that those ores contained a great deal of what miners call "base metal," by which they mean all ores containing either sulphides, oxides or carbonates of iron, lead, zinc or antimony. Those ores cannot be worked by the common mill process, and consequently these mines were not looked on as at all valuable, and they laid undisturbed for a few years, until the discovery of the Eberhardt and Hidden Treasure mines, in 1868 and 1869, when thousands rushed to the new El Dorado; and as all could not be so fortunate as to find an Eberhardt mine, many turned their attention to White Pine Mountain and named it Base Metal Range. Hundreds of veins were discovered, and every stain of green, brown or blue, whether on quartz limestone or dolomite, was located.

The principal mines consisted of carbonate of lead ore, yielding by smelting process 50 to 55 per cent. of lead, and from $15 to $29 in silver. Other ores mixed with copper went generally better, some as high as $150 per ton. As to the quantity of ore, and how long it will hold out, I do not venture to say, and only time and development can tell. In the spring of 1869, the indications were such as to warrant the erection of several smelting works, with the prospect of getting ore enough for all.

The first furnace was an upright cupola, built of common country rock lined with sandstone. It was erected in what is called Sawmill Cañon, at Swansea. The blast was obtained by a common fan driven by horse-power. Several tons of ore were smelted, and then the fan burst and the horses ran away. A second attempt to run by steam-power was not more successful; the roof caught fire, the concern was burnt down, and there was an end of that establishment.

The next furnace was erected by myself at Swansea, at what is now known as the White Pine Smelting Company's Works. The first furnace was an upright-shaft furnace, of a trapezoidal shape inside, being twenty-four inches in the clear and twelve feet high. The lining was made of a fire-proof sandstone found close to the furnace. The air was supplied from a Root's blower, driven by a four-cylinder engine capable of driving four such blowers. The second furnace was of double the size of the first, and built of the sandstone heretofore mentioned, cut in blocks twelve inches thick, and well bound with iron. It needs no further outside shell or wall to keep it together. This furnace ran through about fifteen tons of carbonate of lead ore from the Miser's Dream mine, which yielded 55 per cent. of lead and about $30 in silver. A small addition of clay or loam answered as a flux. The charcoal used was of the best quality, made from mountain mahogany and nut pine. About fifteen to twenty bushels were used to the ton of ore, and cost, delivered at the works, thirty cents.

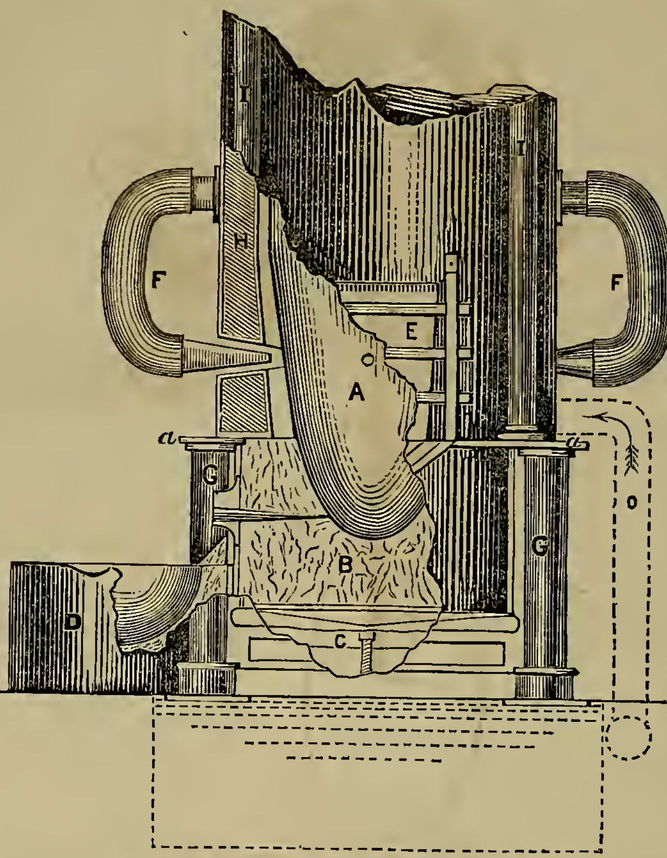
These smelting works were built in a substantial and workmanlike manner, at a cost of about $20,000, and have so far proved a practical success and a benefit to the miners, as hundreds of tons of ore have been purchased and reduced in them. During the last twelve months at least forty furnaces have been erected of various shapes and styles, but, as far as I know, they all have failed, and especially the reverberatory furnaces. The continual trouble was that the bottom burned out or cracked, and the metal leaked through. In most cases it was more the incompetency of the proprietors and smelter than the fault of the fire-proof material. They had the same as we used. Another blast furnace has recently been started at Hamilton, and ran about thirty days, and was considered a great success. The amount of fuel they used I cannot state.

The advantage of a blast furnace for smelting ore is, that more heat is utilized than in a reverberatory. In England, where coal, as for instance, in Swansea, is only five shillings per ton, it is of less consequence if they lose one-half the heat or more; but in White Pine, where charcoal costs two cents per pound, we have to study the most economical plan. Besides, to build reverberatories to reduce fifteen tons per day costs four times what it does to erect a single blast furnace of the same capacity.

I will now state the defects and difficulties to be encountered in running an ordinary brick or stone furnace, and will also show how these defects can be overcome.

The first trouble is, with regard to the hearth or bottom, which is commonly made of clay and charcoal rammed into the solid brickwork and then cut out to the desired shape. It is allowed gradually to dry and then heated up gently for a day or two to drive out the moisture. If this is not done or the furnace is heated up to soon, the metal begins to boil and the whole mass often gets cracked or porous, the metal penetrates it and soon will leak out wherever it finds an outlet, or it impregnates the surrounding bricks or stone to a very great extent. Thus I found lately in a furnace bottom, which had been used for some time, several tons of metal diffused throughout the sandstone, which was so solidly cemented together by the lead that it took ten days to cut it out. This is not only expensive but delays the repairing for at least two weeks, and the metal is nearly all lost, as it will not pay to smelt the penetrated sandstone to get out the lead. Solid stone or fire-proof brick hearths have also been tried, but they are entirely impractical. We have no better material than clay or charcoal in certain proportions, and if that be used carefully and rammed on a very solid foundation, in many cases it will last for a long while. Since writing the above, I have heard of an explosion having taken place in one of the furnaces at White Pine, which knocked out the front and rear. It was attributed to starting the furnace before it was sufficiently dry.

The second trouble is the burning out of the lining around and above the tuyeres This is generally effected by the overheating of the charge. I have not yet seen on a clay furnace a pressure gauge. As a general rule, a larger blower is used than is actually needed to supply the requsite amount of air, and the driving power is often run twice as fast as at other times, and of course gives an unsteady blast. Most of the furnaces erected have not been built by men who have studied metallurgy, and people do not want anyone who knows the business as a profession, because one or two Freiberg students have made blunders. They condemn them all, and rather take unexperienced men and spend four times as much in experiments, as is necessary.



PLAN FOR CONSTRUCTING A SHAFT FURNACE.

An experience of fifteen years in smelting leads me to propose a new plan for the construction of blast furnaces, which I think can be extensively used with profit in our mining districts in many cases, and which will be understood from the annexed drawing and description.

The upper part of the furnace is constructed of masonry in any proper manner. That part, however, where the greatest heat is produced, consists of a wrought-iron shell, H, which acts as an air-chamber, and also for the protection of the lining of the furnace. The air as it comes from the blower passes through the pipe, o, into this shell, keeping it cool, and thence through the tuyeres, F, into the furnace. This shell rests on an iron plate, *a*, supported by four posts, G, one at each corner. The upper part of the furnace is also supported independently on iron posts, I. The shaft is lined inside with about three inches of fireclay, for the protection of the iron. If preferred, water may be used instead of air for cooling the shell. The bottom or hearth of the furnace is movable. It is made of strong boiler iron, either round or square, and is filled with the material used at present at White Pine, pounded down and cut into shape. It can be run in and out on wheels, and firmly secured in place by screws or similar contrivances. It will be of advantage to have constantly on hand an extra hearth, so that when the one in use burns out, it can be replaced very quickly by a fresh one. The expense of building such a furnace will not be one-half of that required for brick structures, while it will last longer and can be put up in two days. The ironwork costs in San Francisco less than five hundred dollars, and adding to this the expense of freight and lining, the total will not be over $700.

The improvement of a movable hearth can also be applied to furnaces already constructed of brickwork or to Haskell's water-lined, and for reverberatory furnaces.

In the next I will give you the description of what I consider an improvement of great value applicable to reverberatory and other furnaces where much heat is lost. The waste heat, amounting in some cases to three-fourths of that used, will all be returned to the fireplace.

J. Mosheimer.

The Yosemite Claim.—A telegram from Washington, under date of June 6th, states that the Senate Committee on Public Lands report adversely on the bill granting a portion of the Yosemite valley to Hutchings & Lamon, which is considered equivalent to a rejection of the bill.

A Full List of Patents Issued to Pacific Coast Inventors.

[From Official Reports to DEWEY & CO., U. S. and Foreign Patent Agents, and Publishers of the Scientific Press.]

For the Week Ending May 31st.

Carriage and Railroad-Car Wheels.—Almond F. Cooper, San Francisco.

Tongs for Rigging.—George Dohn, Sacramento, Cal.

Percussion Fuse.—William Gardner, San Francisco.

Method of Distilling in Vacuo.—Frederic Gutzkow, San Francisco.

Tension-Wheel for Sewing Machine.—John H. Mooney, San Francisco, Cal., assignor to Samuel Hill, same place.

Wheel-Carriage Seed-Sower.—John H. Cole, Vacaville, Cal.

Excavating Machine.—Andrew W. Hansen, Stockton, Cal.

Nut-Locking Washer.—Robinson Rutter, Vallejo, Cal.

REISSUE.

Needle for Sewing Machines.—Mary P. Carpenter, San Francisco, Cal.—Patent No. 99,158, dated January 25, 1870.

Note.—Copies of U. S. and Foreign Patents furnished by Dewey & Co., in the shortest time possible (by telegraph or otherwise), at the lowest rates. All patent business for Pacific coast inventors transacted with greater security and in much less time than by any other agency.

* * *

Lake County Items.

The Lower Lake *Bulletin* makes reference to the industrial interests of Lake county, from which we condense as follows:

Quicksilver.—The quicksilver mines on the Knoxville road appear to be progressing as usual. The Redington Quicksilver Company reduced the wages of many of their hands the first of April. The new furnace at the Manhattan mine is undergoing some alteration. The Reed mine is to be opened shortly and a force of men put on.

Borax.—The California Borax Company have their lands rented out to stock ranchers; the waters in the lake has not yet fallen sufficiently for a re-commencement of work. At the Little Borax Lake everything wears a favorable appearance, quite a lot of borax being on hand ready for shipment.

Sulphur.—The sulphur works have stopped for a time, as they already have several months hauling of sulphur on hand.

Springs.—Among the places of summer resort, the Seigler Springs stands prominent. These springs are a natural curiosity in their way; water hot, cold and chalybeate, springing forth within a circle of a few hundred yards, and affording opportunities for bathing unrivalled elsewhere upon the coast.

Marble and Lime.—A marble quarry has recently been discovered in Morgan Valley. The lime quarry in that neighborhood supplies the surrounding country with a better quality of lime than can be found elsewhere in the State.

The Farming Interest.—There is a promise of abundant crops. The grain crop of Lake county will exceed the crop of any previous year. Roads, however, are needed, and a farming population that will work and develop their own lands. The *Bulletin* says: "We have too many farmers who seem content to eke out a bare subsistence from year to year, whose buildings and farms can hardly be called improvements, and whose thriftless mode of conducting their farms rather tends to depreciate than enhance the value of them. This class of individuals invariably ask the highest price for their land, as they are well aware that it is their only means of ever making anything out of them. The result of having a superabundance of these people in any community is, that valuable lands lay unimproved, worthless alike to the owners and to the State, for the former hold the property for a speculative price without enhancing its value by improvement or cultivation, save to a very limited extent. They are, in fact, speculators, as they are evidently not producers, and, in common with all speculators or speculative objects, to be of any public benefit, should be assessed and taxed in the same proportion to their speculative value that is adopted in the assessment and taxation of other property whose value is fixed and settled."

Constantinople has been visited by another conflagration. Several thousand houses were destroyed and over thirty lives lost, and at last accounts the fire was still unsubdued.

Professional Cards.

Metallurgy and Ores.

MINING SCHOOL.
Mosheimer's Practical Mining School
Will be reopened by the FIRST OF JUNE, and practical instruction given in all branches of Assaying, Crushing, Amalgamating Concentrating, Smelting and Refining Ores; also Erecting Furnaces and Reduction Works of every kind. To give all miners a chance to learn Assaying of Ores (what everyone ought to) I have reduced my former charge for

Assaying Ores..............................	$ 50.00
To work Gold and Silver Ores....................	100.00
Smelting and Refining, including Assaying......	150.00

Many gentlemen who have been taught in my establishment will bear testimony that in a few days they learned more than they expected to learn in a month. Before going into mining, every man ought to know how to test ores, and then he will go to work with prudence and never fail to be successful. Apply to
J. MOSHEIMER,
Office, 328 Montgomery street; Works, 2,005 Powell street, San Francisco. 22v23-3m

A. T. GREEN,
COMMISSION MERCHANT,
No. 3 Front Street, San Francisco.
Agent for SAMPLING, CRUSHING, ASSAYING and SELLING OF ORES Shipments received from miners, and the entire business transacted with promptness and accuracy. MERCHANDISE of all descriptions purchased and shipped on Commission for Country Merchants. Consignments of PROVISIONS received and sold at the highest market prices.
Refers, by permission, to Jas. Linforth, of Linforth, Kellogg & Co.; Jona. Hunt, Prest. Pacific Insurance Co.; A. J. Ralston, Sec. Pacific Insurance Co.; Jos. A. Donohoe, of Donohoe, Kelly & Co.; Falkner, Bell & Co.; Badger & Lindenberger; Taaffe & Co., and J. B. Roberts, Esq. 23v20-3m

MORRIS & WHITE,
Practical Assayers and Metallurgists,
No. 30 and 36 Fremont Street,
SAN FRANCISCO.

Ore of all kinds worked by Pan Amalgamation, Chlorination, or Smelting—guaranteeing to work as close to the Fire-assay as any persons on the Pacific Coast.
☞Gold and Silver Ores and Sulphurets bought.

NEW EDITION

—OF—

507 MECHANICAL MOVEMENTS.

PUBLISHED BY

DEWEY & CO.

LIST OF CONTENTS.

Æolipile.
Balance, Compensation: Barometer; Blower, Fan; Brake, Friction.
Cams; Capstans; Centrolinead; Clutches; Chasers; Clamps, bench and screw; Cock, four-way; Column, oscillating; Compasses, proportion; Counters of revolutions; Coupling, union; Crank—substitute for the, variable; Cranks, bell and compound; Cyclograph.
Differential Movements; Brag-link; Drill—Fiddle and Persian; Drills, Cramp; Brop; Brum and Rope; Driver, Pile; Dynamometers.
Eccentrics; Ejectors, Bilge; Ellipsograph. Engine, Bisk; Engines—Rotary, Steam, Valve Gear for; Epicyclic Trains; Escapements.
Fountain, Hiero's; Fusees.
Gasometers; Gauge, Bisecting; Gauges, Pressure; Gear, Steering; Gearing—Bevel, Brush, Capstan, Conical, Crown, Eccentric, Elliptical, Face, Friction, Internal, Irregular, Multiple, Mutilated, Scroll, Sector, Spur, Step, Stud, Sun and Planet; Gearing—Variable, Worm; Governors; Guides; Gyroscope.
Hammers - Atmospheric, Bell, Compressed Air, Trip, Steam; Helicograph; Hook—Boat-detaching, Releasing; Hooks, Centrifugal Check; Hyperbolas, Instrument for Drawing.
Intermittent ovements.
Jack—Hydrostatic, Lifting; Joint—Ball and Socket, Bayonet, Universal.
Ladder—Folding, Self-Adjusting; Lazy-tongs; Level, Self-recording; Lever—Bell-crank or Elbow, Knee; Lewis; Link Detachable Chain.
Machine—Bohnenberger's, Brilling, Polishing, Punching, Warp-dressing; Main, Flexible Water; Maintaining Power; eter—Gas (wet and dry), Water; ill—Barker's, Crushing, Tread, Wind; Miscellaneous ovements; otion—[illegible] rusting Traverse, Rocking, Self-reversing, Shuttle; Motions—Feed, Link, Parallel, Pump, Traverse, Variable Traverse.
Pantograph; Parabolas, Instrument for Brawing Paradox, Mechanical; Pendulum, Conical; Pendulums, Compensation; Pinion—Lantern, Mutilated, Slotted, Two-toothed; Power, Horse; Presses, Hydrostatic; Propeller, Screw; Pulley—Expanding, Friction; Pulleys—Anti-friction Bearing for, Chain; Pump—Air, Balance, Bellows, Chain, Diaphragm, Steam-siphon; Pumps—Bouble-acting, Force, Lift, Rotary; Punching Machine.
Rack—Mangle, Mutilated; Racks and Pinions; Ram, Montgolfier's Water; Ratchets and Pawls; Regulator—Gas, Watch, Reversing Motion, Self; Revolver; Rollers, Oblique; Rolls—Anti-friction, Brawing, Feed; Rulers, Parallel.
Saw—Endless Band, Gig, Pendulum; Screw, Archimedes, Bifferential, Bouble Reversed, Micrometer; Screws—Endless, Right-and-left Hand; Sectors; See-saw; Shears; Stamps; Stand, Mirror; Stop—for Hoisting Apparatus, for Lantern Wheels, for Ratchet Wheels, for Spur Gear; Stops for Winding Watches.
Test, Friction; Throttle, Spinning; Toggle-joint; Tongs, Lifting; Trap, Steam; Treadles.
Water, Machines for Raising: Weir, Self-acting; Wheel Cam, Lantern, Persian, Pin, Rag, Sprocket, Steering, Waved; Wheels—Crown, Mangle, Paddle, Water; Windlass—Chinese, Friction; Windmills; Wipers.

This book is bound in cloth, and embraces 122 pages. The illustrations are plain, and each figure is clearly described on the page opposite to it. It is a low-priced book for its kind, and there are few persons who have to do with machinery, or are interested in understanding the science and principles of motion, who will not be benefitted and satisfied by its purchase.

A liberal discount made to the trade. Single copies, $1—sent postage free. Address orders,

THE NEW AGE,

A Weekly Journal of Sixteen Pages.

The "Official Organ" of the I. O. O. F. on the Pacific Coast.

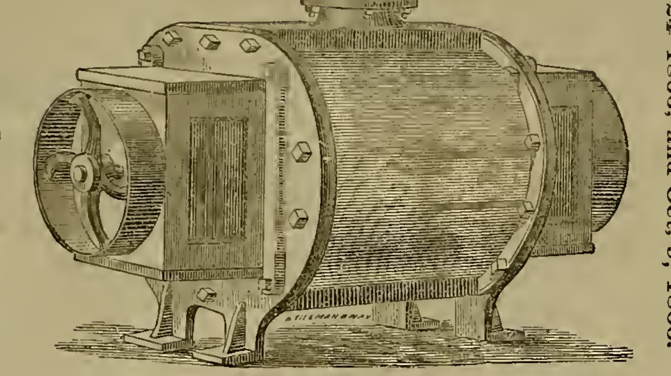
Is devoted to Odd Fellowship, the Arts and Sciences and General Literature; and as a family paper is not surpassed by any journal in the United States. Subscription price per year by mail, $5. Belivered in the city, per month, 50 cents. Office, Odd Fellows' Hall, 327 Montgomery street, San Francisco. 19v19

ROOT'S PATENT FORCE BLAST ROTARY BLOWER.

MANUFACTURED BY KEEP & BARGION,

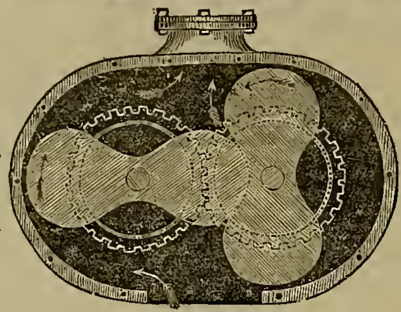
At the Globe Iron Works, Stockton, California.

Awarded the First Premium at the Paris Exposition.



Patented Nov. 1st, 1864; July 24 1866; and Oct. 9, 1866.

ADAPTED FOR Smelting, Foundry, Mining and Steamships.



REQUIRES Fifty Per Cent. LESS POWER Than any Blower Now in use.

One of these Blowers may be seen on exhibition at W. T. Garratt's Brass Foundry, corner of Mission and Fremont streets. They are also in use at the Almaden Quicksilver Mine; Gridley's Foundry, Gold Hill, Nevada; Ætna Iron Works, San Francisco, and many other places.

Caution.—Purchasers will find it to their advantage to apply direct to the Stockton Agency. as certain parties, not authorized to manufacture the Blower, have put in the market machines of inferior construction, which do not answer all the requirements of the genuine article.

Quartz, Saw and Grist Mill Irons, Steam Engines, Horse Powers, High and Low Pressure Steam Engines, Steamboats and Propellers, made at short notice.

For circulars and further information, address

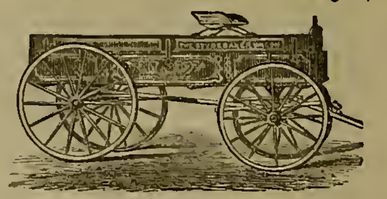
Scientific Press.—Bewey & Co. are the publishers of this sterling paper It is devoted to the dissemination of mining, farming and scientific knowledge, besides containing miscellany of interest.—*Monterey Republican*

The Celebrated Studebaker Wagon,



Manufactured by STUDEBAKER BROS MANUFACTURING CO., South Bend, Indiana. WAGON DEALERS, there are nine reasons why you should buy the above Wagon:

First.—They are made of the best selected INDIANA TIMBER, thoroughly seasoned under cover.

Second.—They are made by experienced mechanics.

Third.—The lightest running and most durable Wagon in the market.

Fourth.—Their Thimble Skeins never break, while all others do.

Fifth.—Most uniform and best proportioned Wagon in the market; any part of one will fit another, while other makes will not

Sixth.—The only Wagon in which the Slope Shoulder Spoke is used; hence they have the best Wheel, which is actually the foundation of the Wagon, and should be carefully examined by persons buying.

Seventh.—They are sold only by responsible parties, and every Wagon is warranted to give entire satisfaction.

Eighth.—Because Teamsters will tell you they are the best Wagons, for all purposes, on the road.

Ninth.—Last, but not least, Studebaker Brothers are practical men, attend to their business personally, and do not entrust it entirely to foremen, as is generally the case in large factories; hence the superiority of their work over all others. Sold by

COPELAND & DEFREES,

New Incorporations.

The following have filed certificates of incorporation with the County Clerk, San Francisco:

California Immigrant Association.—May 26th. Object: To encourage immigration from Europe to California. It has no capital stock. Principal place of business, this city; duration, 50 years. Directors: A. Austin, W. E. Eichelroth, Adolph Muller, G. Holland, L. C. Gunn, W. H. Clary, Thomas Wallace, Geo. Claussenis, H. W. Fortune, Geo. Eidenmuller, E. V. Sutter, B. Sharboro, Geo. D. Roberts, Herman G. Muller and John B. Felton.

Pacific Wire and Wire-Rope Manufacturing Co.—May 27th. Object: To engage in and carry on the business of manufacturing metals, wires, wire-ropes, telegraph cables, and other products, and selling the same. Capital stock, $100,000, in 1,000 shares. Trustees: A. S. Hallidie, Jonathan Kittredge, Robert Watt, Joshua Gray, David Farquharson, Charles F. Marwedel and Edward Kruse.

Confidence Co.—May 31. Object: To mine for gold and silver on the Confidence ledge in Tuolumne county, State of California. Capital stock, $800,000; divided into 8,000 shares. Trustees: Ben. Holliday, Jesse Holliday and William Norris.

Zeile Mining Co.—June 3d. Capital stock, $100,000; divided into 1,000 shares. Trustees: Frederick Zeile, John Zeile and Solomon Heydenfeldt.

Jennie A. Consolidated M. Co.—June 4th. Capital stock, $2,200,000, divided into 44,000 shares. Trustees: T. W. Mulford, J. E. Purdy, E. M. Smith, T. R. Horton and T. L. Fitch.

The following have been recorded in the Secretary of State's office, Sacramento:

Sacramento City Railroad Co.—May 26th. Directors: N. D. Thayer, George W. Chesley, P. H. Russell, H. F. Hastings, J. C. Garland, Robert Hamilton and E. G. Robinson.

Noyo River and Round Valley R. R. Co. May 26th: The proposed road is to run from the mouth of the Noyo River, in Mendocino county, to Round Valley, in the same county, a distance of forty-five miles. Capital, $150,000; divided into 1,5000 shares. Directors: S. W. Gloserer, E. Janisen, C. C. Gurnee, Thos. W. Moore and R. Stretch.

San Diego Banking Co.—June 3d. Capital stock, $100,000. Trustees: A. E. Horton, Bryant Howard, Mathew Sherman, Joseph Nash, E. M. Morse, A. H. Hathaway, W. H. Cleveland, Columbus Dunham and James M. Pearce.

National Tin M. Co.—June 3rd. Capital stock, $10,000,000. Trustees: Chalmers Scott, R. C. Brown, Ward Bradford, J. P. Abbott and A. H. Gilbert. Principal place of business, San Diego.

Meetings, Elections, Etc.

Steam Navigation Co.—May 23d. Trustees: B. M. Hartshorne, W. H. Taylor, A. Redington, A. Hayward, Lloyd Tevis, S. F. Butterworth, W. C. Ralston, John Bensley and William Alvord.

Humboldt Savings and Loan Society. May 26th. Directors: Adolph C. Weber (President), E. D. Keyes (Vice President), John Wieland, Joseph Frank and David Porter; Treasurer, A. Gansl; Secretary, A. Hartman; Attorney, Julius George.

Ascendant M. Co.—June 6th: Trustees: L. L. Alexander (President), Albert Shephard (Vice President), R. A. Robinson, L. B. Drew, and D. McLaren (Secretary).

Silver Wave M. Co.—June 6th. Trustees: D. W. Folger, E. W. Woolsey, J. E. Perkins, W. P. Pritchard and E. F. Hall, Jr.

Mammoth S. M. Co.—June 6th. Trustees: John Sime, Nathaniel Page, S. Linkton, George Congdon, Alfred Wheeler, Otis V. Sawyer and J. W. Winter. At a meeting of the Board, the following officers were chosen: President, S. Linkton; Vice President, George Congdon; Treasurer, B. F. Hastings; and Secretary, Joseph L. King.

Bromide Tunnel Co.—June 6th. Trustees: J. E. de la Montagnie (President), O. Dickinson, Jr., C. W. Kellogg (Vice President), N. C. Efford, F. S. Weeks and Charles Lambert. Henry Boyle was reappointed Secretary.

Paul Tract Homestead Association. June 6th. Trustees: Louis Gerstle, H. A. Crane, M. L. Citron, C. D. Wheat, F. B. Wilde, A. B. Stout and James E. Damon. Following are the officers chosen: President, H. F. Williams; Vice President, S. Arnheim; Treasurer, W. C. Ralston; Secretary, F. B. Wilde.

Crown Point M. Co.—June 6th. Trustees: J. D. Fry (President), A. Hayward, Robert Sherwood, A. K. P. Harmon and H. C. Kibbe. C. E. Elliott was elected Secretary, and J. Jones, Superintendent.

California Silk Manufacturing Co. June 7th. Trustees: James T. Dean (President), R. O. Page, T. H. Purvis, J. D. Johnston and James Milburn (Secretary).

New Mexico Mining Items.

The New Mines—A correspondent of the Boise City *Statesman* writes April 29th from Ralston, Grant county: I will venture the assertion that the half has not been told, both as to cubic yards and pounds troy. No mine that has ever been discovered within this country or South America bears any resemblance. Imagine a ledge of fine milling rock standing perpendicularly above the surface for thousands of feet in length without a break—ten to two hundred feet wide, and above the surface sixty feet in height—and you have some idea of these mines."

Somebody at Fort Bayard writes April 25th to his dear uncle in San Francisco: "I have struck it at last. These mines are near Apache pass, six miles from Barney Station, on the direct route from Tucson to Santa Fé. I easily get by smelting 32 cents per pound—$640 per ton—from my rock. I am on the main lead, and on a half a dozen more. Two hundred feet I have for *you*. White Pine is poor in comparison. If one half of what California sharps say is true, $500,000 wouldn't buy me out."

◆

Intelligence of Fishes.—A writer in a recent English work, "The Angler and Naturalist," says: That fish are not so stupid as many people suppose, is proved by a little incident which was observed at the Zoological Gardens. In some plate-glass tanks were a pike and several perches. These fishes took no notice of our entrance, and continued perfectly supine, though the keeper walked several times past their tanks, as if about to feed them; but when he walked away from them toward the cupboard where the net, with which the baits were caught, was kept, the stolid demeanor of the fish, both pike and perch, gave way to the most intense excitement. They rushed to and fro across their enclosures, straining their noses against the glass, erecting their fins, and exhibiting every token of agitation; and when the keeper, having taken the net, proceeded with it toward the bait tank, the whole shoal fastened their eyes upon him, following every movement, and constantly veering round, as if under magnetic attraction, toward whichever part of the room he turned. It was evident that these fish knew where the net was kept, that the keeper was going to fetch it, and that his doing so was a preliminary to their being fed.

To Print on Fruits.—When a handsome fruit is intended to be shown at a fair or sent to a friend, it will add something in the way of novelty to have its name or that of some person printed indelibly upon its surface. This may be done in several ways, but the most common methods are as follows: Just before the fruit has attained its maturity, cut from tough, thin paper the name proposed and paste this upon the side of the specimen most fully exposed to the sun. That portion of the fruit covered by the paper will assume a different color from the other, and when ripe the paper is removed, leaving the name distinctly visible. Upon squashes and melons, names and figures may be indelibly impressed by slightly scratching the surface while they are growing.

The Gypsies in the Hop-Garden, in Pesth, have a curious way of looking after the honesty of their money collector. The person entrusted with the mission of taking the hat round among the crowd has a living fly put in his left hand, while he holds the hat with his right. When he returns with the funds he must bring the fly back alive, as a sign that he has not taken any money from the common property; but if the fly be wanting, or even dead, he does not get his share of the money.

Remedy for Ear-ache.—M. Duval says he has found relief in severe ear-ache, other means failing, from a mixture of equal parts of chloroform and laudanum, a little being introduced on a piece of cotton. The first effect is a sensation of cold, then numbness, followed by a scarcely perceptible pain and refreshing sleep.

Heavy shipments of wool and furs, from Utah and other Western Territories, are being made to the East. A number of cars so loaded passed through Omaha last week.

Our Agents.

Our Friends can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

☞ Maravilla Cocoa.—*For Breakfast.*—The *Globe* says: "Various importers and manufacturers have attempted to attain a reputation for their prepared Cocoas, but we doubt whether any thorough success has been achieved until Messrs. Taylor Brothers discovered the extraordinary qualities of 'Maravilla' Cocoa. Adapting their perfect system of preparation to this finest of all species of the Theobroma they have produced an article which supersedes every other Cocoa in the market. Entire solubility, a delicate aroma, and a rare concentration of the purest elements of nutrition, distinguish the Maravilla Cocoa above all others. For homœpaths and invalids we could not recommend a more agreeable or valuable beverage." Sold in packets only by all Grocers, of whom also may be had Taylor Brothers Original Homœopathic Cocoa and Soluble Chocolate. Steam Mills—Brick Lane, London. 5v20-1y

To Miners, Millmen and Metallurgists. Kustel's new work on the Concentration of all kinds of Ores, and the Chlorination Process, for Gold-bearing Sulphurets, Arseniurets, and Gold and Silver Ores generally, is the best and most complete work issued. It contains 120 diagrams, illustrating machinery, etc., which alone are of the greatest value. Price, $7.50, postage paid. Published by Dewey & Co., publishers of the Scientific Press, San Francisco.

It is a great thing for elderly persons to have their fading eyesight restored to its youthful perfection. This can be done by Muller, who is recognized as the optician of the Pacific coast. His Brazilian spectacles, properly fitted and adjusted, are superseding all others in use. *

Attention to Mining Companies of Copper and Galena Ores.—A mining engineer and assayer thoroughly acquainted with practical smelting of lead and copper ores, and competent to put up all kinds of furnaces, wishes employment. References given Please address C. T. MOHRIG, care of Schultz, Fischer & Mohrig, No. 10 Stevenson street, near First, San Francisco. 23v20-1m

We call attention to the new portable gas burner—the only one that can be regulated to any size, flame, and burn without smoke or smell. Equal to any gas at one-fourth the cost. P. J. Philipa & Co., 550 Market street, have county rights for sale for this valuable invention; also lamps for sale. No one should be without them who wants a good, cheap and safe light. 21v20-4w

Inquire Within.—The mouth is like a house to let. However pretty it may be externally, it is impossible to judge of its merits until you have seen the inside. If behind the ruby doors there are plenty of pearl-white fixtures, you will exclaim at once, "How beautiful!" To impart the utmost possible brilliancy, there is nothing like fragrant Sozodont. *

"Spalding's Glue" mends everything. *

Treatment of Rebellious Silver Ores, by Charles H. Aaron—a pamphlet of eight pages of concise reading, of practical value to parties interested in the subject. Printed and sold by Dewey & Co., at this office, for 25 cents, post paid.

Business Fortunes are often made easily, quickly and legitimately by Patent Rights. We advise both sellers and purchasers to patronize reliable agents only. Weister & Co., patent brokers, No. 314 Bush street, San Francisco, are one of the most honest, reliable firms in the United States. *

Brooklyn, Cal., May 31st, 1870.
Messrs. Dewey & Co.—Dear Sirs—Accept my thanks and congratulations for your prompt and efficient measures in securing the approval of my claims. Yours, very truly, A. H. Banole.

To Farmers.—Stevens & Bro's Egg Boxes, holding 30 dozen, supplied free of charge, by John Gray & Co., No. 210 Clay street, San Francisco, to all customers. The eggs are kept cool and free from moisture and mould, are in no danger of being broken, and require no recounting. 20v20-3m

Photography.—For Cabinet Photographs, or Enameled Cards, of the very best quality, you must go to the NEW YORK GALLERY, Nos. 25 and 27 Third street, San Francisco. Every picture warranted to give satisfaction.
10v18 5m B. F. Howland.

Mason's Bread of Life, for Dyspeptics, Coughs, Colds, Asthma, Catarrh, Hoarseness, Bronchitis and Sore Throat. Price, 25 cents per box. These lozenges are free from all dangerous properties. Compounded and put up by Dr. J. H. Mason, 750 Howard st. 16v20-3m

Continental Life Insurance Co., 302 Montgomery street, corner of Pine.

New Mining Notices.

Cordillera Gold and Silver Mining Company, Chihuahua, Mexico.

Notice is hereby given, that at a meeting of the Board of Trustees of said Company, held on the eighth day of June, 1870, an assessment of fifty (50) cents per share was levied upon the capital stock of said Company, payable immediately, in United States gold coin, to the Secretary, at his office, No. 321 Washington street, San Francisco, California.

Any stock upon which said assessment shall remain unpaid on Saturday, the ninth day of July, 1870, shall be deemed delinquent, and will be duly advertised for sale at public auction, and unless payment shall be made before, will be sold on Monday, the first day of August, 1870, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Trustees.

HENRY R. REED, Secretary.
Office, 321 Washington street, San Francisco. jul1

Latawana Mining Company—Near Hamilton City, White Pine, State of Nevada.

Notice is hereby given, that at a meeting of the Board of Trustees of said Company, held on the second day of June, 1870, an assessment of fifteen cents per share was levied upon the capital stock of said Company, payable immediately, in United States gold and silver coin, to the Secretary, at 614 Merchant street, Room 26, San Francisco, California

Any stock upon which said assessment shall remain unpaid on the fourteenth day of July, 1870, shall be deemed delinquent, and will be duly advertised for sale at public auction, and unless payment shall be made before, will be sold on Saturday, the sixth day of August, 1870, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Trustees.

A. MARTINON, Secretary.
Office, 514 Merchant street, Room 25, San Francisco, California. jul1

Nevada Land and Mining Company.—Location of Works: Steptoe, Johnson & Latham, Antelope and Clifton Districts, Elko County, State of Nevada.

Notice.—There are delinquent upon the following described stock, on account of assessment levied on the third day of May, 1870, the several amounts set opposite the names of the respective shareholders as follows:

Names.	No. Certificate.	No. Shares.	Amount.

And in accordance with law and an order of the Board of Trustees, made on the twenty-ninth day of April, 1870, so many shares of each parcel of said stock as may be necessary will be sold at public auction, at the office of the company, room No. 5, No. 302 Montgomery street, San Francisco, Cal., on Tuesday, the twenty-first day of June, 1870, at the hour of one o'clock P. M. of said day, to pay said delinquent assessment thereon, together with costs of advertising and expenses of sale.

WM. H. WATSON, Secretary.

Office, Room 5, 302 Montgomery street, S. F. jc 4

Evening Star No. 1 Silver Mining Company.—Location of Works: White Pine County, State of Nevada.

Notice is hereby given, that at a meeting of the Board of Trustees of said Company, held on the first day of June, 1870, an assessment of five (5) cents per share was levied upon the capital stock of said Company, payable immediately, in United States gold coin, to the Secretary, at the office of the Company, Room 5, No. 302 Montgomery street, San Francisco, California.

Any stock upon which said assessment shall remain unpaid on Saturday, the second day of July, 1870, shall be deemed delinquent, and will be duly advertised for sale at public auction, and unless payment shall be made before, will be sold on Monday, the twenty-fifth day of July, 1870, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Trustees.

WM. H. WATSON, Secretary.

Office, Room 5, No. 302 Montgomery street, San Francisco, California. ju4

Marcelina Mining Company.—Location of Works: Eureka Mining District, Lander County, Nevada.

Notice is hereby given, that at a meeting of the Board of Trustees of said Company, held on the nineteenth day of May, 1870, an assessment of forty (40) cents per share was levied upon the capital stock of said Company, payable immediately, in United States gold coin, to the Secretary, at 325 Sansome street, San Francisco.

Any stock upon which said assessment shall remain unpaid on Thursday, the twenty-third day of June, 1870, will be advertised on that day as delinquent, and unless payment shall be made before, will be sold on Tuesday, the nineteenth day of July, 1870, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Trustees.

C. O. PALMER, Secretary.

Office, 325 Sansome street, San Francisco. m28

The large majority of United States and Foreign Patents granted to inventors on the Pacific coast during the past few years, have been obtained through the agency of Dewey & Co., publishers of the Scientific Press. Established in the year 1860, we have an extensive patent library, with full record of cases on this coast, and can give the best and most reliable advice as to the patentability of new inventions.

One Per Cent. per Month

Allowed on Six Months' Deposits by the CALIFORNIA BUILDING, LOAN AND SAVINGS BANK, California street, one door from Sansome.

THOMAS MOONEY, President.

Sheffield Scientific School

Of Yale College, New Haven, Conn.

This department of Yale College, instituted in 1840, and endowed with the National Land Grant in 1866, furnishes advanced instruction in the various branches of Mathematical, Physical, and Natural Science.

The School is under the direction of the President of the College, a Board of thirteen Professors in different specialties, and six assistant instructors.

Regular courses of study, leading to the degree of Bachelor of Philosophy, conferred by Yale College, are arranged as follows: 1—Chemistry and Mineralogy. 2—Civil Engineering. 3—Mechanical Engineering. 4—Mining Engineering and Metallurgy. 5—Agriculture. 6—Natural History and Geology, and 7—Select Course.

Advanced students are also admitted to optional courses, and if already College graduates, are received as candidates for the degree of Doctor of Philosophy.

Tuition, $125 per year of forty weeks.

The Libraries, Museums, Laboratories and Apparatus accessible to students, are varied and extensive.

For copies of the Annual Circular and Report, letters may be addressed to the "Secretary of the Sheffield Scientific School." New Haven, Conn. v18-1y15p

TARRANT'S SELTZER APERIENT.

A Blessing Infinitely Multiplied.—The discovery of the Seltzer Spring has been a blessing to thousands; but the extension of its medicinal benefits to the whole civilized world through the medium of Tarrant's Effervescent Seltzer Aperient is a boon which no form of words can adequately describe. It is as if millions upon millions of Seltzer Springs—branches of the parent fountain, and in all respects the same—had sprung up spontaneously everywhere, annihilating dyspepsia, strengthening the debilitated, curing biliousness, abating fever, purifying the blood, cheering despondency, and diffusing health and hope far and wide. Such are its happy effects.

SOLD BY ALL DRUGGISTS.

CHOICE POULTRY.

Light Brahma and White Leghorns.

We are now booking orders for a few trios of the above named fowls, bred from choice imported stock. Will commence delivering in July. All orders filled in rotation, as received.

☞ A few clutches of eggs for setting from the above named breeds.

Greatest Discovery Ever Made.
MR. J. W. MAC, while a resident in New Zealand, was so afflicted with the RHEUMATISM, that for years he was completely crippled and unable to attend to business. The symptoms were of the worst type—knees painful and swollen, with sinews contracted; shoulder, arm and hand rendered useless, and accompanied with continued excruciating pain. While in this state of suffering, he got acquainted with a native of the country, who applied to the parts affected a composition spread on coarse canvas, the properties of which were so wonderful that in a short time all the pain left him, the swelling disappeared, his sinews relieved, and he was able to resume his usual avocations. So effectual has been the remedy, that to this day he has enjoyed perfect health, without the slightest return of his former complaint. Knowing the great blessing such a remedy would be to those afflicted with this painful disease, he with great difficulty and expense obtained the secret of preparing the Plaster; and during the many years MR. MAC has applied these Plasters in New Zealand, Tasmania, New South Wales, and this city, their effect has been marvelous, giving to the most painful and long-standing cases sure and certain relief. The most incredulous will be convinced by referring to these persons: B. W. Owens, 405 Front street; F. B. Alderson, Traveling Agent for Dewey & Co., 414 Clay street; James Flynn, 519 Mission street; Michael Gorman, No. 6 Front street; Mrs. W. S Wright—late of Gilmore House—518 Folsom street, now agent at Virginia City; E. Shenley, corner Montgomery and Filbert streets; W. M. McLeod, Depository merican Tract Society, 557 Market street, and a host of others, who all bear testimony to the unparalleled healing powers of J. W. MAC'S (rightly termed Magic) Plasters, for the cure of Rheumatism, Gout, Weak Loins, Tender Feet and Neuralgia. J. W. MAC may be consulted at his office, rooms Nos. 34, 35 and 36, 128 Kearny street, San Francisco, between the hours of 9 to 12 A. M., 2 to 4 P. M. and 7 to 9 P. M.
18v20-3m

The Latest, Cheapest, and Most Durable.
CRANDALL'S
PATENT SPRING BED.
This invaluable Spiral Spring Bed combines all the good without any of the bad features of the common spring mattrass. It consists of a framework of springs resting on a bed of stronger springs, thus giving it nearly double the elasticity of any other bed. The springs are self-supporting, each pair being independent of the others, and consequently the tendency to sag or incline toward the middle is avoided. Unlike other spring beds, they require no upholstering, and, of course, afford no harbor for fleas or dust. The medical faculty have pronounced it the best Bed in use. It commends itself to those who have examined and used it. They invariably pronounce Crandall's Patent the best Spring Bed ever offered to the public.
These Beds are on exhibition and for sale at the Cabinet Warerooms of
JOHNSON & BEST,
No. 413 PINE STREET, RUSS BLOCK,
Between Montgomery and Kearny. Also at

Ayer's
Hair Vigor,
For restoring Gray Hair to its natural Vitality and Color.

A dressing which is at once agreeable, healthy, and effectual for preserving the hair. *Faded or gray hair is soon restored to its original color with the gloss and freshness of youth.* Thin hair is thickened, falling hair checked, and baldness often, though not always, cured by its use. Nothing can restore the hair where the follicles are destroyed, or the glands atrophied and decayed. But such as remain can be saved for usefulness by this application. Instead of fouling the hair with a pasty sediment, it will keep it clean and vigorous. Its occasional use will prevent the hair from turning gray or falling off, and consequently prevent baldness. Free from those deleterious substances which make some preparations dangerous and injurious to the hair, the Vigor can only benefit but not harm it. If wanted merely for a
HAIR DRESSING,
nothing else can be found so desirable. Containing neither oil nor dye, it does not soil white cambric, and yet lasts long on the hair, giving it a rich glossy lustre and a grateful perfume.
Prepared by Dr. J. C. Ayer & Co.,

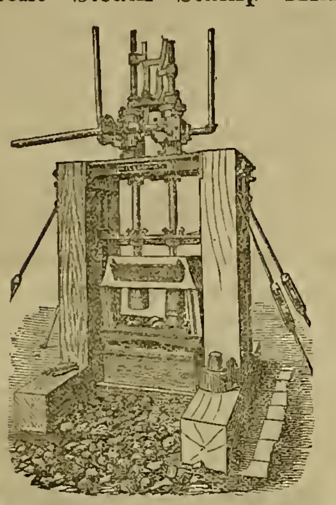
THE WILSON

Patent Steam Stamp Mill.



This extraordinary Mill, now so justly popular in the East, is now offered to the miners of the Pacific Coast. Having been in operation now for about eighteen months, the Company feel confident that the

WILSON STEAM STAMP MILL,

For Durability, Efficiency,

AND ECONOMY OF WORKING,

HAS NO EQUAL.

The Wilson Steam Stamp Mill is the only Steam Mill that has had the severe ordeal of practical working, and proved itself eminently successful. It is now in operation in several of the Eastern States and Territories, and gaining an envious popularity. The whole machine is so simple as to be readily understood by the most ordinary minds. In fact, its simplicity is its durability. The expense of crushing rock or cement with this Mill is less than one-half the expense of any other Stamp Mill, and less than one-half the cost. For further particulars inquire of

A. BICKNELE, Agent,
Nevada City, California,

Or of THE WILSON STEAM STAMP MILL CO., 326 Walnut street, Philadelphia, Pa.

Notice.—All persons are hereby warned not to manufacture or use any Steam Stamp Mills that are an infringement on the Wilson Patents, as they will be prosecuted to the utmost rigor of the law.

F. R. WILSON,
20v19-tf Supt. W. P. S. S. M. Co., Philadelphia.

VARNEY'S PATENT AMALGAMATOR

These Machines Stand Unrivaled.

For rapidly pulverizing and amalgamating ores, they have no equal. No effort has been, or will be, spared to have them constructed in the most perfect manner, and of the great number now in operation, not one has ever required repairs. The constant and increasing demand for them is sufficient evidence of their merits.

They are constructed so as to apply steam directly into the pulp, or with steam bottoms, as desired.

This Amalgamator Operates as Follows:

The pan being filled, the motion of the muller forces the pulp to the center, where it is drawn down through the aperture and between the grinding surfaces. Thence it is thrown to the periphery into the quicksilver. The curved plates again draw it to the center, where it passes down, and to the circumference as before. Thus it is constantly passing in a regular flow between the grinding surfaces and into the quicksilver, until the ore is reduced to an impalpable powder, and the metal amalgamated.

Setlers made on the same principle excel all others.—They bring the pulp so constantly and perfectly in contact with quicksilver, that the particles are rapidly and completely absorbed.

Mill men are invited to examine these pans and setlers for themselves, at the office, 229 Fremont street,
1v1 San Francisco.

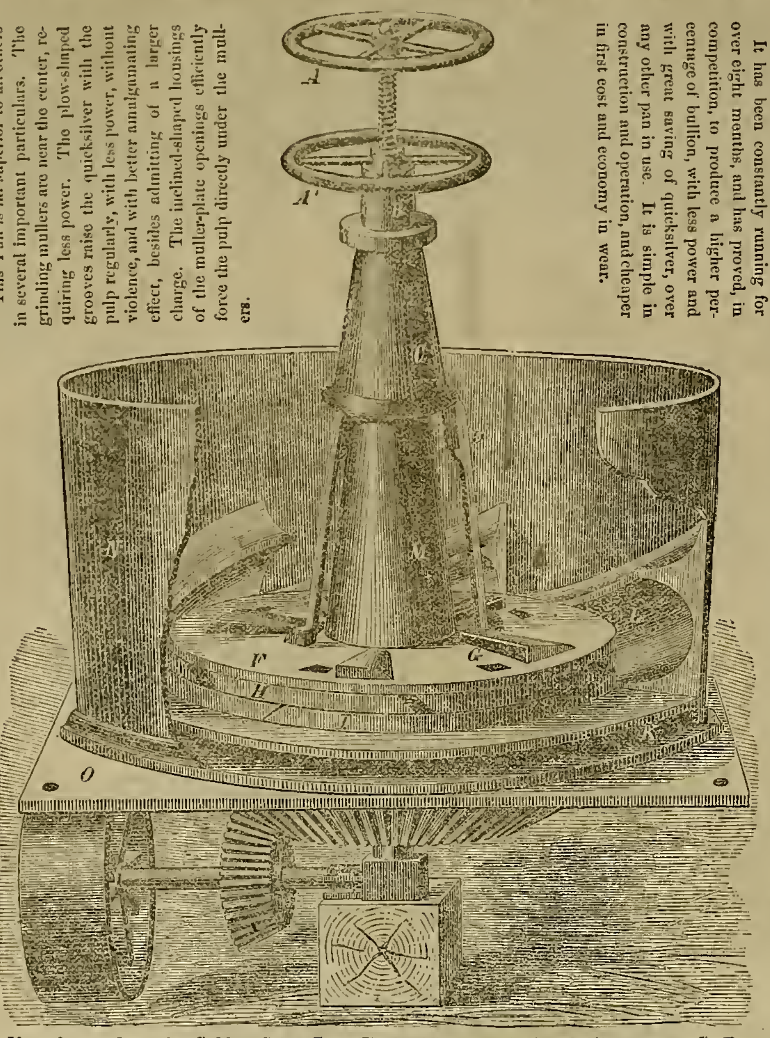
TO MILLMEN.

FOR SALE CHEAP.—A 10-stamp mill complete; engine about 35 horse-power; cylinder 12-inch bore and 30 inch stroke; boiler 16 feet long and 48 inch diameter; weight of stamps complete, 650 pounds. The whole is as good as new; has only been running four months. Will sell either engine or battery separate, and deliver it on the railroad, at Auburn if required. For particulars apply to W NAGEL, 702 Bush street, San Francisco, or to MOUNTAIN CO., Forest Hill, Placer county. 16v20-3m

STEVENSON'S PATENT MOULD BOARD AMALGAMATING PAN.

This Pan is far superior to all others in several important particulars. The grinding mullers are near the center, requiring less power. The plow-shaped grooves raise the quicksilver with the pulp regularly, with less power, without violence, and with better amalgamating effect, besides admitting of a larger charge. The inclined-shaped housings of the muller-plate openings efficiently force the pulp directly under the mullers.

It has been constantly running for over eight months, and has proved, in competition, to produce a higher percentage of bullion, with less power and with great saving of quicksilver, over any other pan in use. It is simple in construction and operation, and cheaper in first cost and economy in wear.



Manufactured at the Golden State Iron Works (Co-operative). 19 First street, S. F.,

Where it can be examined and further particulars be learned; or persons may apply to the inventor and patentee, Mr. C. C. STEVENSON, at the Douglas Mine, Gold Hill, State of Nevada, where the Pans have long been in constant operation. 15v20-1mr,1amtf

Patents on the Pacific Coast.—To those of our friends who desire to keep posted upon inventions upon the Pacific coast we say, subscribe for the Scientific Press, published by Dewey & Co., San Francisco, Cal., at $4 per year. The opening of the railway across the continent has given to all patents a much higher value in that portion of our country known as the Pacific slope, and all interested will find the paper above alluded to a valuable reference.—*Mechanic and Inventor Detroit, Michigan.*

Illustrate your Inventions

In the Scientific Press,

An illustrated journal of Mining, Farming, Mechanic Arts and Industries on the Pacific Coast. It costs no more for a superior engraving by our experienced artists than is usually charged for a less perfect picture. If you wish to introduce a new invention properly before the public, the first steps in so doing are important ones. A full description and correct representation in the Press will go further and prove more quickly effective than any other means.

The fact that an illustration is admitted into our columns, guarantees the invention important consideration in the minds of thousands of the most intelligent readers—at home and abroad—who would not notice it so favorably or so thoroughly, if at all, when presented through an unreliable medium or indifferent source.

The model of an invention sent to us is sufficient for making a good engraving, Sometimes a photographic view is sufficient; but it is always best accompanied with drawings or a copy of the patent. A first-class illustration has proved to be one of the best and cheapest means of obtaining purchasers for a good machine or a valuable patent.

Cuts ordered for illustration are the property of the inventor who pays for them, and can generally be used for circulars, pamphlets, books, or other newspapers. The engravings to be seen in each issue of the Scientific Press are a fair sample of the work of the artists who can always be found in our office.

Important to Assayers.

Crucibles.

The Patent Plumbago Crucible Co.

Manufacturers of all kinds of

Melting Pots, Portable Furnaces,
CRUCIBLES, and other fire-standing Goods,
Battersea Works, London.

THE MORGAN PATENT CRUCIBLES have uniform quality, never crack, withstand the greatest heat without danger; heats more rapidly than any other; change of temperature has no effect on them; stand on the average forty to fifty pourings.

CERTIFICATES:

United States Branch Mint, San Francisco, Cal., March 12, 1869—Messrs A. S. Hallidie & Co, Agents Morgan Crucible:—I have carefully tested the Morgan Patent Plumbago Crucibles purchased from you for the U. S. B. Mint, and cheerfully certify to their superiority and economy over all other Crucibles used by and under me. They are fully what you represent them, and I shall continue to use them in preference to any other. J. M. ECKFELDT,
Melter and Refiner, U. S. B. Mint.

Eagle Brass Foundry, 206 Fremont street, San Francisco 12th March, 1869—Messrs. A. S. Hallidie & Co., 519 Front street—Gentlemen:—We have used and tested tho Morgan Patent Plumbago Crucible, for which you are agents, and pronounce them superior to and cheaper than any Crucible used by us heretofore. GREENBERG & MOORE.

Messrs. A. S. Hallidie & Co.:—We have thoroughly and severely tested in every way the Morgan Patent Plumbago Crucible obtained by us from you, and find them superior to any we have yet tried, although we have used every pot obtainable in this market, we have none equal to the above, and concede your claims for them. We think they will average 45 pourings of brass.
GALLAGHER, WEED & CO.,
California Brass Works, 125 Front street, San Francisco.

Assay Office of H. Harris, Silver City, Nevada, April 24, 1869—Messrs. A. S Hallidie & Co.—Gents.:—I received from you three Crucibles of tho Morgan make, which I have used since their arrival, and tested by constant use. Since 1847, when in the New Orleans Mint, I have always preferred tho Crucible of Dixon's make over Adus, Gautier, and Taunton, Mass. Yours I find to be not alone of more finished make, but to stand double or treble the work of Dixon's Crucibles. The No. 12—the smallest sent—has stood so far 32 meltings, and is as good and sound as when received. Your Crucibles do not scale off like others; and as they are forty-per cent. cheaper, I do not see why they should not be preferred by all assayers on account of durability and cheapness. Yours respectfully, H. HARRIS.

On hand and for sale by the Agents,

WIESTER & CO.,

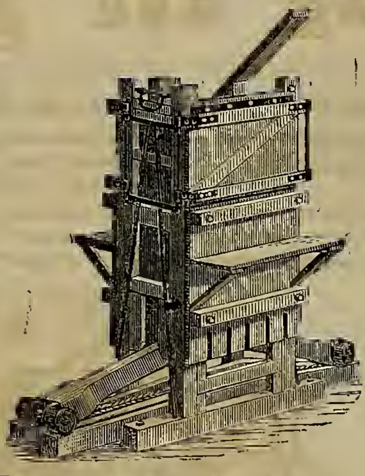
PATENT BROKERS,

No. 314 Bush Street, San Francisco.

PATENTS BOUGHT AND SOLD ON COMMISSION.

For the benefit of those who live at a distance from the city, we give below a brief description of a few of the valuable Patents which we have in our office. It may be well to state here that no Patent is received by us for negotiation until it is first endorsed by reliable experts, to whom each is subjected for acceptance or rejection. We treat all patents alike, recommending only where true merit is found in the invention.

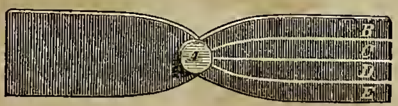
EAGLE HAY PRESS.



PATENTED JANUARY 10, 1865, AND JULY 24, 1866.

Here is an invention that we take pleasure in recommending. There is probably no farming implement more perfect in its line than this Press. It has advantages over any and all other Presses now in use. It costs only $300 and weighs only 1,500 pounds, which is $100 lower in price and 1,500 pounds less in weight than any other good Press on the Pacific coast Three men and a pair of horses with this Press can bale from ten to fifteen tons per day, each bale weighing from 250 to 350 pounds. The power is applied by means of two levers acting on the principle of the toggle-joint, and the pressure acquired as they approach a vertical position can scarcely be estimated. On account of the great power obtained in this Press, it is well adapted to baleing hides, rags, wool, cotton, etc. They can be built at any blacksmith and wagon shop. They cost to manufacture $150 less than any other firs-class Press in the United States. A large number have already been sold, and all are giving good satisfaction. The Right to California, Oregon and Nevada will be sold in States or counties. We keep on hand well built sample Presses to furnish to parties buying territory. Any information in regard to the Press or territory can be obtained by addressing WIESTER & CO., 314 Bush street, San Francisco.

RYAN'S NEW METHOD OF MAKING WHEELS.



To make indestructible iron wheels with little labor and at small cost, is the object of this invention. The hub and spokes are all made out of a single piece of iron. It is first forged down at the ends to the thickness required for the spokes, leaving a hub in the center. The ends are then split into four or more strips each, as shown in the cut above. A represents the hub; B, C, D, E, when spread to their proper position, form the spokes to one-half the wheel. When the other half is split and spread in a similar manner, the spokes are then rounded and shoulders formed on them ready to receive the tire or rim. It is claimed that the great amount of labor and expense heretofore required in making wrought-iron wheels is obviated by this novel mode of construction. There probably never has been a wheel made that is so durable as the Ryan Wheel, and yet the method of construction is so simple that it can be made by any ordinary mechanic in a common blacksmith shop. All territory west of the Rocky Mountains for sale in States or counties. Thomas Ryan, of Scott's Bar, California, is the inventor. Sample wheels, and tho iron from which they are made, can be seen at our office, 314 Bush street, San Francisco

NEW LIGHT ON A NEW PRINCIPLE.

Gas for everybody in the city and in the country. Equal to coal gas at one-half tho cost. The gas is generated and burned in a new style Vapor Lamp. No wick, no chimney, no explosion; and no man who is out of business and has a few dollars should fail to purchase a County or State Right and commence making money. Parties owning territory get the Lamps at manufacturers' prices. Call and examine the Light or write for particulars.

WIESTER & CO.,
314 Bush Street, San Francisco.

J. S. PHILLIPS, M. E.,

Examiner of Mines, Consulting Engineer, Mineral Assayer,

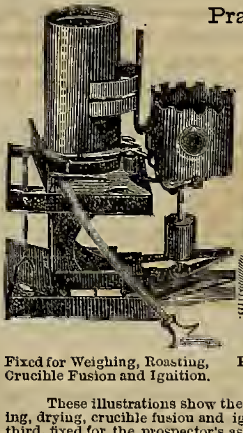
ANALYST, ETC., ETC.

No. 423 Washington Street, San Francisco.

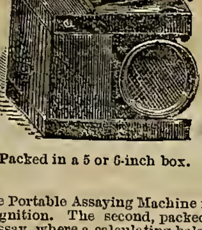
Inventor of the Explorers', Miners', Millers' and Smelters' Friend, the Prospectors' "WEE PET" Assaying Machine, etc., which obtained a Gold Medal at the San Francisco Mechanics' Institute Fair of 1869.

Practical Instruction in Assaying.

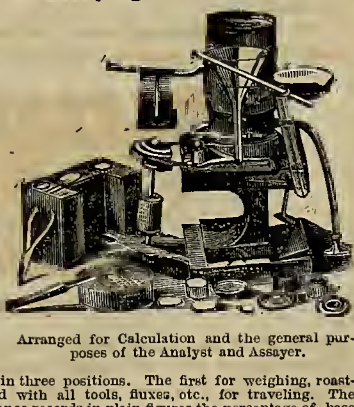
Patented Sept. 7, 1869.



Fixed for Weighing, Roasting, Crucible Fusion and Ignition.



Packed in a 5 or 6-inch box.



Arranged for Calculation and the general purposes of the Analyst and Assayer.

These illustrations show the Portable Assaying Machine in three positions. The first for weighing, roasting, drying, crucible fusion and ignition. The second, packed with all tools, fluxes, etc., for traveling. The third, fixed for the prospector's assay, where a calculating balance records in plain figures the percentage of base metals, thousandth's fine, or $ per ton of bullion, and the dollars (or oz.) per ton of gold and silver assays; for the analyst to fuse ten or twenty grains, alone, on charcoal, or with an alkaline carbonate, etc., for open and close test tubing, or to dry, sublime, evaporate, boil, distill, filter, etc.; showing also the tools and flux-box.

This Machine is intended for prospectors, who can, after a few hours of instruction, assay their own rock, at a cost of ten cents per assay, which can be performed so much more easily in the field that it must supersede all other methods. Price, $100, which includes instruction, tools, calculating balance, weights, fluxes, etc.

SCIENTIFIC PRESS.

AN ILLUSTRATED JOURNAL OF SCIENTIFIC AND INDUSTRIAL PROGRESS,

Mining, Farming and Mechanic Arts.

BY DEWEY & CO.,
Patent Solicitors.

San Francisco, Saturday, June 18, 1870.

VOLUME XX.
Number 25.

Bracket Pattern Dead-Stroke Hammers.

Metal workers and others often need a light hammer which will give a quick light blow, without requiring so much power as is furnished by the heavier hammers. For striking up tin, copper or cold iron, such a hammer is particularly useful, and an efficient device of the kind would probably find a wide use.

The necessity of a light class of hammers, permitting an enlarged space between the hammer-frame and the anvil-bed, led a Philadelphia firm to make the "Bracket Pattern" hammer, of which a correct idea can be formed from the annexed cut. This appears to be a very neat and effective device, which can be worked very rapidly, and which can be easily placed where most convenient. There are four sizes made, in which the weight of the ram is 5, 15, 25 and 50 pounds, and which cost at the shop in Philadelphia $125, $250, $300 and $450 respectively.

As before stated such a device admits of quite an extensive application. For shovel makers, the two larger patterns are highly recommended, for cold hammering their moulds for the purpose of stiffening or finishing them. To saw-makers, who need a light blow for reducing the "fash" left by toothing, the manufacturers offer their 5-pound hammer as a most efficient and expeditious tool; and many others will find them most useful and ecomomical. The hammers are sent out with treadle attachment and everything finished to start them, after the hammer is bolted to its frame and the anvil-bed to the block on which it is to stand.

There is a large field on our coast for just such a device as this, and the many artisans who do considerable work in the way of light forging, planishing, etc., would do well to examine the hammer, which has met the approval of manufacturers to a large extent. Further information on the matter can be obtained by applying to Philip S. Justice, 14 N. Fifth street, Philadelphia, or 42 Cliff street, New York.

◆

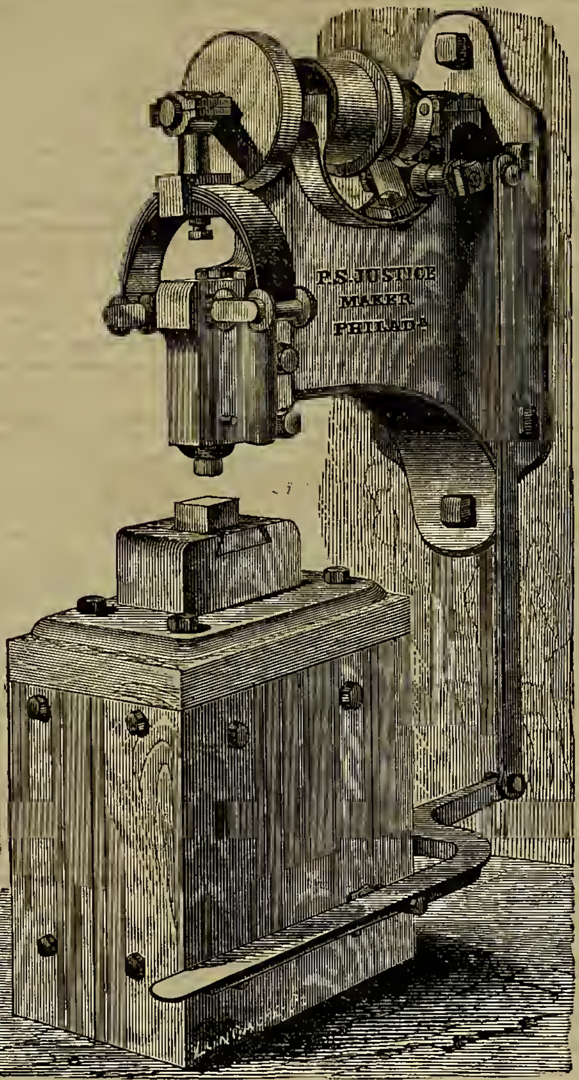
Charles Dickens is dead. The announcement has carried sorrow wherever the English language is spoken. There is no person now living who has won so large a share of the affections of the people everywhere, no writer or statesman who has exerted so universal an influence, as this master of wit and pathos. His wonderful power of description, his superabundant humor, have made him beloved throughout England and America, and made his death a public loss.

◆

A Very Fair Yield.—Mr. H. C. Jones, of Sutter county, up to the 10th inst., had harvested and threshed 205 acres of barley, with an average yield of 27½ bushels to the acre.

◆

Steamship Line to Australia.—The *Call* has been informed that a new line of steamships between this port and Australia will be inaugurated about the first of July.

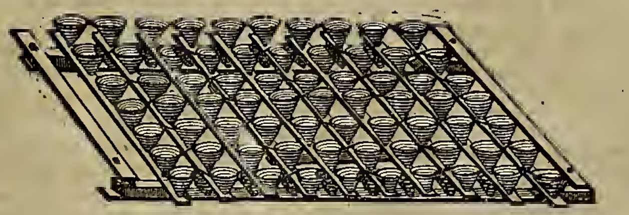


SHAW & JUSTICE'S BRACKET PATTERN DEAD-STROKE HAMMER.

Crandall's Patent Spring Bed.

Sancho Panza blessed the man who invented sleep. He might have gone a step farther and blessed the men who render that invention of easy and comfortable application.

His second blessing would include a large number of persons. The cook, the doctor, all in fact whose efforts conduce to the mental and physical health of mankind, would deserve a chronic or periodic share, and an especially large portion would, of right, be reserved to the inventor of spring beds. According to all accounts and testimonials, the inventor of the device here illustrated would have made Sancho a supremely happy man, and have evoked his heartiest benedictions. By this construction it is sought to provide a bed as easy as that "of roses" of the poets, without allowing the presence of thorns of any kind. The bed consists simply of a framework of springs, resting on one of stronger springs, and thus greatly increasing the elasticity commonly obtained. These springs are self-supporting, each pair being independent of the others, and thus the tendency to sag or incline towards the middle is avoided. They are light, durable and elastic, and present no harborage for bugs or other vermin. The mattress is laid on the springs and can be removed and aired at will. The whole is exceedingly simple.



CRANDALL'S PATENT SPRING BED.

The names of many prominent citizens of this city are given as willing witnesses of the superior quality of this device, which is now coming extensively into use, as we are informed. It is certainly worth the trouble for housekeepers to examine the bed. It is manufactured by Messrs. Cooley & Green, corner of Front and M streets, Sacramento, who have as agents S. B. Snedakar, 413 Pine street, S. F.; W. H. Sarles, San José; Mr. Nichols, Stockton; Irwin & Garnett, Oakland; Mr. Murphy, Vallejo; and E. A Tompkins, Grass Valley.

◆

Tin Ore from San Bernardino.—A second lot of tin ore, some 500 pounds, has been received in this city from the recently discovered tin mines near San Bernardino county. The San Diego *News* is informed that it is from a ledge 80 feet wide! The ore comes to this city for the purpose of enlisting capital for the developing of the mine. The idea of the existence of workable tin-bearing lodes in various portions of the southern part of the State, seems to be gaining ground, and we trust that capital will soon be found to fully settle the question one way or the other. The question of title, we believe, has had much hitherto to do with the investment of capital in this direction, and, indeed, we are not even yet informed whether that difficulty has been entirely removed.

We have heard of another lot of "tin ore" which has been forwarded to this city, and which contains "silver enough to pay all expenses." We do not believe that it is *tin* ore at all.

◆

Earthquakes.—According to advices from Japan, that country has experienced, in the vicinity of Yokohama, a severe earthquake. The volcano of Asayama, after a rest of a very great length of time, has had an eruption, causing the peasantry to quit the fields in terror. In Mexico, the earthquake at Oaxaco, previously mentioned, is reported as most severe, destroying almost the whole of the southern part of the city, and injuring the buildings throughout the place. One hundred and three persons are reported killed.

◆

Another Wreck.—The North Pacific Transportation Company's steamer Active, Capt. C. E. Lyons, left here for Victoria on the 4th inst. with 117 passengers. On the 5th, it struck a rock off Cape Mendocino. The vessel commenced to leak so badly that it was necessary to beach her. The passengers were safely transferred to the land. The passengers, according to a resolution, compliment the Captain on his conduct after the accident.

◆

The work of harvesting is now well under way, and the grain crop is likely to turn out much better than was expected four or five weeks since. At all events, the increased price, now and prospective, will bring the net returns for the present crop fully up to that of last year.

Communications.

Mines on the Western Slope of White Pine Mountain.

[Written for the Scientific Press.]

While at Hamilton I stopped at Dr. Spaulding's hotel. This is a fine establishment, and seems to be the general headquarters for those who come to stop for a short time. The Doctor is an old pioneer who came to the land of gold in '49, and who concluded finally to settle down in White Pine. He has built a good hotel here, the best in the district, and I can assure anyone coming hither that they can find a very comfortable house by stopping at Spaulding's.

I have had the opportunity of going over the western slope of White Pine Mountain, where I visited a large number of mines. The Trench is looking very well indeed. The Superintendent showed me a small specimen of native silver, the first I have seen here. Ore is being extracted which is valued at $700 per ton. According to the *Daily News*, an ably conducted sheet, $75,000 have been recently offered, and refused, for the mine. I think it is, without doubt, the biggest thing here at present.

The Vanderbilt and Uncle Sam mines, taken up by Mr. Hanson in 1865, at Mohawk Cañon, are looking finely, and show some fine rock. In this cañon, on the left hand side, is the first ledge discovered in the district, in 1865, by Messrs. Morrill & Leathers, and called the Mohawk. It can be traced for a distance of 800 feet, and contains base ore which must be smelted. Among the locations at this place may be mentioned the Crown Point, Honest Indian, Wyoming and others, all looking splendidly. I am informed that the rock from the Honest Indian has run from $95 to $238 per ton, and is being worked by Mr. James Devlin, one of the owners. It is situated about 300 feet above the Mohawk ledge, running parallel with it, is about two feet wide on the surface, and is without doubt a very promising mine.

Passing on to the old Morrill & Leather's Cañon, about three miles due west, I visited the ledge named after the early prospectors, Messrs. Morrill & Leathers. This ledge is one of the longest, and as wide as any, which I have seen. The old company has commenced operations and is taking out fine ore. The ledge was *re-located* by the Montabella S. M. Co., and called the Perley lode, after the well-known lawer, Judge Perley. A suit is to be commenced concerning the matter, to determine whether the old company has done the necessary amount of work to hold their claim from 1865 to the present year.

Not far from this is the Queen City, located by Mr. A. J. Brown and others. Mr. B. is the Deputy Recorder here, a fine gentleman and an old miner in the section. He has another promising claim on the Zavala ledge. This is two feet wide, is being worked by a small force of men, and shows very fine ore, some of the very best, indeed, which I have yet seen. The Montabella Company made some good locations here in May, 1869, which are looking admirably well. The Niagara (located in 1865, as the Mammoth) ledge has also been re-located by this company.

I also visited the Murray ledge, located last year. This appears to be a very valuable mine, and the company has on the dump some very fine ore, which assays from $100 to $150 per ton. The rock contains rich galena, and is partly decomposed. This, like the other ledges here, runs east and west, and there is a general dip into the hill of about 45°. The hillsides are rough and precipitous. In the cañon are some fine springs and a plenty of wood, which would render easy the running of smelting furnaces. There are none as yet, I understand, on this (the west) side of White Pine Mountain, but I am convinced that a well-managed company here would do a very profitable business, as there is plenty of ore. There is no difficulty in getting charcoal, and many men are now employed in making this useful article The Monte Cristo mill has been running steadily for some time, but is going to make way for one of Mr. Stetefeldt's furnaces, which will be a great gain for the district.

The Cariboo ledge is located near the base of the mountain, and is the property of the White Pine S. M. Co. It is large and well defined and well charged with ore of a high grade. About forty tons of $100-ore have been taken from the mine and are now on the dump. The vein pitches into the mountain at an angle of about 40°, and shows a degree of uniformity and permanency rarely seen in the mines of the district. It is from four to seven feet wide, and steadily increasing in size as explorations are extended into the mountain. About $2,000 worth of work has been done on this claim. The ledge is favorably situated for profitable working, being near the Monte Cristo mill. There is also an abundance of wood and water in the immediate vicinity. Estimating the ore to be worth $100 per ton in the ledge, which is putting it low, it can, with the advantages of the locality, be mined and milled for $20 per ton—leaving a clear profit of $80 on every ton reduced. The Porcupine ledge is situated near the celebrated Trench mine, and bids fair to develop into one of the best mines in the district. The present developments are not as extensive as those on the Cariboo, but it presents the most favorable indications of opening quite as well, if not better. The ore is of a free order, and is easily treated by simple mill process. Assays run from $100 to $1,200, and it is safe to estimate that the entire body of ore in the vein will yield $100 to the ton in silver, and from $10 to $15 in gold. Work on an extensive scale will be inaugurated on this ledge before long. These statements, with regard to the Cariboo and Porcupine ledges, were given me by the very gentlemanly reporter of the Elko *Independent*.

I might write concerning other operations, but have given you enough for this time. The formation on this slope is limestone and slate, and is *said* to be older than that of Treasure Hill. The idea prevails here among miners that there is a very large mother-vein running through the mountain, and that these veins mentioned are merely feeders. While I have no proofs of the correctness of this idea, I, of course, am unable to disprove it, and so mention it merely for what it may be worth. So much I believe, that there is good ore here which will pay well those who will work diligently and in good faith. The camp is now looking up and business is improving.

Hamilton, Nevada. W. H. M.

Smelting in Cerro Gordo, Inyo County.

[Written for the Scientific Press.]

Editors Press :—In accordance with my promise, I will now proceed to describe the *modus operandi* of the base metal workings in this camp.

The galenas are first charged into a reverbatory furnace, and there smelted with about one-third of their *bulk* of rich silver quartz, forming what is commonly called here *slag*, but which in reality is a rich lead *matt*, which is run out on the ground and allowed to cool and is then broken up, and piled away to be used again in the blast furnace.

The blast furnace is a circular one, about 8 feet in the clear in height and 20 inches in diameter in the clear at the bottom, with an inside batter of 95° to the top of the eight feet, built of fire brick, 14 inches long, moulded in the form to make the inside diameter above stated, and 12 feet in circumference on the outside. It is hooded over all at the top with common red brick, having a square hole in the side of the hood, 18x24 inches to admit the charges. The fire brick are made of Kaolin (of which we have an abundance here), mixed with one-third of pure white quartz sand, merely dried in the sun.

Furnaces built in this way run from 12 to 15 days. The charges consist of

5 parts matt or slag;
1 " raw galena ore, broken to egg size;
1 " raw silver rock, broken rather smaller;
2 " galena and iron oxides;
1 " carbonate of lime,
with about 2 bushels of charcoal.

The charges are regulated by decreasing or increasing as necessity requires. The molten lead carries the fine metals the ore contains with it to the bottom, and runs into a receptacle in front of, and on a level with, the bottom of the furnace. The slag also runs into this receptacle and overflows, and runs off, where it cools, and is wheeled away and dumped into a pile, as of no farther use. When the receptacle in front of the furnace is nearly full of molten metal, it is tapped at the bottom, and the lead allowed to run into a hole or pot, made of fire clay sunk into the earthen floor of the building. Here it is permitted to stand a while, to collect what is here called "fierros" (being in reality a very rich matt, containing silver, copper, iron and antimony), which rises to the top of the pot, and forms a very hard scum, varying in thickness from half an inch to three inches. When this scum is removed, the lead is dipped with an iron ladle and poured into iron moulds, forming pigs 83 pounds in weight. This sized furnace ages 80 such pigs in 24 hours when the furnaces are running well.

In my next I will give you the results of the operations in other parts of the Owens River country. Crowquill.

Cerro Gordo, June 6th, 1870.

Quartz Mining in Victoria.

In looking over the history of mining in Victoria, one finds it a matter of great interest to compare the statistics given in the earlier and the later years. For instance, we find that in 1862, 16,703 men extracted and worked 567,208 tons of quartz, which yielded an average of 10 dwt., 22 grs., or $10.88 per ton. There were 461 steam engines of 8,055-horse power in the aggregate employed in hoisting and crushing quartz, and 82 machines, driven by other than steam power, employed in crushing. In 1868, 14,079 men extracted and worked 886.228 tons, which yielded an average of 10 dwt. 15.37 grs., or $10.16 per ton. There were 602 steam engines of 11,045-horse power, 66 machines driven otherwise than by steam, and 5,997 stamps.

According to these statistics, it appears that the number of quartz miners decreased in this time. But it also appears that the smaller number of laborers extracted a larger amount of quartz, notwithstanding the fact that much of the ore must have been taken from lower depths, where, of course, the labor and the expense must have been much greater. Again, it may be noticed that in 1863 the average earning of quartz miners for the year was $615.94; for 1868, it was $828.31. The average yield remained about the same, being a little less in 1868; but probably the improved methods would have raised the average in the earlier days.

Such facts as these are certainly anything but adverse to the prospects of mining as a business. Well may Mr. Smyth remark in his work, to which reference has been made so often in the Press: "The records of the mining department show that the average yield of gold from quartz crushed at Ballarat is very low. This, instead of having a prejudicial effect on mining operations generally, has been singularly beneficial. It has induced economy in working, brought into use and to completeness many excellent appliances for saving fine gold, and has served to train managers and workmen better and more effectually than any mining-school teaching could do. If not a direct benefit to Ballarat, it has had a remarkable effect on quartz mining generally; leading to the use of simple, easily-worked appliances, and proving that care and skill in the use of these are often sufficient to compensate for any inherent defects in them." M.

Appleton's Journal.—The number of journals devoted to literature and art is a strong indication of the increase of taste among our reading public. We have previously spoken of several of these, and it is a pleasure to me to-day to recommend another, not a new one, however, which deservedly enjoys a large degree of popularity. *Appleton's Journal* has now nearly reached its fourth volume. Published weekly, attractively illustrated, with frequently a large extra cartoon, and filled with choice sketches, essays and stories, it is a most pleasant companion for the family circle, and a choice addition to any table. We have long read it with pleasure, and the reception of the last number leads us to give it a hearty recommendation to our friends on the coast.

The curled leaf appears to be seriously troubling the peach trees in some portions of the State.

Farming in Santa Clara.

Throughout the Santa Clara valley I find many settlers that have "seen the elephant" of early mining excitement, and have endured the hardships of life in the mountains. Wherever these individuals are settled with their families, prosperity, if not riches, is commanded by that liberal spirit of enterprise which is a characteristic of old Californians. And by the intelligent toil and habitual energy so sure of success in such industrial occupations as do not depend on "luck and chance" as mining must, or at least does depend, they are sure to win the rewards of honest labor. Any man that will earnestly and intelligently apply himself to a business that he can manage, as the occupation of a piece of land of the right size, can succeed in making more than a mere living, and in developing some good.

Among others, my attention has been attracted to the comfortable, well-cultivated, beautiful, orderly and houselike place of Mr. W. A. Z. Edwards, who lives near San José. With but forty acres of ground—enough, he says, quite as much as he can do justice to—he has a dairy of seven very excellent cows, from which he raises as many calves yearly, and makes a large quantity of superior butter. He last year sold butter to the value of $634.25, besides using freely from it for his family, as well as liberally of fresh milk. The buttermilk and skim-milk, fed to the pigs and chickens, was also a source of considerable profit. He has a fine imported Alderney bull (the only pure-blooded one that I have seen in California), six years old, that he is breeding his cows to. He aims to produce a superior butter-making dairy stock.

The reputation of the Alderney stock as as butter-makers, stands ahead of all others. Mr. E. says that the Ayershires will yield more milk, but that the Alderney will make the most butter. With good feed, five quarts of milk will yield a pound of butter. The Alderney breed of stock is small, but well formed, docile, active, and with capacious stomachs. They can easily travel about, are hearty eaters, and, when feed is plenty, enjoy the quiet and rest so necessary for good milk stock. Mr. E. has several fine crossed yearlings and calves that he prizes very highly. He is ardently in earnest, and practically asserting his interest in this enterprise. I took some statistical notes from him, but having lost the same, can give only such a superficial idea as forcibly impressed my mind. His pastures, his fields, his orchard, his garden, everything, shows a provident management and an economical but liberal care. With his forty acres, he has a better home, makes more money, and has more and better stock than many farmers with 400 acres.

This State is open to a thousand worthy enterprises; enterprises that should be regarded as something more than speculation; enterprises that rise superior to land-grabbing and insatiable thirst for more; legitimate, earnest, honest enterprises that will reward the worthy, and that invite the intelligence, the labor, the capital, the energies of the people. There are many places, many worthy enterprises in this valley, as beautifully and as frugally and intelligently managed; many that I might, and some that I intend to notice. But whether studied into and expatiated upon, or simply glanced at or passed over, they are none the less valuable in themselves, while they are the foundation of all meritorious success, the promise of prosperity and the assurance of advancement in material progress. S. H. Herring.

Cave Remains prove Nothing.—"'Granting that the cave-men co-existed with cave-carnivores in Europe, what hinders us from supposing that these stone-folk were emigrants from Asia, who leaving behind them a high civilization sank in the scale by a corrupt life, like the Boers of South Africa? The quality and quantity of food has a marked effect upon the *physique;* a low forehead may signify a life of misery and want rather than a primitive type of human kind. Is the age of stone in Western Europe necessarily the stage of universal infancy? Are not the Red Men our contemporaries? We find troglodytes and stone-ages all along the track of human history; we have yet to discover the first stone-age of the *race*."—*Prof. Orton.*

Mechanical Progress.

Another Arrangement for Burning Petroleum.

We condense the following from the Philadelphia *Engineer:* "On May 26th we were present at the trial of Whipple & Dickerson's new process. It may be briefly described as follows: Steam from the boiler passes into the fire-box, where it is forced through a small iron super-heater, thence it passes through a pipe into a cylindrical generator four feet high and two and a half in diameter, which contains six hundred copper tubes of half an inch in diameter. The steam passes into these tubes, and the oil is contained in the spaces around them. This intense heat converts the oil into a gaseous vapor with great rapidity. As fast as generated, the vapor passes into a receiver, which encloses the generator like a water jacket; then rising through a layer of sponges in the dome of the machine to steady the flow, the gas passes through a pipe to the fire-box, and escapes through a frame of burners, like ordinary gas, and there burns with a flame and heat far greater than any produced with coal. In addition to this, just at the point in the dome where the vapor passes into the pipe which conveys it to the fire-box, a jet of this super-heated steam is turned into the same pipe, and at high temperature and pressure mingles with the carbon vapor, and both pass into the fire-box, where they are both consumed.

At the foundry in which this process is in operation, there has been a saving of nearly one-half in coal, with an increased efficiency."

The Martin Process in America.—The London *Engineering* gives a letter from a New Jersey steel-maker at whose establishment have been made several important improvements over the original, as regards the manner of working. The product resulting is unsurpassed. We quote detached paragraphs: "We have succeeded best in the manufacture of soft steel, and are now using it largely for boiler plate, for which it is admirably adapted. One of the tests given by the locomotive builders is to punch a rivet hole at the usual distance from the edge of a sheet, and then drive taper drifts through the hole till it breaks. It is usually found that the diameter of the hole is doubled before the metal is burst apart, and the same occurs if the plate is first heated red hot, and cooled off in water. * * When the percentage of carbon does not exceed 0.25 per cent., the steel possesses the singular property of being very decidedly toughened by plunging in water at a red heat. After this treatment it is much stiffer, yet so far from being brittle as to resist the effect of bending better than before. * * From the experience which we have had we are satisfied that this is to be *the* process for the manufacture of superior grades of soft steel, and though it may not quite compete with the Bessemer process in cheapness, yet the steel so far surpasses that in quality as to enable it to be used for purposes whose requirements the Bessemer steel is unable to meet."

New Rolling Mill.—At the late meeting of the Iron and Steel Institute,—says *Engineering* of May 13th,—"a new form of rolling mill by Mr. Brown was exhibited by a model, this mill consisting of a double pair of rolls driven in opposite directions, and in which the working grooves of each pair are placed opposite to blanks or large recesses in the other pair of rolls. This mill has the drawback as compared with the Dowlais mill, which it most resembles, that it requires additional length of rolls to allow for the blank spaces or grooves. Compared with the mill "three rolls high" it offers decided advantages, and compared with the reversing rolling mill it presents the advantage of having a continuous movement in all its parts."

New Process for Fixing Dyes.—Mr. Kipping, of Manchester, Eng., dissolves gelatin in water, and adds bichromate of potassa in the proportion of 3 ozs. to 20 ozs. of gelatin. This is done in a dark room. To this the coloring matter is added. The goods, after being submitted thereto, are exposed to the action of light, whereby the pigment becomes insoluble in water, and the color therefore fast.

Slight Loss in Transmitted Compressed-Air Power.

"The value of the recent experiment at Galena consists in its demonstration that the loss of power is so slight as to be of no special consequence compared with the important pecuniary gain which would result from the substitution of air power for steam power. In that experiment it was found necessary to transmit compressed air from the surface, where it was obtained by air pumps, worked by a steam engine of 10-horse power, through pipes down a shaft of 1,300 feet in depth, in order there to work a pump for expelling the foul air to the surface. It was found that the air, thus compressed, formed at that distance a motive power equal to a 9-horse power engine on the spot; that the loss of one-tenth in power arose almost wholly from the friction of the air pumps, and in only a very slight degree from the transmission of the air through the pipes."

The *Bureau* remarks: "While steam would cool and lose its power in any attempt to transmit it through pipes a few score feet, compressed air could be transmitted for thousands of feet. Hence, if the machinery for compressing the air be erected in one block so protected as to be fire-proof, the pipes will carry the power to the machinery in any number of blocks, which being thereby freed from the introduction of heat into their premises, may be surrounded by any quantity of combustible matters without increasing liability to fire. Where block after block is filled with saw and planing mills, wagon and blind factories, and even foundries, machine shops, and grist mills, the reduction of insurance would amount to a saving of hundreds of thousands annually."

Testing the Duty of Steam Engines. At a late meeting of the Polytechnic Association of the American Institute, Dr. Van der Weyde, after explaining various methods for doing this, named as preferable the one which consists in recording the units of heat carried off by the exhaust steam. By simply providing a condensing engine for any specific time with a definite quantity of water as a condensing agent, and noting, by means of a thermometer, the degrees of heat communicated to it by the condensation of the steam, the quantity of heat carried off by the exhaust may be found by a simple calculation. The units of heat thus carried off in the exhaust are of course so much abstracted from the force employed to drive the piston, and the less this quantity of heat, other conditions being equal, the more efficient the engine for a given expenditure of fuel.

An English Stone-Breaker.—We find the following feeble attempt at an evasion of Blake's patent, described in the usual English style, in one of our exchanges: "In constructing the apparatus, the fixed jaws are placed vertically, as in some of the machines now used, but the crushing block or movable jaw is made with two faces or working surfaces, and this block is made to oscillate on a center placed either above or below a central point midway between the two fixed jaws. As an obvious modification, instead of a single oscillating block, two movable blocks, connected together by links or other equivalent devices, but mounted on distinct shafts, may be used. It is preferred to actuate the crushing block or blocks by means of an eccentric mounted on a horizontal shaft, which passes through an opening made in the block or between the two blocks."

Turning Alloys.—The hardness of zinc, copper and tin alloys causes them to blunt the edge of the turning tool when in the lathe. It is said that if the point of the tool be moistened with petroleum, the work will proceed as readily as with red-hot metal. Steel tempered to a light yellow has been turned with the greatest facility by using a mixture of two parts of petroleum and one of oil of turpentine.

Improvement in Relay Magnets.—The *Telegrapher* describes one which consists in arranging the connections of a relay so that the main circuit is divided, one-half passing through each helix, and uniting again on the opposite side, instead of having the conducting wire of the two spools continuous, as in the usual manner. It will be seen that the total resistance will be reduced one-fourth

Scientific Progress.

An Island Electrified.

A curious discovery has been recently made at the French Company's telegraph station on the little island of St. Pierre Miquelon. It was found that the delicate Thomson receiving instruments used by the French Co. were so seriously affected by earth-currents that the signals were often unreliable. The inconvenience was removed by laying an insulated wire from the station to the sea, and attaching to it a large plate of metal immersed therein; this plate becoming practically the earth for that station, and less liable to change, as to its electrical condition, than the rocky soil of the island. Upon placing the Thomson instrument in the course of this 3-mile insulated wire, it was found that the messages of another telegraph line—the Anglo-American—the station of which is also on the island, could be read. This latter company receives messages from Newfoundland, and sends them to Sydney, using a powerful battery and the Morse signals. These messages were in several instances automaticaly recorded by the sensitive Thompson apparatus of the French company when made to form part of the insulated connection aforesaid. We quote the explanation from *Nature:*

"It must be clearly understood that the American lines come nowhere into contact, or even into the neighborhood of the French line. The two stations are several hundred yards apart, and yet messages sent at one station are distinctly read at the other; the only connection between the two being through the earth; and it is clear that they would be so received and read at fifty stations in the neighborhood at once. The explanation is obvious enough; the potential of the ground in the neighborhood of the stations is alternately raised and lowered by the powerful battery used to send the American signals. The potential of the sea at the other end of the short insulated line remains almost, if not wholly, unaffected by these, and thus the island acts like a sort of great Leyden jar, continually charged by the American battery, and discharged in part through the short insulated French line. Each time the American operator depresses his sending key he not only sends a current through his lines, but electrifies the whole island, and this electrification is detected and recorded by the rival company's instruments.

It is clear that unless special precautions are taken at isolated stations, an inquisitive neighbor owning a short insulated wire might steal all messages without making any connection between his instrument and the cable or land line. Luckily, the remedy is simple enough. All owners of important isolated stations should use earth plates at sea, and at sea only. This plan was devised by Mr Varley years ago, to eliminate what we may term natural earth currents, and now it should be used to avoid the production of artificial earth-currents which may be improperly made use of."

Dawson vs. Darwin.

Prof. Dawson, in the *Canadian Naturalist,* objects to the Darwinian theory, for divers reasons, and holds to the "modern ideas of derivation." He considers the hypothesis advocated by Prof. Cope in his memoir on the "Origin of Genera," read before the Academy of Natural Sciences in Philadelphia, "the most promising of these modern hypotheses." He says:

"The facts point to the operation of two causes—first, the possible *retardation* or *acceleration* of development, and secondly, the action of outward circumstances on the organism capable of this retardation or acceleration. We here substitute for the tendency to vary of Owen's theory, the ascertained fact of reproductive retardation or acceleration, and for the struggle for existence, the action of changed physical conditions, and for the question as to the change of one species into another, the change of the same species from one genus into another. * * According to this view, a species once created may have in itself a capacity for passing through several generic forms, constituting a cycle which ever tends to return into itself, or to advance and recede by steps more or less abrupt under the law of retardation and acceleration, combined with the influence of external circumstances. Yet the dimensions of the orbit of each species must be limited, its duration in time must also be limited, and its capacity to pass into a really new species must still be a point subject to doubt, but open to anatomical investigation and inference."

The paper of Prof. Dawson is reviewed by A. Hyatt in the *American Naturalist* for June. We quote briefly: "According to the theory of natural selection only favored races can prolong their existence by perpetually inheriting the advantages of their ancestors, and certainly the degradational characteristics as displayed in all the terminal species of the ammonoids cannot be explained in this way. Here also we have the limitation of the cycle of changes or variations, of which a species or form may be supposed to be capable, at least partially accounted for; and as Professor Dawson and others have pointed out, the theory of natural selection makes no provision for such restrictions. * * The law certainly explains much which has been hitherto inexplicable. It gives us, perhaps, the means of asserting that the plasticity of organs have certain limits; that variations can arise from natural selection, or physical changes, only when these act in given directions and for a given time, after the expiration of which, whether in the individual or the group, if sudden death do not intervene, all changes must be degradational in character. Physical causes, and the struggle for existence, can no longer improve the vitiated organization when it has passed this period. Its death is decreed as certainly as its line of developmental changes must have been before it was born."

Surface Geology of the Basin of the Great Lakes.

Prof. J. S. Newberry has an article on this subject in the *American Naturalist* for June. We have space only for the following conclusions:

1st.—That in a period probably synchronous with the glacial epoch of Europe,—at least corresponding to it in the sequence of events,—the northern half of the continent of North America had a climate comparable with that of Greenland; so cold, that wherever there was a copious precipitation of moisture from oceanic evaporation, that moisture was congealed and formed glaciers which flowed by various routes towards the sea.

2d.—That the courses of these ancient glaciers corresponded in a general way with the present channels of drainage. The direction of the glacial furrows proves that one of these ice rivers flowed from Lake Huron, along a channel now filled with drift, and known to be at least one hundred and fifty feet deep, into Lake Erie, which was then not a lake, but an excavated valley into which the streams of Northern Ohio flowed, one hundred feet or more below the present lake level. Following the line of the major axis of Lake Erie to near its eastern extremity, here turning northeast, this glacier passed through some channel on the Canadian side, now filled up, into Lake Ontario, and thence found its way to the sea either by the St. Lawrence or by the Mohawk and Hudson. Another glacier occupied the bed of Lake Michigan, having an outlet southward through a channel—now concealed by the heavy beds of drift which occupy the surface about the south end of the lake—passing near Bloomington, Illinois, and by some route yet unknown reaching the trough of the Mississippi, which was then much deeper than at present.

3d.—At this period the continent must have been several hundred feet higher than now, as is proved by the deeply excavated channels of the Columbia, Golden Gate, Mississippi, Hudson, etc., which could never have been cut by the streams that now occupy them, unless flowing with greater rapidity and at a lower level than they now do.

Atmospheric Germs of Disease.—*Scientific Opinion* considers that Prof. Tyndall's recently promulgated doctrine in reference to floating organic particles is "incapable of proof";—is a hypothesis, and nothing more;—and that Berkley and other able fungologists are distinctly opposed to it.

Mining Summary.

The following information is gleaned mostly from journals published in the interior, in close proximity to the mines mentioned.

California.

ALPINE COUNTY.

Items.—*Miner*, June 4th: Soft ore and an increase of water in the east drift of M. C. Tunnel No. 3 indicate an approach to the east wall....Yesterday six tons of low-grade ore from the Schenectady was hauled to the Monitor C. M. Co's mill.... Since the survey of Mountain No. 1 made it apparent that running in granite don't pay, work has been commenced in the upper works....Mr. Graff will not order the mill for the Schenectady until, by the completion of the lower tunnel, and the average of the low-grade ores, it can be determined whether a five-ton or a fifty-ton mill is required.

AMADOR COUNTY.

Coney.—*Ledger*, 11th: The work of freeing this mine of water progresses rapidly, and so far, the timbers have been found in good condition. The owners are tearing away the old mill with the design to erect a large one as soon as they sink 200 feet deeper.

CALAVERAS COUNTY.

Hoisting Works.—*Chronicle*, 11th: James Gleason, of the Inoline Tunnel mine, is erecting hoisting works. As the ditch is in close proximity to the mine, the machinery will be run by water power. A hurdy-gurdy wheel is being constructed.

EL DORADO COUNTY.

El Dorado.—Cor. of Placerville *Democrat*, 11th: The Pocahantas Co. have 30 men employed underground, and realize $200 per day. The Havilah Co., on the Cosumnes, is paying handsomely.

MARIPOSA COUNTY.

Coulterville.—*Gazette*, 10th: G. Douglass has succeeded in getting the water out of the Melvina mine. Everything now is in first rate working order, sufficient rock being taken out to keep thirty-five stamps of the old French mill constantly pounding....The owners of the Marble Spring mine have a train of thirty-five mules hauling rock to the Eclipse mill on the Merced river. W. C. Priest, superintendent of the Eclipse, is still working on the tunnel commenced eight months ago to strike the vein 100 feet above the old levels.

NEVADA COUNTY.

A Blast.—*Transcript*, 8th: Yesterday a blast of 3,700 pounds of powder was discharged in the claim of Maltman & Marselus, at Manzanita hill. A tunnel has been run into the bank 150 feet, and a cross tunnel of 50 feet, in which the powder was placed. The blast did splendid execution.

North Bloomfield.—This company is getting ready for opening the ditch from the big dam at Cañon creek. About four miles yet to be completed, and men are going from points on the ridge to work.

Omega.—Same of 12th: We learn that the miners are doing well, and anticipate that the present season will be the best they have had for some years. More men are employed than ever before, and more gold has been taken out.

Good Prospects.—The San José Co., east of the ridge above the Young America, have got into the gravel lead, and find favorable prospects. One pan of dirt yielded a dollar and a half.

Manhattan.—The owners of this ledge, on Gold Flat, have purchased the machinery used on the Wagoner, which they are having put up on the Manhattan.

Prospecting.—*Gazette*, 10th: Judge Freeman is prospecting half a mile above Washington with a gang of Chinamen. He is developing a second level of gravel on the bench of the river.

Columbia Hill.—Gentlemen inform us that mining operations are almost entirely suspended for the season on account of a lack of water.

Rich Strike.—Same of 11th: The owners of the Grizzly Hill mine, near Eureka, opening a new ledge 50 yards above their old one, have taken out several tons of the richest looking rock ever found on that ridge. The ledge is two feet in width.

Wisconsin.—Grass Valley *Union*, 7th: This mine is worked on the coöperative plan. During the last four weeks the miners have been sinking on the ledge and doing other work not immediately profitable. Yet the mill has given $5,000.

Eureka.—Same of 8th: This mine had a run of 12 days, and cleaned up the amalgamating apparatus without touching the battery, and not reckoning a cent from sulphurets. The showing is three bricks, weighing 160 pounds, and valued at $31,672.29.

Allison Ranch.—A run of three weeks gives $10,000, with a profit of between $4,000 and $5,000. Sinking on the ledge and other developments have been going on during the time, and the mill was not constantly employed. The company are contemplating the erection of a new mill.

Empire.—This mine is just fairly commencing work under the new management. We saw some fine rock in front of the batteries yesterday; on the day before, exceedingly rich rock had been put through.

The North Star mine is doing well.

The Coe is crushing.

Tribute.—Same of 11th: Some miners are working in the upper drifts and abandoned stopes of the Empire, and pay to the company a percentage of the proceeds. A few days ago very rich rock was taken out and crushed, and the proceeds amounted to $6,000 for 19 tons.

PLACER COUNTY.

St. Patrick.—*Herald*, June 11th: Mr. Eaton has sold the mine to Cronise, Capt. Lee, Melville, Atwood & Co., for $46,000, and the new owners have taken possession. Mr. Townsend has been placed in charge, and machinery is being shipped from below. We learn that the company intend to continue the shaft to a depth of 125 feet, and then run levels to test the mine.

At Work Again.—Mr. Eaton, late owner of the St. Patrick, has commenced work on a small parallel vein. This vein passes through the old Doeig mines, which yielded such quantities of gold years ago.

Forest Hill.—In the old Lamb claims, in piping off the face of the bank they worked into a soft quartz deposit from 50 to 75 feet wide. This mass is distinct from the other formations flanking it, contains free gold, and presents the appearance of containing a heavy percentage of silver.

Further up the divide, half way between Forest Hill and Michigan Bluff, Charles Fett has struck a quartz ledge three feet wide, which, by partial assay, shows $45 to the ton. At Michigan Bluff, Van Emen's claims are paying well. The water is beginning to fail, and the mine will soon have to be laid by for the season. A new discovery has been made, or rather rich gravel has been struck, in the Weske claims, between Michigan Bluff and Deadwood. The deposit was found week before last, and six men in six days took out 237½ ounces. Last Chance is reported lively.

Ophir.—Cor. of same: Our mills are crowded with custom work. The shaft on the Minersks, near North Ravine, is down 50 feet. The May Day claim is having 14 tons of rock tested at the Empire mill. Work on the Green mine goes on with good results. Good Friday has yielded so far $30,000, and you will hear more of it. Empire has a shaft down 62 feet. The first five tons of rock crushed paid 14½ ozs.; the next 85 paid $60 per ton. Clunan & Co., of Grass Valley, are sinking a shaft on a ledge near Green's. They had ten tons crushed which paid $15 per ton. From the Hunter prospect shaft a crushing gave $12. From the Cornucopia 250 tons of rock has worked $16 per ton. Simon & Marian's claim on Humbug Flat has yielded $35. Price & Co's extension had 21 tons crushed last week which paid $30 per ton. Shinghe & Emery are crushing rock that will yield $16 per ton. Mr. Battis had 22 tons crushed from the Shipley ledge which yielded $22.50 per ton. Staples & Co. are having 100 tons from the Hathaway mine crushed at the St. Lawrence mill which pays more than ever before. This ledge is three feet wide.

Michigan Bluff.—Cor. of *Stars and Stripes*, 9th: Mr. Weiske owns a claim, two miles above this town, which he has worked for years with such poor success that he has run in debt over six thousand dollars....Last fall he struck rich pay in the back part of his tunnel, which runs into the divide nearly a mile. He has paid all his debts and four weeks ago started for Germany. Since he left, his claim has shelled out $7,000 in cash, over expenses, and a little over $4,000 last week—114 ounces being taken out in one pan. This is, no doubt, the lead which commences at the Dardanelles, passes through Forest Hill, Bath, and extends to Damascus..... The Franklin, adjoining, struck the same lead.....Mr. Bowen has struck rich pay in his claim....Prospects in Upper Placer are cheering.

SAN BERNARDINO COUNTY.

Rising Sun.—*Guardian*, June 4th: This is the name of the rich ledge discovered some weeks ago by a squaw southeast of town. It is owned by Messrs. Schafer, Kreuter and others, and is three feet wide, and down eighteen.

More Gold.—Los Angeles *News*, 11th: Some fine specimens of gold and silver bearing rock from the lately discovered leads in San Bernardino arrived yesterday. We learn that capitalists have succeeded in purchasing several leads.

SAN DIEGO COUNTY.

More Quartz.—*Union*, 9th: Edward Valliere, of New San Diego, sends us a remarkably rich piece of float rock from a gulch in the Cuyamaca range. He says there are tons of this quality of loose rock. The earth in the gulch prospects from three to ten cents to the pan.

SIERRA COUNTY.

Large Nugget.—*Messenger*, 11th: A China Co. brought to town, on Sunday, a piece of gold found on the south fork, valued at $440.

SISKIYOU COUNTY.

Items.—Yreka *Union*, June 10th: On Salmon, Black Bear and Klamath are paying well. The owners of the Jackass will erect a mill. Other ledges promise well.. On Scott bar the ledge of Ryan & Williams is still rich....Pfenninger & Co. have a valuable claim on Virginia bar.... The claim at the lower end of Humbug promises to pay better than ever. They got out of the boxes, after finishing ground-sluicing, 85 ounces.

A Yreka telegram, dated June 14th, says that J. Mallory has discovered a very rich gold-bearing quartz lode one mile north of that place. He has been at it for seven years with a divining rod as guide. The rock paid in a mortar $17 per pound. Visitors are excluded from the mine.

TRINITY COUNTY.

Junction City.—Cor. of *Journal*, 11th: The bringing in the water of Brown's Creek ditch to the bars and high benches from its mouth to the mouth of North fork, would be a good speculation for San Francisco capitalists. The whole cost of the first 30 miles would not be more than $60,000; and that would cover enough ground, known to be rich, to last ten years.

YUBA COUNTY.

Pennsylvania Mine.—*Appeal*, 10th: An assessment has been levied for working purposes of $1 per share, and E. W. Roberts employed as Superintendent. Work will be done on incline No. 2, and rock taken out for crushing from the lower level.

Arizona.

Items.—Prescott *Miner*, May 28th: Last clean-up at Big Bug was good....The tailings from the Vernon ore which C. Y. Shelton packed on his back to the creek, making therefrom $30 per day in a rocker, were last week worked in an arastra, and yielded $230 to the ton....Work at the Sterling mill and mine has been suspended ....Some placer mining is being done. Among dust recently brought from Lynx creek, was an ounce piece....The Vulture City keeps up its lick.

Colorado.

Items.—Central City *Herald*, 8th: Capt. Dean's claim on the Seaton is yielding richer ore than ever....Mr. Freeman and Dr. McCaskill have gone to work on the Rising Sun. The shaft is 280 feet deep. An engine will be put up to-day....Gen. Wingfell has bought No. six east of the Seaton. The shaft, 62 feet, has been re-timbered. He is to put up a residence, a boarding house, and a new whim and shaft-house....Alex. Cameron has built a 1,800-feet flume on North Clear creek, and will extend it 400 feet farther. Ten men are sluicing, and in ten days there will be 25.

Chicago Creek.—Cor. of *Register*, 8th: Stewart & Airey, in Cascade gulch, will get in a quartz mill as soon as possible. Dickerson & Dora will arastra surface ore, without desulphurization. The Plymouth Rock is showing a strong vein of ruby, brittle silver, and sulphurets. The Cynosure is improving rapidly. The Silver Bluff is producing pay.

Items.—Georgetown *Miner*, June 2d: The pyrites in the Terrible has been found by assay to return 422 ounces silver per ton. Twenty tons of first-class ore will soon be shipped to England....Crevice on the Gen. O'Neil is four feet wide; eight inches of mineral in the bottom of the shaft. Average returns by milling will be $150 per ton....Summit county placers will yield largely this season....Crevice in the Creole is six feet wide, and the 8-inch vein at the bottom of the shaft assays $500 to $1,000.

Bullion.—The Brown Co. shipped on Tuesday 325 pounds troy, currency value, $5,000. The Baker Co. shipped to Philadelphia, yesterday, a silver brick weighing 1.004.5 ounces. The coin value was $841.57.

Idaho.

Snake River Mines.—Cor. of *Statesman*, 4th: The river is on the decline, and in six weeks all will be well again in these diggings. High water prospects are more encouraging than ever. A party of prospectors just returned, report prospects of from five to twenty-five dollars per day, up and down the river.

Items.—*Avalanche:* Golden Chariot shute is full of ore and hundreds of tons heaped outside. Rich ore coming out from fourth level. Large amounts of best sacked....A whim has been erected on the Empire....Ida Elmore has a good start.. Coduroy yields quartz rich both in gold and silver....Poorman has plenty of ore, and will put on more men....Home Resort is down 40 feet, and looks well.... Peck pleased with prospect on Potosi..... Good reports from the placers. Shuster & Co. work 22 men in Blue gulch. Six weeks' water yet. Sullivan Bros. have a monster hydraulic in Jacobs' gulch. Clean-up in Peck & Porter paid an ounce per day per hand. Garlick & Co. on Long gulch find nuggets worth 50 cents to $1.

Montana.

Boulder.—*New North-West*, June 4th: About 250 men in the gulch and tributaries. The ground is paying from $4 to $100 per day to the hand. The richest claims are those of Halford, Hunter Jack, and Olinger, on Basin, and Reed & Co's Black Dirt Diggings, on Cataract Creek. The latter pays from $75 to $100 per day to the hand. Stuart & Co., on Alta Gulch, struck bed-rock last week, and began on $25 per day to the hand.

Silver Bow.—All lovely now; all the ditches running full, the ground saturated, and snow deep on the mountains. Chime & Oakwood cleaned up $1,000 from a four days' run; other companies have done well. Bernard's ditch sold $3,000 worth, and the Pioneer and Rocker ditch $3,200 worth of water last week.

Rocker.—There are 100 men at work. Wages $5 per day, $6 per night, in gold dust, at $16 per ounce. Owens & Co. cleaned up $700 for a four days' run, four hands.

Bilk Gulch.—There are only a dozen claims, all of which are owned by Col. Morse, Gil Simmons, and Capt. Plaisted. They are running three strings of sluices with 12 men. Last summer they had only 40 minutes' water per day, and at that the yield was $30 per day to the man.

Highland.—*Independent*, 4th: The Only Chance and Nevin's Companies are running their arastras constantly. The Highland Co's mill is idle.

Yreka.—Doolsy, Kennedy & Co. are doing well. Dugan & Dooley are working a breast of 60 feet, and taking out large quantities of gold. Stone & McKibbet cleaned up $650 one day last week. Grant, McGorem & Highland are making an ounce a day on an average. McGu & Co., in Day's gulch, are making from $10 to $12 per day to the hand.

Top O'Deep.—Mell McGee & Co., Ferguson & Co., Prince & Co., McPhael & Co., Flanagan & Co., Curley & Co., O'Conner & Masterson, McDermott & Co., Terrill & Davis, are making from $7 to $18 a day to the hand.

Pilgrim Bar.—Blair & Thornton, ground sluicing, made a clean up, after a three and one-half days' run, and took out $1,825. The previous clean ups during thirteen and one-half days, swell the amount to $6,126.60. Holcomb, Beery & Co. cleaned up $2,500. Several other companies did well.

Meadow Creek.—Cor. of *Capital Times*, 3d: Eight or ten companies in Washington and Blue Sag are paying $6 to $8 per day to the hand. Miners generally have ground enough to last for years;—which is as it should be, as they have spent years in prospecting and preparing it.

Items.—Same of 6th: Snap & Peel, at Adobe Town, cleaned up on Saturday $300. Mr. Olson is taking out $75 to the set of timbers. About sixty are at work about Adobe Town, and there is not an idle man. Armitage Brothers, below Nevada, made a clean up Saturday of $350. after four days' run with three men..J. M. Trivett came in from Silver Star, Saturday, with 190 ounces of retort, the result of a seventy-two hours' run with 10 stamps, on the Iron Rod.

Cedar Creek.—R. O. Bailey reports: There are 3,000 to 4,000 men in the camp —at least 1,500 more than ought to be. When Mr. Bailey left there were 15 sluices running, but the recent storm has undoubtedly stopped one-half of these. They were paying from wages to a little more. Wages are $6 per day.

Nevada.

COPE DISTRICT.

Argenta.—Elko *Chronicle*, June 9th: John Dixon reports everything prosperous. Drew & Co's mill had to stop two days for want of quicksilver, but now is pounding away on the contract of 1,600 tons from the Argenta and Excelsior.

Treasure.—The following amounts passed through Wells, Fargo & Co's office at this place from the 4th to the 8th June: From Mountain City, $3,000; Idaho, $22,000; White Pine, $21,000; total, $46,000.

Bruno District—J. Norton, from a tributary of the Owyhee, exhibits gold-bearing quartz from a new discovery. The ledge is four feet wide. Working tests satisfactory. Water power convenient.

HUMBOLDT.

Rebel Creek.—*Register*, June 11th: W. M. Tanner and others have been surface mining on Rebel creek, fifty miles north of this place, for four months. The mines have yielded regularly from four to six dollars per day to the man.

Railroad District.—*Independent*, 8th: Work is progressing on the Wisconsin Chief, Mountain Boy, West Humboldt, Union, Bunker Hill, Constitution, Bullion, Mayflower, Bald Eagle, San Francisco and Crystal Peak.

REESE RIVER.

Mineral Hill.—Elko *Chronicle*, June 12th: The Co. have had ore worked at Austin and Reno, with an average result of $503 per ton from the Live Yankee, Mary Ann, Star of the West, Give Out, Giant, Great Republic, Silver Queen, Vallejo, Grey Eagle and several others. One lot from the Star of the West worked $950.37 per ton; one lot of 20 tons from the Austin worked $630 per ton. Hundreds of tons of float have been gathered on the sides of the hill, which worked from $150 to $300 per ton. Curtis & Huber, old mill and mine men are putting up a mill to cost $60,000, with no other guarantee than the mines themselves offer.

Cive Hill is two miles south of Mineral Hill. Prospects are "first-class."

WASHOE.

Crown Point.—Gold Hill *News*, 11th: Sixty tons low-grade ore daily from the upper levels. The annual report to May 1st says: There were 2,227 tons of ore worked at the Rhode Island mill, yielding $15.52, and 3,615 worked at the Petaluma, yielding $13.14—showing an average yield for the year of $14.12, while the cost of working the ore was $11.12 per ton. Bullion produced, $76,167.

Imperial-Empire.—The winze from the 1,100-foot level was down 86 feet this morning, and shows improvement in the ore.

Hope.—The body of ore at the lowest level continues yielding well. Both mills are steadily running, the daily yield of the mine being from 30 to 35 tons of $20 ore.

Yellow Jacket.—Daily yield, 270 tons, from the 900 and 800-foot levels. The ore body being worked north and upward toward the 800-foot level, is the best ever found in the mine. It is being breasted out over 50 feet in width.

Ophir.—Both southwest drifts at the lower level of the new works are progressing well, with good indications and a decrease of water. The shaft of the pump broke day before yesterday. It will take a week to get the water out in consequence.

Hale & Norcross.—The repairs to the shaft being concluded, and work resumed at the lowest levels, the daily yield is again increased to 200 tons.

Virginia Consolidated.—A heavy increase of water was tapped Tuesday in the drift west from the 500-foot station of the new shaft, which drove the workmen out, and has kept the bailing tanks in full operation ever since.

Occidental.—The old upper portion of the mine is yielding at the same regular rate. No increase of water. Work on the new mill progressing.

Gould & Curry.—Daily yield, 80 tons.

Belcher.—The ore yield shows a falling off, owing to the surface stopes above the 152-foot level and the ore seam above 262-foot level giving signs of exhaustion. Some fair ore near north boundary line.

Sacramento & Meredith.—The new mill is running splendidly, with a plentiful supply of water and plenty of good ore.

Chollar-Potosi.—Daily yield, 175 tons. The Belvidere section still continues its extra yield. Receipts for May, $146,983.79.

Sierra Nevada.—Both mill and mine running steadily.

Caledonia.—*Enterprise*, 12th: About 40 tons per day of fair ore extracted. The Piute and Sapphire mills are supplied with ore from this mine.

Sutro Tunnel.—The tunnel is in 1,225 feet, and is now in regular casing, with a strong indication of soon striking a ledge.

The Comstock "Giving Out."—Bonsfield & Co., assayers, in this city, day before yesterday received 3,300 pounds—nearly a ton and three-quarters—of crude bullion for melting and assay, and yesterday morning by 9 o'clock all was in forty bars, worth between $90,000 and $100,000.

WHITE PINE.

Review.—*News:* The apparent inactivity in mining is due, in part, to pending negotiations. These include a number of heavy sales, and also several important consolidations, and the uniting of mills and mines under one management. The shipment for last week amounted to $31,586.03, of which, $18,143.25 went West, and $13,442.78 East. In addition to this, 547 bars of base bullion was shipped, weighing 45,932 pounds, and 48,833 pounds of base ore.

Items.—Anchor Consolidated has struck a rich and extensive body of ore....South Aurora is taking exceedingly rich ore from the Autumn Pit and the drift. The Stanford mill turns out over $3,000 per day from the ore of this mine, and the supply seems inexhaustible......Domingo still yields largely of good ore....Aurora Consolidated is shipping ore steadily....Treasure Hill Co. extracts 15 to 20 tons of high-grade Summit ore daily....Virginia looks better than ever....Manhattan has been started again....Borealis will start soon. The sale of the Eberhardt and other mines has been consummated....A German prospector in the Pinto Range sent a quartz specimen for assay which went over $1,500 in gold....The Alsop Smelting Works have fired up again....In ten days the Alsop turned out 36 tons of bullion.... Dayton mill has been leased to Chas. Coover.

Outside Districts.—Ely is showing improvement. Pattersou is reviving, and a well known millman contemplates putting up a mill there. Silver Park is shipping bullion steadily. The smelting works at Robinson have not yet started up, but the mines are yielding base ore of high grade. Piermont and Shoshone are expecting mills during the summer, and Cooper will probably have one or two before fall. Fraser & Wormer have been at work for two months on Duck creek, in Galena district. Assay of the ore warranting the move, they sunk a shaft, took out 20 tons, and are preparing to make a test by smelting. Pinto prospects are encouraging. The shaft of the Maryland mine is down 90 feet, through ore that will average $200 to $1,200 to the ton. There is 120 tons of ore sacked, and 65 tons have been shipped, which have averaged $200 per ton in San Francisco. The Champion looks well, and is being worked. The Pinto Co's mines are all being worked.

Edward Stahl is working a promising mine called the Sunburst. He has struck a ledge of ores at a depth of eight feet which shows a vein one foot wide.

Yellow Pine.—Los Angeles *News*, June 10th: Mr. Chas. S. Scott brought to this city a piece of silver ore from his mine in Yellow Pine district, weighing 846 pounds, which surpasses in richness anything we have ever seen.

New Mexico.

Items—*Press and Telegraph*, May 28th: **Spanish Bar.**—Bloomfield & Co. have a very regular pay streak, and average $6 per day to the man, at a cost of $3.50....McBride & Co., in the hed of the Moreno, have a long string of claims, and have done an immense amount of work with as yet light returns. Prospects are improving. ....Currey & Co., Grouse Gulch, have had good dividends, but now are idle for want of water.....Bowers & Co. have been getting $8 to the hand per day.....Tom Pollock has eight men, and averages $6 per day to each, at an expense of $2.50. He sinks a shaft 20 feet to bed-rock, drifts, puts in 100 pounds or so of blasting powder, places a long fuse to it, throws back the loose dirt, and touches a match to the fuse. The hard cement is then ready for ground sluicing, from grass-roots to bed-rock.... Michigan Co., besides cleaning their pit of the wash from the bursted reservoir, cleaned up a pound of gold last week.... Carpenter & Lowthian have made repairs and are ready for work again....Sutton's hill diggings pay $5 per hand per day.

Eagle Mine.—The *New Mexican* gives these figures: From January 21st to April 31st, 1870, 1,000 tons of ore were worked, producing 3,788 ounces of gold bullion, valued in currency at $74,760.

The New Mines.—Letter to the *New Mexican*, dated May 7th, says every claim has so far proved even richer than anticipated. Hundreds of feet of ledges that rise in places 50 feet above the surface, contain ores that assay thousands of dollars to the ton. Mills are on the way. Wood is scarce—must be brought 25 miles. Water abundant at 15 feet depth. Few claims have changed hands; 25 feet in the Valley claim sold for $1,000 to Col. Sam. Jones.

The San Diego *Union* gives part of a letter from D. O. McCarthy, dated Ralston, May 22d: "I have been examining the mines in company with Messrs. Arnold, Hutchinson, Governor Safford and Colonel Dunn, and I tell you that the truth has not been half told. Great fissure leads, *standing up in the air*, one to two hundred feet high, and three to five hundred feet in width, every pound rich with silver ore that will pay fifty to five thousand dollars a ton."

The *Bulletin's* own correspondent writes from Ralston, May 22d, that 1,257 claims had been recorded. The three monster veins, Harpending, Brown, and Arnold, crop out for miles, in places 50 feet above the surface, and varying in width from a few feet to hundreds. There is more good looking ore in sight than has ever been worked in the mills in and about Virginia and Gold Hill. But little work has been done, except to hold the claims. Men with no money had better stay away for the present, as there is no demand for labor.

A Mesilla letter to the Santa Fé *Post* of June 4th says parties are hauling lumber 75 miles for building purposes. Ore from several of the lodes has assayed in San Francisco and Philadelphia from $500 to $8,000 per ton.

Oregon.

A Lump.—Dalles *Mountaineer*, June 7th: A nugget of gold valued at $3,966.64 was taken out of a claim at Gimletville, Baker county, owned by Dr. S. A. Caldwell, on the 30th of May.

Quartz.—Jacksonville *Sentinel*, 11th: We are informed that a rich gold-bearing ledge has been discovered on the divide at the head of Indian creek, Josephine county.

New Incorporations.

The following have filed certificates with the County Clerk, San Francisco:

Masonic Hall Association.—June 9. Capital stock, $250,000; 25,000 shares. Trustees: A. G. Abell, E. W. Bourne, L. Cohn, I. C. Davis, E. V. Hathway, A. Hollub, J. Laidley, W. M. Rundell and C. L. Wiggin.

Deep Spring Valley M. Co.—Mono county, June 10. Capital Stock, $100,000; 2,000 shares. Trustees: T. Tennant, J. McCloskey, C. Bogan, O. P. Fitzgerald, P. O'Sullivan and D. Conkling.

Panaca M. Co.—Nevada, June 11. Capital stock, $1,000,000; 10,000 shares. Trustees: G. Kustel, A. B. Judson, S. A. Raymond, W. Gardner and E. Tripp.

General Lee S. M. Co.—White Pine, June 15. Capital stock, $2,000,000; 20,000 shares. Trustees: W. B. Cook, J. L. Haskell, H. C. Patridge, A. Rushmore and Charles F. Schulze.

Meetings, Elections, Etc.

Hearst M. Co.—June 6. Trustees: D. D. Colton, J. O. Earl, M. S. Latham, S. M. Wilson, C. E. Johnson.

Bromide Flat M Co.—June 7. Directors: W. E. Barron, A. E. Head, D. D. Colton, A. Hayward and G. Hearst.

Sacramento & Meredith M. Co.—June 15. Trustees: J. B. Haggin (President), J. M. Livingston (Vice-President), Lloyd Tevis, R. E. Brewster, W. W. Blow. Secretary, W. Doolan; Superintendent, T. F. Smith.

A **gold nugget**, valued at $3,966, is reported as recently taken out of a claim at Gimletville, Baker county, Oregon.

San Francisco Mining Stock Market.

The sales of several prominent stocks mentioned in our last report continued to nearly as large an extent as the previous week, Original Hidden Treasure showing a material recession, while Savage, Yellow Jacket, Chollar-Potosi and several others have been well maintained. The amount of business transacted may be considered quite large for this season of the year, but during the past week did not extend over so large a range of stocks as heretofore. However, it seems to us that the severe depression which has ruled for some time past is about to take a change, and that the recent activity of a number of stocks apparently points to such a conclusion.

The aggregate sales in the San Francisco Stock and Exchange Board, during the month of May, for a series of years, have been as follows:

May, 1865	$5,665,549	May, 1868	$10,162,390
May, 1866	3,052,102	May, 1869	8,961,913
May, 1867	7,651,855	May, 1870	4,558,765

The total sales during the first five months of the past six years have been as follows:

In 1865	$19,793,934	In 1868	$52,435,060
In 1866	18,868,761	In 1869	35 965,647
In 1867	24,249,002	In 1870	24,191,731

Chollar-Potosi—continues to be well maintained, under ordinary sales. During the week closing June 10th, 1,230 tons of ore were extracted, showing an average assay value of $52 33 per ton; previous week, 1,200 tons were extracted. In the Belvidere section, both in raising and sinking the shaft from the surface, which connects with the "raise" from the 18th floor, they passed through good ore. The Blue Wing and New Tunnel sections of the mine are yielding their usual supply of ore, the same being of a somewhat better quality. The drift running west from the top of "raise" in the New Shaft is 47½ feet long, passing through porphyry and clay. The drift running north is 102 feet long, requiring 70 feet to connect with the 6th floor of Potosi shaft.

Gould & Curry—increased in sales, but not in price during the week under review. For the week ending June 12th, the ore yield is reported at 546 tons, showing an average assay value of $51 37 to the ton; previous week, 401 tons were taken out. On the seventh station 16 feet have been added to cross-cut "A" during the week, running in hard blasting quartz, making the total length of drift 116 feet. From the fourteenth floor, 100 feet above the lower adit, an incline has been raised 44 feet, connecting with El Dorado level, showing quartz with small bunches of ore. The El Dorado winze is down 75 feet, and they have commenced drifting from it. The west drift in the United States tunnel has reached the west clay.

Belcher—is dull of sale at the decline. From the 3d to the 11th inst., 419¾ tons of ore were sent to the Rhode Island mill, showing an average assay value of $29 68. In the cross-cut going east on the 730-level, near the south line, a favorable change is said to have taken place. The May receipts of bullion aggregate $27,316.

Kentuck—under small sales has declined in price. For the week ending June 10th, 163½ tons of ore were extracted, yielding an approximate value of $3,377, equal to $20 65 per ton. The bullion yield for the month foots up $18,929.——**Crown Point** sold to a less extent than usual. During the week ending June 10th, 313 tons of ore were taken from the mine, the assay value being $5,594, or $17 87 per ton.——**Segregated Belcher** reports a bullion product of $15,835 for May, and $11,388 for account of the current month.

Overman—was in moderate request at a decline. The bullions returns for May aggregate $52,000.——**Sierra Nevada** sold at uniform rates. During the two weeks ending June 14th, 810 tons of ore were taken from the gravel deposits.——**Imperial** exhibits a decline. On the 13th inst. the bottom of the winze looked well, and they had encountered some fine ore in bunches. The 1,200 drift is in porphyry and clay. The southwest drift on the 1,100 level shows only quartz and phrphyry. Most of the quartz in this drift seems to run to the west, and they intend to carry a drift to the south line, and from thence cross-cut. Annual meeting, June 28th.——**American** levied an assessment of $3 per share on the 13th inst.

Hale and Norcross—sold at fluctuating rates, declining from opening rates of the week. During the week ending June 12th, 1,412 tons of ore were extracted, of which amount the seventh station yielded 794½ tons. The bullion returns for the month of May foot up $164,830. The ore-breasts on the third floor, lower level, have been partially opened, and are reported to look very well. In the cross-cut, 150 feet north of the shaft, the ore is 40 feet wide, and they have not yet reached the west wall.

Patents on the Pacific Coast.—To those of our friends who desire to keep posted upon inventions upon the Pacific coast we say, subscribe for the Scientific Press, published by Dewey & Co., San Francisco, Cal., at $4 per year. The opening of the railway across the continent has given to all patents a much higher value in that portion of our country known as the Pacific slope, and all interested will find the paper above alluded to a valuable reference.—*Mechanic and Inventor Detroit, Michigan.*

Farming and Gardening.

Communications for this department are solicited from all parts of the Pacific States and Territories.

Churning Butter—Fast and Slow.

Butter-making consists simply in breaking, by agitation, the envelopes of the little globules of butter, which rise to the surface of milk when at rest, and form a large portion of what we call cream. As soon as the envelopes are broken, the globules come in contact and adhere, forming masses of butter.

The excellence of butter is largely influenced by the temperature of the cream or milk during the process of churning. Experience has fixed this temperature, for the best results, at from 50° to 55° F. If the whole milk is churned, the temperature should not be allowed to fall below 55°; when only the cream is operated upon, four or five degrees lower is generally found advantageous.

In the process of churning, the agitation should be slow, until the cream has been "broken," or rendered thin. During this time considerable gas is evolved, the escape of which, from under the cover, will be noticed. When the gas no longer escapes, or when the cream has become thin, the motion should be slightly accelerated until a change in the sound is noticed, from low and smooth to a harshness of tone and an irregularity of resistance.

The butter may now be expected soon, and the motion should be still further accelerated, until the forming butter becomes sufficiently firm to impede the agitators, when the process should gradually be brought to a stop.

The rate of motion is of much importance; for if too slow, time is lost, and the butter acquires an unpalatable flavor; while if too rapid it will be soft and frothy.

It is often stated in the advertisements of patent churns that their use will cause the butter to come *quicker* than the use of any other. It will sometimes be said in as short a time as ten, eight, or even five minutes. If they accomplish their purpose in an unexceptionally short time, they will do it at the expense of the *quality* of the butter. Don't make shortness of *time* an important consideration in the working of a churn. Butter that has been made with thirty minutes churning is better than that which has occupied ten minutes in the process. Good butter is never obtained in less than twenty minutes.

Butter should always be removed from the churn as soon as formed. The sooner it is freed from the buttermilk by after-working the better.

Butter will come quicker from cream that has stood until it has become slightly acid than from that which is churned when perfectly sweet; probably because the acid so acts upon the covering of the butter pellicle as to allow it to be more readily broken.

Cream taken from milk in cold weather does not yield its butter so readily as that which is taken from the same cow in warm weather; probably because the coverings of the butter pellicles, formed in cold weather, are thicker than those formed in warm weather. It is said that this trouble may be obviated, in a great degree, by setting the pan as soon as the milk is strained, on a stove or in a very warm room for a short time.

How to Destroy Weeds.—The great means of destroying most kinds of weeds is to keep the leaves and stems from appearing, by frequent mowings or cuttings. Cutting them before the seeds have ripened is, of course, absolutely essential, but not always sufficient.

The grape crop of New Mexico will be unusually large the present season.

The Marvels of a Seed.

Having considered, in previous numbers, the organs of the flower, and the manner in which the seed is produced, we will now look for a few moments into the marvels of the seed. How many of our readers have ever considered the wonders inclosed in the seed of a plant? There is no machine, there is no device on earth, constructed by man, which contains so much that is wonderful as is found inclosed in a single grain of corn, or in a little apple seed. As we have not space to go into a detailed description of the various kinds of seeds, we will briefly summarize as follows:

The fruit comprises the seed-vessel and the seed itself, and constitutes the base of the pistil. It exhibits a great variety of forms, which constitute the different kinds of fruit. We have the nut fruits, the stone fruits, the pome or apple kinds, the berry or many-seeded fruits, the gourd or melon varieties, etc.

The grains are, properly, fruits, containing the seed and seed-vessels so closely united that they cannot be separately distinguished except after being soaked a day or two in water.

If we cut a kernel of corn lengthwise, we observe extending from the point where it was attached to the cob, the soft "chit," *b*, Fig. 1, which is the embryo, and its appendages, to be presently noticed. The remainder of the kernel, *a*, is called the endosperm, and is intended for the support of the young plant as it develops from the embryo, before it is capable of depending on the soil and atmosphere. It is not an indispensable part of the seed, and may be removed without preventing the growth of a plant.

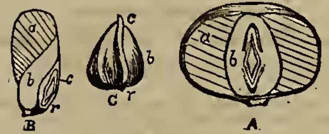

Fig. 1.

The embryo or germ, the most important portion of the seed, is a ready-formed plant in miniature, and contains within itself its root, stem, leaves, and a bud, although these organs are often as undeveloped in form as they are in size.

When a kernel of corn has been allowed to soak for a day or two in water, the embryo may be easily separated from the endosperm, and subjected to a careful inspection, as shown at C in Fig. 1. By careful manipulation it may in that condition be divided into three parts, which are called the *radicle*, the *plumule*, and the *cotyledon*. By the aid of a magnifyer the leaves, which subsequently appear above ground may now be seen wrapped together in the plumule. In Fig. 1 the embryo is seen imbedded in the endosperm, at A and B, while C exhibits the detached embryo. The *radicle*, *r*, is the rootlet of the seed-plant, or rather the point from which downward growth proceeds, from which the first true roots are produced. The *plumule*, *c*, is the ascending axis of the plant, the central bud, out of which the stem with new leaves, flowers, etc., is developed. The *cotyledon*, *b*, is in structure a ready-formed leaf, which clasps the plumule in the embryo, as the proper leaves clasp the stem in the mature maize plant.

The cotyledon of maize, wheat and other grains, the onion, all the grasses and many other plants is single, or in one piece; while that of the leguminous plants, as the bean, pea, clover, turnip, etc., the ordinary fruits, melons, and many forest trees, as the ash, maple, etc., is double or in two pieces or halves, as seen in Fig. 2.

Plants whose seeds have but one cotyledon are called *endogenous*, and are characterized by having their stems increase by *inside* growth; while those which have seeds with two cotyledons—or two halves—are called *exogenous*, and are characterized by an outside growth of the stem. We may best observe the structure of the latter by examining the ordinary bean. After a bean has been soaked in warm water for several hours, the coats may be easily removed, and the two fleshy cotyledons, *c*, *c*, in Fig. 2, will be found divided from each other, save at the point where the radicle, *a*, is seen projecting. On carefully breaking away one of the cotyledons, we get a side view of the radicle, *a*, and plumule, *b*, the former of which was partially and the latter entirely imbedded between the cotyledons. The plumule plainly exhibits two delicate leaves, on which the unaided eye may note the veins. These leaves are folded together along their mid-ribs, and may be opened and spread out with the help of a needle.

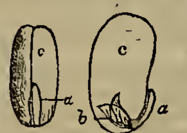

Fig. 2.

When the bean germinates, the cotyledons are carried up into the air, where they become green, and constitute the first pair of leaves of the new plant. The second pair are the tiny leaves of the plumule, just described, between which is the bud, whence all the subsequent aerial organs develop in succession.

In the horse-bean, as in the pea, however, the cotyledons never assume the office of leaves, but remain in the soil, and gradually yield a large share of their contents to the growing plant, shriveling and shrinking greatly in bulk, and finally falling away and passing into decay.

We shall next week endeavor to exhibit the anatomy of a grain of wheat, and follow the same by some remarks on the miracle of growth. We are again indebted to "How Crops Grow" for the accompanying illustrations.

Silk Culture in Santa Clara County. Mr. Jesse Williams, who was the first to introduce silk culture into Santa Clara county, commenced operations a little over two years ago, about seven miles from Watsonville. He has now three acres planted with mulberry trees, from which he is feeding 40,000 silkworms. The cocoons are large and fine looking, and the worms healthy. The success which has thus far attended the efforts of Mr. W. in this direction, is attracting others, in that vicinity, to this interesting and promising branch of industry.

We may remark, in this connection, that the silk crop in Los Angeles, this year, so far as already realized, is very superior. Indeed, the reports of silk-growers, generally, throughout the State, are highly encouraging. The mistakes and accidents of past seasons have been carefully guarded against, and the indications promise a large yield of superior silk.

Save the Horse Hides.—Horse hides are recommended in the Atlantic States in place of Buffalo skins, which are becoming scarce and high. A gentleman of Lee county, Illinois, writes to his local paper that he recently lost a colt and a mule; he had them skinned, and dressed the hides with the hair on, and would not give the mule-skin for any buffalo robe of the same size he had ever seen. The hide of a colt that has run out all winter has a thick, heavy coat of hair on it, and, if well tanned, makes a good robe.

The Stockton century plant has reached a height of thirty feet. Mr. Armington, who has charge of the grounds, says that the flowering stalk grew ten feet in fourteen days, or at the rate of a little over three-eighths of an inch per hour!

John at the Plow.—It is said that a Chinaman at the Oregon State Fair did the best plowing that was done upon the grounds.

The Santa Cruz Farmers' Club.

The Farmers' Club of Santa Cruz, at a meeting held on the 4th inst., discussed matters previously taken under consideration without coming to any positive action.

The report of a committee on the agricultural park and the establishing of an agricultural society with memberships, etc., was received, and, after some discussion, postponed till another meeting.

The present mode of assessing property in Santa Cruz county was also again discussed, and laid over to the next meeting, which will be held in the club room in the Court House, on the 18th of this month. I was not so fortunate as to be present at the meeting, but get my information from Mr. J. W. Morgan, the Secretary. J. S. Matteson is the President, and all the members are farmers; no others can belong to it. This is as it should be, as it will prevent any "ring" from controlling the voice of the club.

A Speculation.

Several of the business men in Santa Cruz have bought up a farm of 160 acres of fine land, within the city limits, and bordering on the bay, for the sum of $8,000. On one-half of it they have laid out a mile race track and the fair and park grounds. The balance they have laid out in five-acre lots, beautifully situated on the streets they have designed. They are now at work improving it, and mean to sell the lots for enough to clear the balance. Mr. Hihn assured me that this they would surely do. They have designed an agricultural society, and will sell life memberships for $50. It is to be presumed that the Farmers' Club are advising in the matter. It is purely their own business. What is for their interests, it is for themselves to determine.

Assessing Unimproved Property.

Whatever action the club takes upon the mode of assessing property, one thing is sure, unequal taxation is having a discouraging and damaging effect upon the industrial interests of this State. This is more especially the case with the land and agricultural interests. It is a well-known fact that large tracts of unimproved land are never assessed at anywhere near the real value, while as soon as a settler gets hold of a farm, up goes the taxes on the land. Every improvement is remorselessly taxed; every acre that is plowed, including the plow itself and the team and every product of industry, is taxed till the sweat of the brow strikes a chill to the very life of honest toil! The lands that miserable greed and corrupt speculation have robbed from the public domains, and hold as forbidden ground against the people, against industry, enterprise and civilization, are almost exempt from taxation, while the bone and sinew, the brain and enterprise, the useful and progressive, are taxed beyond endurance. The labor and the bread of life is made to drive and oil the expensive machinery of State, that monopolies may flourish. Every head of live stock that a farmer raises is heavily taxed, but the herds that overrun thousands of wild acres are lightly assessed. Where is the justice in taxing lands made valuable by the surrounding influences of industrial progress; lands kept out of market, or above the reach of settlers; lands kept unproductive by idle speculation, barren of good to the community, yet grown to a marketable value nearly or quite equal to the surrounding improved lands?

It is time that some decisive action was taken, that some virtuous measures were resorted to, that something was done in this matter. Land monopolies should be made to pay taxes to the full value of their lands. Unimproved land should especially be made to pay full taxes. If the owners cannot stand it, let them sell out to somebody that can; and the sooner they do that the better. And in order to encourage improvement and settlement of lands, at least eighty acres of every new farm should, if broken up with the plow, be exempt from taxation the first year of cultivation.

Although the Farmers' Club of Santa Cruz may not be equal to the task of regenerating and reörganizing the affairs of State, their influence will probably be cast on the side of justice and right. Some doubtful wiseacres think that they would do better to confine their discussions to the matters of what to grow and how to best cultivate it. While industry is the sufferer, it is right to wage war on the pestiferous evils that eat so large a share of prudence, as well as to consider the means of advancement in farming.

S. H. Herring.

Bones—How to Utilize Them—No 2.

In our last we showed how bones were reduced or ground by machinery and also how they might be so softened and rendered brittle, by a slow process of decomposition, as to be quite readily pounded up by hand, easily ground in a common bark mill, or sufficiently broken up by merely handling and turning over with a rake or shovel.

How to use Bones Softened by the Latter Process.

If the bones have been collected and mixed, as described, with stable manure and ashes in the spring or early summer, by the following spring they will be ready for use. When shoveled out of the heap, if the process has been thorough, the bones ought to be nearly as soft as chalk, and will need neither grinding nor pounding. Bones that have been thoroughly boiled, steamed or burned, will not decompose in the heap, so readily as *raw* bones; because most of the animal matter is removed in the process of boiling, and all of it in burning; while it is to the presence of such animal matter that the decomposition and fermentation is largely due.

Before applying the compost to the soil the heap should be shoveled or raked over, once a week, for three or four weeks, during which it would be well to add to the mass all the hen manure which can be conveniently collected. The process of raking or shoveling will often serve to disintegrate and pulverize the bones to an extent sufficient for immediate use.

In applying them to the soil put about a handfull of the compost to the hill, for corn, potatoes, squashes, melons, etc. If spread broad-cast, for grain, grass or other crops, double or treble that quantity may be used, and the beneficial effect therefrom will be seen for several years—more perceptibly the second and third than the first year. Its use will be found to increase and forward the crops wonderfully. There is an abundance of evidence that

Ground Bones Will Pay;

So also will bones treated in the manner above described. There is not an acre of wheat land in the State, the original yield of which is now materially less than when it was first cultivated; nor an acre which has been for a series of years devoted to culture of any kind, that may not be greatly benefited by a dressing of this kind. Thousands of acres of our best wheat lands, which are not now yielding more than half or one-third as much as formerly, may, by such dressing, be brought up to the original yield—and the value of the land thereby *doubled.* Other tracts of poor land, which have never yielded remunerative crops, might be made valuable by its application. Such fertilizing matter is the very life of the soil.

European farmers understand this, and import thousands of tons of bones annually, to be ground up and applied to their farms. Every ship-load that we thus part with works a positive injury to our agriculture, not a fourth part of which is repaid by the price obtained for the bones.

The Difference in Bone Manures.

We have already, in our article last week, made some reference to the difference between fine-ground bones, and those used in a coarser condition. The difference is only one of time. The finer the bones are reduced, the less and more frequent should be the amounts applied. But in the actual amount of fertilizing matter, finally utilized, there is no difference. The contrast is simply the time required for the money invested in the manure to come back. The finest floured bone acts as quickly as guano, and needs renewal as often. If bones are applied whole or coarsely broken, three or four wagon loads should be used to the acre. If ground, ten or twelve bushels will answer; which amount, however, if mixed with half the barn manure, generally, applied will be greatly increased in value, beyond the added cost of the barn manure. If the ground bones are dissolved in sulphuric acid, so as to form a superphosphate of lime (which will be hereafter described), three or four bushels only need be used, mixed with the same quantity of manure.

Ground bones or bone meal should be used in preference to the superphosphate, when the object is less to obtain prompt returns than to permanently increase the richness of the soil. Hence, for vines, trees, lawns, grass, etc., we should use ground bones; while for corn, root-crops, and perhaps for grain, where quick action is desirable, superphosphates may be most advantageously employed.

Bone Charcoal as a Manure.

Bone charcoal is made by heating bones in closed vessels, called retorts. The gases which pass off during the heating contain carbonate of ammonia; these are condensed in water. The liquid is then mingled with fine-ground plaster. This contains sulphate of ammonia and carbonate of lime. The liquid is then drawn off from the chalky carbonate of lime, and the ammonia salt is obtained by evaporation. The bones are now heated again to drive off the volatile substances. They are then broken down and pulverized, when they may be used as a fertilizer.

In our next issue we shall refer to the treatment of bones with sulphuric acid or the manufacture and use of superphosphate of lime.

A Fact for Farmers—Deep Plowing.

The Stockton *Republican* says: On the western side of the San Joaquin river, the wheat crop is a total failure this season. The whole surface of the country now presents a dry, parched up appearance, and the angel of death, in the shape of dry, hot winds, has desolated the grain fields. There is, however, one small oasis—a green spot in the desert—which greets the eye of the traveler, and gladdens the heart of the owner. About two miles from Banta's, and adjoining Peck's ranch, lie one hundred and sixty-three acres which are green and thrifty and promise to yield a fair crop. All around this field are miles of the same soil seeded in wheat, on which not a grain will be raised this season. Seed, soil and everything except the manner of seeding is similar yet his neighbors raise nothing, while A. P. Stocking has one hundred and sixty acres of fair wheat. The ordinary custom of sowing wheat is to plow the ground (a very shallow plow at that,) sow the seed and harrow it beneath the surface. Stocking pursued a different plan. He first deep or subsoil-plowed his ground; in the fall he re-plowed it and harrowed in the seed. In the spring the whole area was heavily rolled. The result is a fair crop, while ground seeded in the ordinary manner produces nothing.

Mount Hope Nurseries.—We have received from Messrs. Ellwanger & Barry, proprietors of the Mount Hope Nurseries, a copy of their catalogue of plants and trees for 1870, comprised in three numbers and profusely illustrated with well-executed engravings. The representation of the *Prunus Trilobata*, engraved on wood and printed in colors, is as fine a specimen of that style of printing as is often met with. This well known nursery is located at Rochester, New York, where it was established over thirty years ago. They have the largest and most complete stock of fruit and ornamental trees, plants, shrubs, etc., in the United States. Messrs. E. & B. were among the earliest to ship trees and plants to this State. Large quantities of trees were sent hither, via the Isthmus, in the early days of California. Llewellyn, Briggs, and many others of our pioneer nurserymen, obtained a large portion of their original stock from this establishment. Their long and intimate acquaintance with California's wants and taste and their knowledge of our climate, soil, etc., renders this house a most desirable one from which to order. See their advertisement in another column.

What I Know of Farming—No. 22.

Insects—Birds.

If I were to estimate the average loss per annum of the farmers of this country from insects at $100,000,000 per annum, I should doubtless be far below the mark. The loss of fruit alone by the devastations of insects, within a radius of fifty miles from this city, must amount in value to millions. In my neighborhood, the peach once flourished, but flourishes no more, and cherries have been all but annihilated. Apples were till lately our most profitable and perhaps our most important product; but the worms take half our average crop and sadly damage what they do not utterly destroy. Plums we have ceased to grow or expect; our pears are generally stung and often blighted, even the currant has at last its fruit-destroying worm. We must fight our paltry adversaries more efficiently, or allow them to drive us from the field. Now, I have no doubt that our best allies in this inglorious warfare are the birds. They would save us, if we did not destroy them. The British plowman turning his sod with a myriad of crows, blackbirds, etc., chasing his steps and all but getting under his feet in their eager quest of grubs, bugs, etc., is a spectacle to be devoutly thankful for. Whenever clouds of birds shall habitually darken our fields in May and (less notably) throughout the summer months, we may reasonably hope to grow fair crops of our favorite fruits from year to year, and realize that we owe them to the constant, and zealous, though not quite disinterested efforts, of our friends, the birds.

But I do not regard the ravages of insects as entirely due to the reckless destruction and consequent scarcity of our birds. I hold that their multiplication and their devastations are largely incited by the degeneracy of our plants caused by the badness of our culture. On this point, consider a statement made to me, some fifteen or twenty years ago, by the late Governor William F. Packer of Pennsylvania: "I know (said Gov. P.) the narrow valley of a stream that runs into the west branch of the Susquehanna, which was cleared of the primitive forests some forty or fifty years since, and has ever since been alternately in tillage and grass. A road ran through the middle of it, dividing it into two narrow fields. A few years ago this road was abandoned, and the whole of this little valley, including the roadway, thrown into a single field, which was thereupon sown to wheat. At harvest-time, this remarkable phenomenon was presented: A good crop of sound grain on the strip four or five rods wide formerly covered by the road; while nearly every berry on either side of it was destroyed by the weevil or midge."

Now I do not infer from this fact that insect ravages are *wholly* due to our abuse and exhaustion of the soil. I presume that wheat and other crops would be devastated by insects if there were no slovenly, niggard and exhausting tillage. But I do firmly hold that at least half our losses by insects would be precluded if our fields were habitualy kept in better heart by deep culture, liberal fertilizing, and a judicious rotation of crops. I heard little of insect ravages in the wheat-fields of Western New York throughout the first thirty years of this century; but when crop after crop of wheat had been taken from the same fields until they had been well nigh exhausted of their wheat forming elements, we began to hear of desolation wrought by insects; and those ravages increased in magnitude until wheat culture had to be abandoned for years. I believe we should have heard little of insects had wheat been grown on those fields but one year in three since their redemption from the primal forest.

But, whatever might once have been, the Philistines are upon us. We are doomed, for at least a generation, to wage a relentless war against insects multiplied beyond reason by the neglect and shortcomings of our predecessors. We are in like condition with the inhabitants of the British Isles a thousand years ago, whose forefathers had so long endured and so unskillfully resisted invasion and spoliation by the Northmen that they had come to be the regarded as the sea-kings' natural prey. For generations, it has been customary hereabouts to slaughter without remorse the birds, and let caterpillars, worms, grasshoppers, etc., multiply and ravage unresisted. We must pay for past errors by present loss and years of extra effort. And, precisely because the task is so arduous, we ought to lose no time in addressing ourselves to its execution.

The first step to be taken is very simple. Let every farmer who realizes the importance and benificence of birds teach his own children and hirelings that, except the hawk, they are to be spared, protected, kindly treated, and (when necessary) fed. They are to be valued and cherished as the voluntary police of our fields and gardens, constantly employed in fighting our battles against our ruthless foes. The boy who robs a bird's nest is robbing the farmer of part of his crops. He who traverses a farm shooting and mangling its feathered sentinels diminishes its future product of grain and nearly destroys that of fruit. The farmer might as well consent that any strolling ruffian should shoot his horses or cattle as his birds. Begin at home to make this truth felt and respected, and it will be the easier to impress it also on your neighbors.

Next, there should be neighborhood or township associations for the protection of insect-eating birds. We must not merely agree to let them live—we must cherish and protect them. I believe that very simple cups or bowls of cast iron, having each a hole in its center of suitable size, that need not cost sixpence each, and could be fastened to the side of a tree with one nail lightly driven, would in time be adopted by many birds as nesting strongholds, whence they might laugh to scorn their predations enemies. If every harmless bird could build its nest among us in a place where its eggs would be safe from hawks, crows, cats, boys, and other robbers, the number of such birds would quickly be doubled and quadrupled.

And we must summon the law to our aid Though law can do little or nothing against stealthy, skulking nest-plunderers, it can help us materially in our warfare with the cowardly vagabonds who traverse our fields with muskets or rifle, blazing away at every unsuspecting robin or thrush that they can discover. Make it trespass, punishable with fine and imprisonment, to shoot on another's land without his express permission, and the cowardly massacre of the farmer's humble allies would be checked at once, and, when public sentiment had been properly enlightened, might, in civilized regions, be arrested altogether.—*Horace Greeley.*

Value of Salt Marsh Land.—The *Call* of recent date says: "We have seen some beautiful specimens of timothy grass, wheat, oats, and alfalfa, grown upon salt marsh lands only six months redeemed from the waters of the Bay. These were grown on the marsh lands of Captain H. Powers, Lakeville. The wheat and oats are about three to three and a half feet in length, and the grasses and clover are healthy, stout, and vigorous in appearance. All of these products compare favorably with upland crops, and yet they are produced from soil so lately under the influence of the waters of the Bay that one can taste the salt in the juices of the wheat by biting the stalks. This result is certainly very encouraging to parties engaged in reclaiming the marsh lands around our Bay."

Rust.—The Russian River *Flag* says that the rust is making its appearance in the wheat of that section.

Notices to Correspondents.

J. D., Oroville.—The substance used for enclosing small packages of tobacco, and called tin foil, is generally a compound of about equal parts of tin and lead. There is no silver in it. It is not an "amalgam," but an alloy of the two metals. The experiment you tried of melting a small quantity and running it into bars, and bending the same, is conclusive with regard to its being largely alloyed; as commercially pure tin, when beaten or bent, produces a crackling sound peculiar to that metal. We know of no way in which tin, so alloyed, can be profitably separated. The use of tin foil, adulterated with lead, as a wrapper for tobacco, spices, etc., is very pernicious.

W. H. B., Washington, D. C.—Machinists' wages in San Francisco range from $2.50 to $4 per day (gold). Business in that line is dull here at present, and there is little chance for new-comers to get employment, except through some particular friend, who may be either an employer or one having influence with employers. We do not know of any person in this city by the name of Peter Brooks—no such name appears in the Directory.

THE GRAPE VINE INSECT.—With regard to this insect, received from a Santa Cruz correspondent, we failed to identify it by any authority within our reach, and handed it over to a competent entomologist, from whom we had expected a report in season for to-day's issue; but failing in that, we are compelled to defer an answer until next week.

F. G. McD., Chinese Camp.—We do not know what furnace is referred to unless it is the Mosheimer, lately illustrated in our paper, which we send you. There is an indefinite number of furnaces which are claimed as wonderful inventions. Can you not find out the name of the furnace in question?

COPE DISTRICT.—Several interesting letters on the mines of this and other districts, from W. H. M., will appear in the following issues.

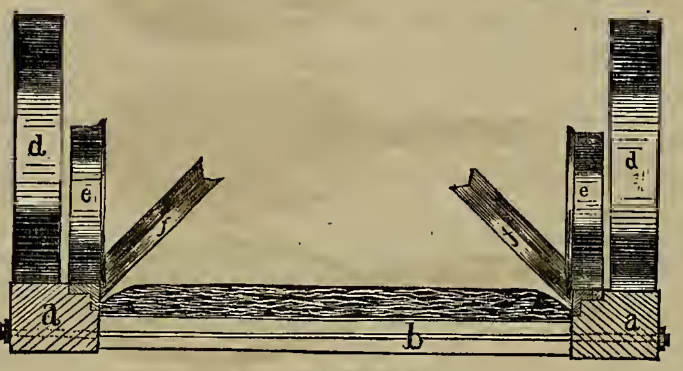
METALLIC SOAPS.—An article on this subject, by E. P., will be published as soon as possible.

LEATHER.—Last week Mr. C. F. Crist shipped, from Marysville, six tons of leather, which has been tanned in Butte county, for the Boston market. We hope that we may be able, at no distant day, to manufacture and work up the article on our coast. We see no real reason why we should not

Tram Railways.

The necessity of some means of cheap transportation, by which out-lying towns and districts can be brought into direct communication with other places and with existing railway systems, has long attracted the attention of engineers. That an efficient method of the kind would be of incalculable benefit to the mining and agricultural regions of California and her sister States and Territories, has been deeply felt. Could the toilsome and expensive hauling by heavy teams be replaced by transportation on a simple railway which requires no costly bridges, cuttings, tunnels or embankments, the mining interests would receive immense advantages; and could the distant farmer in the same way be enabled to bring his produce quickly and cheaply to the large markets, both producer and consumer would immediately be greatly benefited. Cheap avenues would bring into demand many fair regions now too far removed from any available center, and immigration would be attracted in large numbers.

We have spoken repeatedly at different times on this all-important topic, and have illustrated a few of the plans proposed by various parties, some more and some less promising. We give to-day a drawing of the system of the Tram Railway Company of Great Britain. This company intends introducing their system into our State, and have already appointed as their agent here, Mr. P. B. Lewis, of Alleghany, Sierra county, Cal.



TRAMWAY FOR BRANCH ROADS.

The manner in which the road is built and run, can be illustrated by a simple cut In the drawing, *a* represents the trams of iron, stone or timber, laid lengthwise along the road, and prevented from spreading apart by bolt-rods, *b*. On these timbers run the driving-wheels, *d*, of the locomotive, which are made from six to eight inches broad, and slightly serrated, so that in this way, and from the roughness of the tram, sufficient adhesion or "bite" is obtained to enable the locomotive to ascend steep gradients with heavy loads. On the inner edge of the tram is fixed a rail, *c*, two inches wide and an inch thick, on which the carriages run with flanged wheels, *e*, as in ordinary railroads.

There are no flanges on the locomotive driving-wheels, *d*, but the engine is furnished with vertical or diagonal guide-wheels, *f*, bearing against the inner edge of the tram, and keeping the locomotive on its proper line. The locomotive will resemble an ordinary road wagon, and will be free from the disadvantage of the noise of steam escaping from the blast-pipe, whistling, etc. The steam will be expanded in the cylinders, being cut off at one-eighth of the stroke on a level, and only worked at full pressure when going up a steep incline.

The cost of such a road in England is stated to be from one-eighteenth to one-twentieth of the cost of existing railways there, including purchase of land, etc. Of course the ratio is more in favor of the tramway in hilly and less in level country (leaving the value of land out of the question), on account of cuts, tunnels, etc., necessary in the ordinary system.

Experiments have been tried in England on a model railway, about one-sixth of the full size, before a number of prominent engineers and army officers. At one of these, as we are informed, the ascent of a gradient of one in ten was successfully performed. At another, with a locomotive worked by a spring, the grade was one in four; again it was one in three; and finally it is said that the extraordinary result was obtained of the ascent of a gradient of one in two and a half. The latter experiments were made simply to show what could be accomplished by the fact of adhesion between the driving wheels of the engine and the surface of the tram. Of course no such inclines are known in railway practice, nor do we believe that any real load could be successfully carried up such as the last, except on models; but the experiments still denote extraordinary powers of great importance.

According to these, the road can have severe gradients, and hence a common road can be used. The company propose to lay their tracks on such roads whenever there is sufficient inducement that the traffic will pay. Their track will present no danger nor inconvenience to ordinary vehicles, and will make no obnoxious noises, as whistling, etc. They will either run the roads themselves or lease them to other companies, and will also grant licenses for the construction and use of lines under their patents. The system, or the principal part, was invented, we believe, by Thomas Page, of London, engineer of Westminster Bridge, etc. We should be glad to hear of its being in successful use in our State. Some such system is certainly greatly needed by the whole coast. We understand that the agent, Mr. Lewis (address as above), is preparing to take active measures for its introduction, and thinks that he is sure of success if he gets a fair trial.

ROASTING OF GOLD AND SILVER ORES, and the extraction of their respective metals without quicksilver. Under this title we shall soon publish an excellent work by Mr. Guido Küstel. The reputation of the author renders unnecessary any further recommendation of the work, which will be a clear and complete treatise on these subjects, which are of so much interest at the present time. Miners and others will find it of great value. The various methods and furnaces employed in roasting, and the processes of chlorination and lixiviation with the different manipulations and apparatus, will be fully described, and amply illustrated, together with remarks on the various advantages and disadvantages of each process, and their special application on this coast.

FINE BARLEY.—Mr. Beighley, of Sutter county, recently exhibited at the office of the Marysville *Appeal* thirteen stalks of barley—the Florida White. Three of the heads measured, each, five and one-half inches; while the aggregate length of the thirteen was four and one-quarter feet. The heads were all well filled.

THE GRASSHOPPER PEST.—Farmers and orchardists in several portions of the State are being quite seriously troubled with grasshoppers, which are doing much damage to growing crops, trees, etc. Several extensive neighborhoods in Placer, Tuolumne, Merced, Mariposa and Los Angeles counties have been visited by these pests. In the latter county, on several ranches, mustard, live fences, and indeed every green thing which they could conveniently reach, was destroyed by them. At Currie's ranch, in Placer county, they came in such dense numbers that the proprietor had to close up his house and chink it with rags to keep the insects from taking possession thereof. They do not attack ripened grain, etc., having a taste for something greener and more juicy. They appear to travel in large swarms, and when in sufficient numbers, destroy anything green that comes in their way. At one locality they encountered a well, into which they drifted in such numbers as soon to render the water unfit for use. Rivers, and wide and swiftly-running mining or irrigation ditches, generally stop or turn them. As a general thing, we believe, they are comparatively wingless, or, at best, with wings but imperfectly developed.

CINCINNATI INDUSTRIAL EXHIBITION.—An exhibition of Manufactures, Products and Arts will be opened in Cincinnati on the 21st of September. The managers cordially invite manufacturers, mechanics, artists, agents, inventors and others to contribute specimens of their skill, ingenuity and taste.

A very large building is to be erected, steam power will be provided for machinery, ample arrangements will be made with the various railways, steamboats and other lines for transporting visitors and articles for exhibition, and handsome and numerous premiums and awards are promised. The exposition is held under the auspices of the Chamber of Commerce, the Board of Trade and the Ohio Mechanics' Institute. Parties intending to contribute to it are requested to give early notice of the articles, amount and kind of space required, to the "Secretary of the Cincinnati Industrial Exposition."

THE BEET SUGAR enterprise, in charge of Messrs. Otto, Klind and Bonesteel, will go into active operations about the first of August, or as soon as the beet crop comes in. The mill is already in course of erection, near Alvarado, and machinery capable of working fifty tons of beets per day is now in progress of construction at the Union Foundry. The cost of the mill and machinery will be about $75,000. The company go into operations with a capital of $250,000, and will employ from 100 to 150 men. The manufacture of sugar from beets ought to form one of our most available and profitable branches of industry. The waste products or pulp, after the saccharine matter has been extracted, affords excellent food for cattle and hogs, and will be found especially serviceable for use by the dairy establishments, from which this city is supplied with milk.

LESSONS IN ASSAYING.—We observe that Mr. H. G. Hanks, of the Pacific Chemical Works, has decided to devote a part of his time to teaching mineralogy and blow-piping. We are well acquainted with Mr. H., and can certify that he knows that which he teaches. Hence, we are cordially willing to recommend him to those desirous of gaining a knowledge of the determination of minerals and the use of the blow-pipe.

AN INJUNCTION on the Mercantile Library Gift Enterprise was applied for last week by Daniel O'Connell. The case came up before Judge Morrison, who denied the injunction.

Patents and Inventions.

A Full List of Patents Issued to Pacific Coast Inventors.

[From Official Reports to DEWEY & CO., U. S. and Foreign Patent Agents, and Publishers of the Scientific Press.]

For the Week Ending June 7th.

Pneumatic Gas Machine.—David Boyle, San Francisco.

Steam Ram.—Thomas Hill, Vallejo, Cal.

Baling Press.—Enoch J. Marsters, Shaws Flat, Cal.

Printing Press.—Amos H. Bangle, Brooklyn, Cal.

Note.—Copies of U. S. and Foreign Patents furnished by Dewey & Co., in the shortest time possible (by telegraph or otherwise), at the lowest rates. All patent business for Pacific coast inventors transacted with greater security and in much less time than by any other agency.

◆

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co's Scientific Press American and Foreign Patent Agency, the following are worthy of mention:

Steam Ram.—T. Hill, Vallejo.—The late war gave to the invention of offensive and defensive means of warfare an impetus which is still felt. The invention here spoken of belongs to this category, and relates to an improved ram for piercing a hole in the side of iron-clad and other vessels below the water-line, and the iron casing or shield. The vessel in which this is placed is protected with armor-plate, and ordinarily stands with its deck clear above the water; but when prepared for action, it is sunk by admitting water into proper compartments, until but a small portion of the deck is visible. At the bows is placed the offensive apparatus. This consists of a ram which is worked by a proper engine. This ram consists of a steel tube, 24 feet long, 16 inches in diameter, and having an 8 inch bore, the outer end being tapered to an edge, and the bore decreasing for about eight inches from the outer end, so as to be easily cleared of obstructions by the shell. This tube extends out through the front edge of the vessel below the water-line, and below the line of plating of vessels, being kept water-tight by a stuffing-box. It is so constructed that a shell may be placed in it and exploded at the instant the ram pierces the opposing vessel. An indicator gives warning when the ram is near an opposing ship, lights the fuse and lets on steam, driving the ram forward with enormous force. The driving piston can make upwards of 40 strokes per minute, and, if desired, the side of the vessel attacked may be pierced with many holes before separating.

Pneumatic Gas Machine.—David Boyle, S. F.—If the present and future generations are not amply supplied with good, cheap and sufficient light, it will not be the want of attention on the part of inventors. Victor Hugo, in his works, is continually crying for "more light." According to appearances, he will soon be able to find enough if he visits our coast. The device of Mr. Boyle relates to an improved gas-machine of that class in which air is carbureted or charged with the vapor of gasoline, naphtha, or other similar hydro-carbons. It consists in combining, in one vessel, a meter drum, or air-supplier, an air-reservoir, and a carbureting apparatus, in such a manner that air is supplied in a regular current and deprived of its moisture before it enters or comes in contact with the gasoline, so that the latter is not weakened or diluted with water. After being thus dried, the air passes through the different chambers over the surface of the gasoline, and is thus saturated with the vapors and rendered fit for the purposes of illumination.

Improved Printing Press.—A. H. Bangle, Brooklyn, Alameda Co.—It is certainly a matter of pleasure to record any invention which aids in the dissemination of knowledge. Nor should one pass by unnoticed any effort in this direction, however slight it may appear to be. Any simplification or complementary device is a step towards the better education of the masses, and as such should be cordially received. The invention in question is an improvement in the automatically inking printing press, and may be operated by hand or other power; or it can be used as a simple, cheap press to ink by hand, without the combination of rollers. It can be used for any kind of printing, but is more especially intended as a job-press for small work, and, being cheap in construction and complete in all its parts, is particularly suitable for tradesmen and professional persons, who require large numbers of labels, cards, circulars and other similar printing matter.

◆

Important Invention.

A caveat has recently been filed through the Scientific Press Patent office for a variable cut-off for side lever or puppot-valve engines, such as are in general use on high pressure steamers. This is the invention of Mr. W. B. Cross, Chief Engineer of the California Steam Navigation Company. It has been tried practically on the steamer Chin-du-Wan and has proved a complete success, according to the Sacramento *Union*, which comments on it as follows:

It is in a line of invention to which belongs nearly all the modern and practical improvements in the steam engine, namely, economy of fuel. It is a desideratum long sought by all builders and workers with this class of engines, and having been put to a practical test for several trips on the Chin du-Wan, may be pronounced a complete success. The invention consists simply of an arrangement for opening and closing the receiving valves at any desired part of the stroke of the piston, in order to use only the natural expansion of the steam for the remainder, which, in engineering parlance, is termed "cutting off." So completely does this arrangement accomplish this object that the steam may be cut off at every three inches of the entire stroke.

Like most practical inventions, this one is extremely simple, and only needs to be seen by practical engineers to be appreciated. The side lever or puppet valve engine, with an adjustable cut-off, becomes at once if not the most, certainly one of the most, manageable and convenient for river steamers in use. Usually it is built to cut off a given point for general use, and then, when necessary to work it full stroke, the valves are raised by hand or by placing a block of wood between the lever and the cam which raises it. This invention places the matter of using much or little steam, as required, entirely in the hands of the engineer.

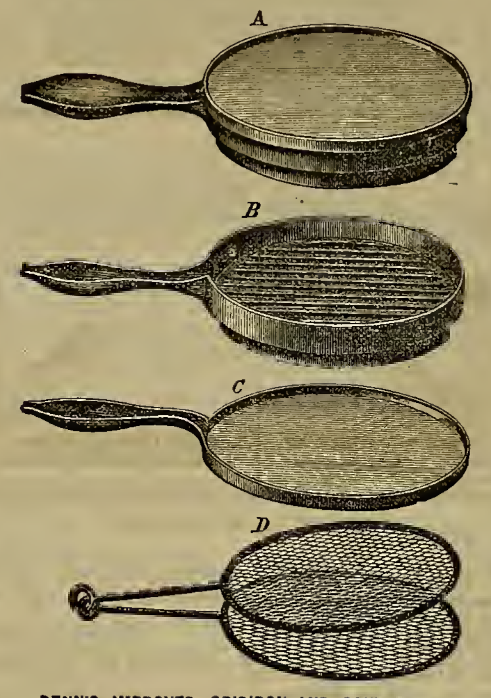
◆

Tea.—Mr. Henry Schnell, of the El Dorado Japanese colony, was in Sacramento last week with samples of tea grown and cured at his plantation three weeks ago, it is said. The article was pronounced of excellent quality, although, as it seems to us, it must have been rather young for use. He afterwards came to this city, and we had the pleasure of seeing him at our office and of talking over agricultural and other matters with him.

Denn's Improved Gridiron and Cake Baker.

It is very possible that it is not so much ignorance of the deleterious effects of fried meats as the want of proper appliances for broiling, which induces housekeepers to adopt the former method to such an extent. Physicians have long spoken authoritatively against frying in grease, and travelers in the United States have written against it, but still this is still astonishingly common.

Broiling is a most wholesome and preferable mode of cooking. To enable this to be done well and to obviate such inconveniences as the smoking of walls, the dripping of grease, etc., is the object of the present invention. This consists of three principal parts. The gridiron, B, its cover, C, and the wire gridiron, D, which may be used inside of the other when it is desired to broil food which would fall through the bars of the other, such as oysters; or it may be used as a corn popper or bread toaster.



DENN'S IMPROVED GRIDIRON AND CAKE BAKER.

The cover may be used as a cake baker by placing it on the top of the stove with the hollow side of the handle up. It will be seen by an inspection of the engraving that the gridiron has a rim or projection on its underside to rest on the ledge in the hole of the stove or range, the rim being narrower at the part toward the handle, for the purpose of giving the bars an inclination in that direction, to cause the gravy to flow out into the hollow handle and be saved for use. It will also be seen that the device when in use makes an air-tight cover to the hole, preventing the escape of smoke into the house and keeping up the draft in the stove.

The sizes range from No. 6 to No. 10, inclusive, and are made to fit the corresponding numbers of stoves and ranges. They may also be made oblong so as to occupy both the openings over the fire-space, being more convenient for large families or restaurants in that form.

This device was patented June 23d, 1868, by Clayton Denn, of Frankford, Pennsylvania, who will sell the right for all the States and Territories west of the Rocky Mountains, including Montana, Colorado and New Mexico. For further particulars apply to Wiester & Co., 314 Bush street, San Francisco.

◆

California Blankets at the East.—W. H. Aspinwall, the well known merchant and ship-owner of New York, one of our Eastern visitors, has given large orders for blankets to be filled by the Pioneer Woolen Mills of this city, and the Willamette Woolen Mills of Oregon. California and Oregon blankets are in high estimation at the East.

The Johnson Distilling Process.—Efforts are being made, says the Marysville *Appeal*, to organize a company at Oroville, to distill brandy from grapes by the Johnson process, a California invention. Capt. James Ganley, of this city, who is interested in this patent, is in the enterprise, and proposes, in case 1,000 tons of grapes can be purchased annually in that vicinity, to organize with a capital of $75,000. The Johnson process has been very fully discussed and thoroughly tested. It is no longer an experiment. Its chief feature is the production of good brandy at a single distillation, without carrying over either fusel oil or other foreign substances to an injurious extent. By this process it costs no more to make a brandy that will readily command three or four dollars per gallon than it does to produce the poor stuff usually manufactured in this State, and which sells with difficulty for less than half that sum. The plan of organizing companies of this kind to secure a market for our rapidly increasing grape crops is what is needed in California. A similar company has already been organized in Nevada, and measures are being taken to organize one in Placer. It is proposed to pay one cent per pound for the grapes, delivered, we presume, at the distillery. At such prices grapes will net two or three times as much per acre as land devoted to wheat or barley; while the market for such products is unlimited.

◆

Mining Education.—It is often brought forward as an argument against mining education, that every mine of value in this and neighboring States or Territories has been discovered by "practical" or "ignorant" men. This is no argument at all, for it does not by any means disprove that these very men would have discovered the mines had they been educated. Nor is the statement altogether true. For instance, we find in an article in an interior paper, the tendency of which is to disprove of mining education, the announcement that the silver ore of the Comstock ledge was discovered by "very ignorant men who had never seen silver ore before." Now it happens that these "ignorant men" who were looking for *gold*, had been *throwing away* the valuable silver ore, which was recognized by an educated man and a mining engineer of considerable note, namely, Mr. Melville Atwood, at that time at Grass Valley.

◆

Southern Pacific Railroad Subsidy.—The official recount by the Board of Supervisors shows a majority of 62 votes in favor of the subsidy, instead of 124 against it, as given by the first count. But it appears, moreover, that a number of votes *against* were altered to read *for*, and this change seems to have been fraudulently done. But positive proof of fraud has not yet been obtained, and judgment should be suspended until the case is thoroughly investigated, although it looks dark at present.

◆

The Beethooven Festival at New York commenced on the afternoon of the 14th inst. The chorus is reported as 1,500 strong and the orchestra numbers 100 instruments. The festival is held in the Institute Building or Empire Rink. Madame Parepa-Rosa took the solo parts. The building was filled to overflowing. An ovation was given to Gilmore and Parepa-Rosa. The latter sang "The Star Spangled Banner" with a chorus of 300 voices.

◆

That Wheel.—Mr. John Pattison, of Nevada, has sent to the Mercantile Library Association the model of a wheel, which he thinks is bound to take the $500 premium offered by that Association. "Pat" generally wins when he goes after anything.

◆

Rider's Automatic Cut-Off Vertical Engine will be illustrated in the next number of the Press.

Professional Cards.

JOHN GORMAN,
NOTARY PUBLIC.
COMMISSIONER FOR
Nevada, New York, Etc.
No. 612 MERCHANT STREET. 6v20-3m

JAMES M. TAYLOR,
Attorney and Counsellor at Law,
Court Block, 636 Clay Street
SAN FRANCISCO.

JOHN ROACH, Optician,
Has removed from 522 Montgomery street to
540 Washington street,
East of Montgomery.
Surveying Instruments made, repaired and adjusted
22v17-3m

GILES H. GRAY. JAMES M. HAVEN.
GRAY & HAVEN,
ATTORNEYS AND COUNSELORS AT LAW,
In Building of Pacific Insurance Co., N. E. corner California an Leidesdorff streets,
27v16 SAN FRANCISCO.

REMOVAL.

DR. BEERS, Dentist,
Has removed from Tucker's Building to No. 109 Montgomery street, three doors north, opposite the Occidental. 2v20-3m

Dr. J. H. PAINE, Dentist,
Wadsworth House, No. 225 Bush street, between Cosmopolitan and Occidental Hotels, San Francisco.

DR. J. P. GILLESPIE, D. D. S.,
DENTIST.
OFFICE, 313 BUSH STREET, NEAR MONTGOMERY.

Is a regular graduate, with twenty years experience in practice. 14v20-3m

Business Cards.

A. H. JORDAN,
Architect, Designer and Draughtsman,
No. 430 Montgomery Street,
SAN FRANCISCO. 16v19-qy

Farmers and Mechanics
BANK OF SAVINGS,
No. 225 Sansome Street.

Interest paid on Deposits. Money Loaned on Real Estate.
H. DUTTON, President.
GEO. M. CONDEE Cashier. 19v16-3m

NATHANIEL GRAY. H. M. GRAY.
N. GRAY & CO.,
UNDERTAKERS,
641 Sacramento St., cor. Webb, San Francisco.
☞Sole Agents for Barstow's Metallic Burial Cases and Caskets.
25v14tf

J. HOOVER,
PUBLISHER,
And Wholesale Dealer in
Fine Chromos and Lithographs.
The Largest Assortment in Philadelphia.
WHOLESALE DEPOT:
No. 804 Market Street, Philadelphia, Penn.
9v20-6m

C. B. FETY,
SEAL ENGRAVER
AND LETTER CUTTER.

Seals, Brass Stamps, Steel Punches, etc. Orders by express promptly attended to. No. 622 CLAY STREET, bet. Kearny and Montgomery, San Francisco. 23v20-3m

PIERRE A. FORTIER,
Practical Optician
105½ Montgomery Street, up stairs.
The only manufacturer in the United States who can make Glasses adapted to any imperfection of sight. Prices very moderate. 24v20-3m

Trades and Manufactures.

WM. BARTLING. HENRY KIMBALL.
BARTLING & KIMBALL,
BOOKBINDERS,
Paper Rulers and Blank Book Manufacturers.
505 Clay street. (southwest cor. Sansome),
16v12-3m SAN FRANCISCO.

J. F. PAGES,
SEAL ENGRAVER,
AND LETTER CUTTER.
Brass and Steel Stamps and Dies, **608** Sacramento street, San Francisco. Orders by express promptly attended to.

California File Manuf'g Co.
437 BRANNAN STREET, bet. Third and Fourth.
W. WUSTHOFF, L. KRAMER, M. HARRIS, J BURKE.

REAPER AND MOWER SECTIONS, BARS AND KNIVES COMPLETE,

At a saving of 50 per cent. New Files of every description on hand and made to order. Old Files re-cut, and warranted equal to new. Orders from the country promptly attended to. 9v19-qy

SAN FRANCISCO MILL.
HOBBS, GILMORE & CO.,
Manufacturers of Boxes,
Market Street, bet. Beale and Main.
For sale—Mahogany, Spanish Cedar, and other Woods.

J. M. STOCKMAN,
Manufacturer of
PATTERNS AND MODELS,
(Over W. T. Garratt's Brass Foundry,
S. E. Corner of Mission and Fremont sts.,
6v14tf SAN FRANCISCO

L. SCHUMANN,
PIONEER
Meerschaum Pipe Manufacturer,

No. 341 KEARNY STREET,
Between Bush and Pine streets, San Francisco.

The first and only Manufactory on the Pacific Coast. MEERSCHAUMS MOUNTED WITH SILVER. Meerschaum Pipes Boiled and Repaired. Amber Mouth-pieces Fitted.

D. BOYLE. JOHN BENN. M. BURKE.
AMERICAN MILLS,
Nos. 30 and 32 California Street.
Job work of all kinds in the Drug and Spice Line promptly attended to.
SECOND DEPARTMENT.—Feed Ground. Corn Meal, Oat Meal, Graham Flour, etc., constantly on hand. 7v206m

SAN FRANCISCO
CORDAGE COMPANY.

Manila Rope of all sizes. Also, Bale Rope and Whale Line constantly on hand. Mining Ropes of any size and length manufactured to order.
TUBBS & CO., Agents,
26 611 and 613 Front street.

F. SCHOENER,
METAL SPINNER.

All kinds of Metal spun to order. Give me a call at No. 10 STEVENSON STREET, fourth story Pioneer Mills.
14v20-3m

NOTICE.
HYDRAULIC HOSE MANUFACTORY.

Hose made to stand any pressure—from 100 to 300 foot fall. Miners are invited to call and examine my work. Tents, Awnings, Specie and Ore Bags made to order, and cheaper than any other factory. A share of patronage is solicited from my friends. [16v20-3m] S. HOWARD, 424 Davis st.

A. J. HAIGHT,
Gold Pen Manufacturer,
315 Montgomery Street.
Room No. 16, up stairs, San Francisco.
GOLD PENS REPAIRED. Watches, Clocks and Jewelry repaired and warranted. 8v20-6m

SAN FRANCISCO
PIONEER SCREEN WORKS,
JOHN W. QUICK,
No. 203 Fremont Street, near Howard.
Screen Punching of all kinds and qualities for Quartz, Cement, Flour and Rice Mills, at Eastern prices. 10v20

THE GIANT
POWDER COMPANY.
BANDMANN, NIELSEN & CO.,
General Agents,
No. 210 Front Street, San Francisco. 25v19

M. M. COOK. H. N. COOK.
M. M. COOK & SON,
MANUFACTURERS OF
LEATHER HOSE,
Belting, and Horse Collars,
801 Battery street, Corner Broadway,
SAN FRANCISCO.
☞ Belt Leather for sale. 26v19-3m

THEODORE KALLENBERG,
Machinist, and Maker of Models for Inventors.

All kinds of Dies, Stamps and Punches made. Also, all kinds of Small Gears cut. Repairing done on very reasonable terms, and in the best manner. ☞ No. 10 STEVENSON STREET, near First, Pioneer Mills. 26v19-3m

OSCAR LEWIS. J. H. CULVER.
LEWIS & CULVER,
Pattern and Model Makers
20 Fremont street, over Phœnix Iron Works.
Manufacturers of Models for the Patent Office, in wood or metals, and all kinds of Experimental Machinery. 1v20-3m

"ENTERPRISE"
SAWING AND PLANING MILL.

D. A MACDONALD, J. H. MACDONALD,
JOSEPH MCGILL, H. CHAPMAN.

D. A. MACDONALD & CO.,
Manufacturers of DOORS, SASHES, BLINDS AND MOULDINGS, 217 to 226 Spear street, and 218 to 226 Steuart street, between Howard and Folsom, San Francisco. ☞Finishing Work for buildings constantly on hand and got up to order. 20v20-3m

EXTRACT from a letter dated St. Louis, Mo., March 1, 1870: "MESSRS. DEWEY & C.:—The Scientific Press has been received. Though I am a constant reader of the Scientific American and great admirer of it, I confess my surprise on discovering the Pacific slope in possession of its equal in every respect. A. J. K." (inventor).

Metallurgy and Ores.

MINING SCHOOL.

Mosheimer's Practical Mining School

Will be reopened by the FIRST OF JUNE, and practical instruction given in all branches of Assaying, Crushing, Amalgamating Concentrating, Smelting and Refining Ores; also Erecting Furnaces and Reduction Works of every kind. To give all miners a chance to learn Assaying of Ores (what everyone ought to) I have reduced my former charge for

Assaying Ores	$ 50.00
To work Gold and Silver Ores	100.00
Smelting and Refining, including Assaying	150.00

Many gentlemen who have been taught in my establishment will bear testimony that in a few days they learned more than they expected to learn in a month. Before going into mining, every man ought to know how to test ores, and then he will go to work with prudence and never fail to be successful. Apply to
J. MOSHEIMER,
Office, 328 Montgomery street; Works, 2,005 Powell street, San Francisco. 22v23-3m

A. T. GREEN,
COMMISSION MERCHANT,
No. 3 Front Street. San Francisco.
Agent for SAMPLING, CRUSHING, ASSAYING and SELLING OF ORES Shipments received from miners, and the entire business transacted with promptness and accuracy. MERCHANDISE of all descriptions purchased and shipped on Commission for Country Merchants. Consignments of PROVISIONS received and sold at the highest market prices.
Refers, by permission, to Jas. Linforth, of Linforth, Kellogg & Co.; Jona. Hunt, Prest. Pacific Insurance Co.; A. J. Ralston, Sec. Pacific Insurance Co.; Jos. A. Donohoe, of Donohoe, Kelly & Co.; Falkner, Bell & Co.; Badger & Lindenberger; Taaffe & Co., and J. B. Roberts, Esq. 23v20-3m

MORRIS & WHITE,
Practical Assayers and Metallurgists,
No. 30 and 36 Fremont Street,
SAN FRANCISCO.

Ore of all kinds worked by Pan Amalgamation, Chlorination, or Smelting—guaranteeing to work as close to the Fire-assay as any persons on the Pacific Coast.
☞Gold and Silver Ores and Sulphurets bought.
12v20-qy

CALIFORNIA ASSAY OFFICE,
(Successors to Geo. E. Rogers)
No. 512 CALIFORNIA STREET,
One door west of Montgomery.

H. H. LAWRENCE	Manager.
J. A. MARS	Assayer.

Analysis of Ores, Minerals, Waters, etc. 10v20

G. W. STRONG. W. L. STRONG.
G. W. STRONG & CO.,
Metallurgical Works,
No. 10 Stevenson Street, near First.
Ores worked and Tests made with care. Also, Assays of Gold, Silver, Copper, Lead, Tin, and other Metals.

RODGERS, MEYER & CO.,
COMMISSION MERCHANTS,
ADVANCES MADE
On all kinds of Ores, and particular attention
PAID TO
CONSIGNMENTS OF GOODS.
4v16-3m

W. T. ATWOOD,
PURCHASER OF
COPPER ORES, BARS, MATT, Etc., Etc.,
505 Montgomery street, San Francisco.
The highest market price paid for ores assaying 10 per cent and upwards. 23v17qr

CRUCIBLES! CRUCIBLES!
EUGENE DE SABLA,
COMMISSION MERCHANT,
AND SOLE AGENT FOR
J. H. GAUTIER & CO'S CELEBRATED
American Blacklead Crucibles,
No. 310 DAVIS STREET,
SAN FRANCISCO. 20v20-3m

HAYWARD & COLEMAN
IMPORTERS AND REFINERS
—OF—
Illuminating, Lubricating,
—AND—
PAINT OILS,
CONSISTING OF
KEROSENE, LARD, SPERM, ELEPHANT, POLAR, TANNERS, NEATSFOOT, BOILED AND RAW LINSEED, CASTOR AND CHINA NUT.
—ALSO—
Spirits of Turpentine and Alcohol.

Lamps and Lamp Stock!
An elegant and complete assortment.

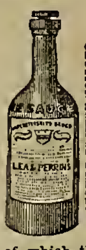
LEA & PERRINS'

CELEBRATED

Worcestershire Sauce.



Caution against Fraud.

Declared by Connoisseurs to be the only good Sauce. The success of this most delicious and unrivalled Condiment having caused certain dealers to apply the name "Worcestershire Sauce" to their own inferior compounds, the public is hereby informed that the only way to secure the genuine is to ask for Lea & Perrins' Sauce, and see that their names are upon the wrapper, labels, stopper and bottle.

Some of the foreign markets having been supplied with a spurious Worcestershire Sauce, upon the wrapper and labels of which the names of Lea and Perrins have been forged, L. and P. give notice that they have furnished their correspondents with power of attorney to take instant proceedings against manufacturers and vendors of such, or any other imitations by which their right may be infringed.

Ask for LEA & PERRINS' Sauce and see name on wrapper, label, bottle and stopper.

Wholesale and for export by the Proprietors, Worcester; Crosse and Blackwell, London, &c., &c., and by Grocers and Oilmen universally. Agents, CROSS & CO., San Francisco. 1v20-1yeow

FARM MILLS.

A superior article for farm use. Operated either by hand or power. Price very low. Send for circular. Manufactured by
22v20-1m LANE BROTHERS, Washington, N. Y.

The Celebrated Studebaker Wagon,

Manufactured by STUDEBAKER BROS. MANUFACTURING CO., South Bend, Indiana. WAGON DEALERS, there are nine reasons why you should buy the above Wagon:

First.—They are made of the best selected INDIANA TIMBER, thoroughly seasoned under cover.

Second.—They are made by experienced mechanics.

Third.—The lightest running and most durable Wagon in the market.

Fourth.—Their Thimble Skeins never break, while all others do.

Fifth.—Most uniform and best proportioned Wagon in the market; any part of one will fit another, while other makes will not

Sixth.—The only Wagon in which the Slope Shoulder Spoke is used; hence they have the best Wheel, which is actually the foundation of the Wagon, and should be carefully examined by persons buying.

Seventh.—They are sold only by responsible parties, and every Wagon is warranted to give entire satisfaction.

Eighth.—Because Teamsters will tell you they are the best Wagons, for all purposes, on the road.

Ninth.—Last, but not least, Studebaker Brothers are practical men, attend to their business personally, and do not entrust it entirely to foremen, as is generally the case in large factories; hence the superiority of their work over all others. Sold by

CALIFORNIA-MADE

FARM WAGONS

FOR SALE.

We still continue to have manufactured in this city and vicinity a large number of these Wagons, made generally for two horses, Light, Medium size, and Heavy, with either Iron Axles or Thimble Skeins—thus ENCOURAGING HOME INDUSTRY, and demonstrating to the satisfaction of every intelligent observer the superiority of California-made Wagons, both as to style, materials and workmanship, over any Wagons sent here for sale, whether made at the State Prison, Jackson (Mich.), or at South Bend (Ind.), or any other Western place, while our prices are very much lower.

Of every description of vehicles now running in California, probably ninety-nine out of every hundred have been made in this State, and their superiority in standing well in this dry climate has been so well established throughout the past twenty years that it would, in the mind of any FAIR DEALER, seem to be an improper reflection upon our many skillful mechanics in this branch of business, to say otherwise.

We are prepared to furnish any reasonable number of these Wagons on short notice.

Catalogues and price lists sent on application.

Persons wishing to purchase, visitors to the city, and all who may feel any interest in the matter, are respectfully invited to CALL, EXAMINE and COMPARE.

The San Francisco Mint.—Coining.

In our previous article we saw how the crude bullion was purified and refined and the gold and silver obtained in a pure condition in bars or ingots. In melting the metal for these bars for coining one-tenth part copper is added, as the coins have a fineness of 900-1000.

Rolling and Drawing.

The first operation which the bars undergo is that of rolling. The rolling machines are massively constructed, for the pressure is very great. There is a dial, marked like the face of a clock, on each roller, and provided with an index. By turning a small crank, the rollers are brought nearer together or further apart, and the distance is indicated by this index. The bars are passed a number of times through this machine, being thereby rolled out into long strips about as thick as the coin is. The pressure is so great that they become too hot to be held in the hand with comfort, and must be annealed at least once, or they will break. The annealing is done by putting a number of strips of gold in a long cylindrical copper box, which is closed tightly with clay, to prevent oxidation of the precious metal. These boxes are put in a furnace, and heated until they are red hot, when they are taken out and cooled in water.

It is impossible to roll exactly true. Here and there the gold is a little harder and not quite so much compressed as in other parts; and coins cut from such places would be heavier than those from others. Hence it is necessary to "draw" the strips, after they have been again annealed and waxed or greased.

The drawing bench is a long table with an endless chain running its length. At one end is a box or framework, on which are fastened two polished steel cylinders, firmly secured, so that they cannot revolve nor bend. By means of a wedge arrangement the distance between them can be altered or regulated with the utmost precision and nicety. One end of a strip, which has been pinched thinner than the rest, is inserted between the cylinders and then between the jaws of a vice fastened to a carriage which runs on the table. Then, by pressing a lever, these jaws are made to grip the strip tightly, while at the same time the carriage is connected with the moving chain, and thereby the strip is drawn through the cylinders and reduced to the proper thickness throughout. When the strip is through, and the strain has ceased, an automatic arrangement causes it to drop, the carriage to be disengaged from the chain and to be returned to the head of the table.

Punching.

From these strips, after they have been cleaned, the planchets, or round pieces, are cut out by means of steel punches, which work in a round hole or matrix, cut in a solid steel plate. A strip is taken and two planchets are cut out and weighed. If these are of the proper weight, or a little heavy, they are allowed to pass, and a half of the strip is punched; then two more planchets tested by weighing, and then the rest punched, if these last are correct. If the test pieces are too light, the strip must be remelted.

To save this remelting, however, to a very great extent, an employé in the S. F. Mint has invented a very simple but effective device. Inside of the punch is fastened a screw, on which is a movable nut. If now the test pieces are too light, the nut is moved downward on the screw until it projects a little below the cutting edges of the punch. Hence, in punching, this nut first strikes the strip and bends it into a concave shape—that is, it depresses the middle of the part to be cut out, and hence more metal remains in the planchet, which has the shape of a segment of a sphere. By properly adjusting the nut, the quantity of metal in the planchet can be materially altered; and hence, if the tests are too light, the next pieces can be made considerably heavier. This simple device effects in the course of a year a very material saving.

Adjusting.

The perforated strips are remelted, but the planchets go to the adjusting room. Here are a number of female operatives, seated at tables, each with a leather apron fastened under her arms, one end of which is tacked to the table, to catch any gold which may fall. Before each one is a scale. The operator takes a double-eagle planchet and weighs it; if too heavy, she files it a little around the edge and re-weighs, and so continues, with wonderful rapidity, until it is just right, when she puts it in a box and takes another. The proper weight of a double eagle is 516 grains, and the smaller gold coins are in proportion. Absolute perfection, however, being impossible, the law allows a variation of half a grain in the double eagle, two of which, therefore, may vary a grain. This is so slight, not two cents in value, that it is deemed sufficiently correct. The weight of a silver dollar used to be 412½ grains, and lesser silver coins in proportion. But an important change was made by Congress in 1853. Previously the ratio of silver to gold was undervalued in the United States, as compared with Europe, and our silver coins were being continually exported. To stop this, the weight of the half dollar was reduced from 206¼ to 192 grains, and the smaller coins proportionately; moreover, silver was made a legal tender only to the amount of $5. The effect was to stop the exportation and to make silver money subsidiary to gold. The weight of the dollar remains unchanged, but this piece is not coined except under special orders, when a premium is charged. One silver dollar (weighing 412½ grains) is thus worth about 7½ per cent. more, intrinsically, than two half dollars (together weighing 384 grains), but as a premium of about 3 per cent. is paid by the mint for silver, the Government gains only some 4 per cent., and this only, if the charges for coinage are large enough to cover the cost.

Only the gold pieces are adjusted in the manner spoken of above. The silver has merely the adjustment of the test planchets, and a greater allowance in weight is made, as it is less valuable.

Milling.

On each coin there is a rim around the edge raised a little higher than the device. This is made to protect the device, etc., and is produced by a most beautiful piece of mechanism called the milling machine, an invention of Mr. Peale, formerly chief coiner at the Philadelphia Mint, and a gentleman to whom are due many other important improvements. The machine can not well be described fully without an illustration. Suffice it to say that there are three vertical tubes, for different sized coins, into which the pieces are dropped. The lowest is caught by a feeder and placed between a revolving steel wheel on one side, and a fixed segment on the other, one end of the latter being nearer the wheel than the other where the coin enters. The planchet is caught in a narrow groove in the wheel and segment, and the space being somewhat less than its diameter, the edge is crowded up a little. The piece makes four revolutions and then reaches the end of the segment, when it falls out. About 120 double eagles can thus be milled in a minute.

The planchet, now called a blank, is then annealed, cleaned with dilute sulphuric acid and hot water, and then dried in a heated revolving drum with sawdust. A number, revolving on a sieve, polish one another.

The Dies—Coining.

The blanks are now ready for coining. A very important piece in this process is the die, and the making of dies is a beautiful process requiring a most skillful workman. No dies are made here, but all are brought from the East. The process is substantially as follows:

A design is first made in wax, and is about six times as large as the coin. From this a brass cast is taken and then reduced on soft steel to the size of the coin by a transfer or reducing lathe, which is itself a most ingenious machine. This die is now hardened by heating and suddenly cooling in water. The relief is raised as on the coin, and this "hub" or "male die" is used merely for making other dies. A cylindrical piece of very soft steel of the proper size is now put in a powerful press and the hub pressed a little into it. The steel is then softened and the hub pressed in further, until the whole impression is clear and distinct. Any defect is rectified with the engraver's tool, the date is put in by hand, and then the steel is hardened and we have a die for coining. About 1,300 dies are said to be made yearly for the different mints. Their cost is about $16 a pair.

The coining presses are massive machines which exert a tremendous pressure. The blanks are put into a vertical tube, whence they are taken, one by one, by a feeder and deposited over the lower die and inside of a steel collar or plate, in which is a hole just large enough to receive the blank, and with fluted sides. The upper die is now forced down on the blank with such power that the device is formed on each side of the coin, whose edge is pressed into the sides of the collar and thereby fluted, this last preventing any filing of the coin by designing persons without detection. As the upper die is withdrawn the lower die also rises to a level with the top of the collar, lifting the coin clear of this. The next blank brought forward by the feeder pushes the formed piece of money away and takes its place. The finished coin drops into a box below. The pressure on a double eagle is about seventy-five tons, yet so rapid are the movements of the complex machine that eighty can be coined in a minute, and smaller pieces, as dimes and half dimes, can be struck off at the rate of 140 per minute.

The coins are weighed and delivered to the Treasurer. In putting them up in boxes care is taken to mix the lighter and the heavier pieces in due proportions—the reader will remember that a small deviation from the standard weight is allowed in each coin—so that each thousand double eagles shall not differ more than three pennyweights from the legal weight. The silver, and sometimes the smaller gold pieces, are counted on an ingenious "counting-board," but the weighing is not omitted.

Amounts Coined, Wastage, Etc.

Space forbids our giving further details with regard to the care taken to collect all the particles of the precious metal, etc., etc. Suffice it to say that the wastage in reality is but a mere fraction of that allowed by law, so nicely is everything arranged. The allowable loss is, we believe, 0.2 per cent. on the whole amount of bullion manipulated; the real loss is often not more than one-twentieth of this.

The following table of the amounts coined at the San Francisco Branch Mint for the quarter ending March 31, 1870, will give an idea of the value of the work done:

January, Double Eagles	$1,620,000
January, Half Dollars	40,000
February, Double Eagles	960,000
February, Half Dollars	25,000
March, Double Eagles	2,100,000
March, Half Dollars	55,000
Total	$4,800,000

The present officers of the Mint here are: General O. H. La Grange, Superintendent; Dr. O. D. Munson, Assayer; C. N. Felton, Treasurer; J. P. Cochran, Melter and Refiner; J. B. Harmstead, Coiner. The efficient management of General La Grange is visible in every department.

A visit to the Mint shows how entirely inadequate to the business is the present building. The new Mint, on the corner of Sixth and Mission streets, is now rapidly arising on its foundations, the corner stone having been laid on the 25th ult. with appropriate ceremonies.

Coinage Reforms.

Congress has been discussing the subject of making several changes with regard to the U. S. Mints, some of which are evidently much needed. We have not the space to particularize these. Reducing the allowed wastage and having the refining done by private parties have been extensively treated of, and on the latter subject and on the mint charges the reader may find a well-written pamphlet by Mr. L. A. Garnett of this city. Mr. J. J. Knox, Deputor Comptroller of the Currency has, at the suggestion of the Secretary of the Treasury, prepared a bill embodying a number of reforms, and we conclude our article with the principal new features of his bill, which are as follows:

The establishment of a mint bureau at the Treasury Department, which shall also have charge of the collection of statistics relative to the precious metals; the consolidation of the office of Superintendent with that of the Treasurer, thus abolishing the latter office and disconnecting the mint entirely from the office of Assistant Treasurer; the repeal of the coinage charge, and authorizing the exchange of unparted for refined bars; a reduction in the amount of wastage and the tolerance (deviation in weight and fineness) in the manufacture of coin; requiring the token coinage to be of one material of uniform value, and to be redeemed under proper regulations, when issued in excess, and the expense of its manufacture to be paid from specific appropriations, and not from the gain arising in its manufacture, as heretofore; an entire change in the manner of issuing the silver (subsidiary) coinage; discontinuing the coinage of the silver dollar; limiting the amount of silver to be used as alloy, so as to make the gold coinage of uniform color; the destruction of the dies not in use, annually; requiring vouchers to pass between the different officers of the mint, in all transfers of bullion and coin; requiring increased bonds from officers of the mint, and authorizing each officer to nominate his subordinate before appointment; and also making it an offense to increase or diminish the weights used in the mint.

Our Agents.

Our Friends can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

☞ Maravilla Cocoa.—*For Breakfast.*—The *Globe* says: "Various importers and manufacturers have attempted to attain a reputation for their prepared Cocoas, but we doubt whether any thorough success has been achieved until Messrs. Taylor Brothers discovered the extraordinary qualities of 'Maravilla' Cocoa. Adapting their perfect system of preparation to this finest of all species of the Theobroma they have produced an article which supersedes every other Cocoa in the market. Entire solubility, a delicate aroma, and a rare concentration of the purest elements of nutrition, distinguish the Maravilla Cocoa above all others. For homœpaths and invalids we could not recommend a more agreeable or valuable beverage." Sold in packets only by all Grocers, of whom also may be had Taylor Brothers Original Homœopathic Cocoa and Soluble Chocolate. Steam Mills—Brick Lane, London. 5v20-1y

To Miners, Millmen and Metallurgists. Kustel's new work on the Concentration of all kinds of Ores, and the Chlorination Process, for Gold-bearing Sulphurets, Arseniurets, and Gold and Silver Ores generally, is the best and most complete work issued. It contains 120 diagrams, illustrating machinery, etc., which alone are of the greatest value. Price, $7.50, postage paid. Published by Dewey & Co., publishers of the Scientific Press, San Francisco.

It is a great thing for elderly persons to have their fading eyesight restored to its youthful perfection. This can be done by Muller, who is recognized as the optician of the Pacific coast. His Brazilian spectacles, properly fitted and adjusted, are superseding all others in use. *

Attention to Mining Companies of Copper and Galena Ores.—A mining engineer and assayer thoroughly acquainted with practical smelting of lead and copper ores, and competent to put up all kinds of furnaces, wishes employment. References given. Please address C. T. MOHRIG, care of Schultz, Fischer & Mohrig, No. 10 Stevenson street, near First, San Francisco. 23v20-1m

Dr. Hartmann, Physician, Oculist and Medical Electrician, cures all diseases of the eye, such as Granulated Eye Lids, Inflammation of the Eye. Opacities of the cornea cured permanently. Also, Paralysis, Rheumatism and all Nervous and Chronic Diseases, and all Female Complaints. 314 Bush street. 25-520.

We call attention to the new portable gas burner—the only one that can be regulated to any size, flame, and burn without smoke or smell. Equal to any gas at one-fourth the cost. P. J. Philips & Co., 650 Market street, have county rights for sale for this valuable invention; also lamps for sale. No one should be without them who wants a good, cheap and safe light. 21v20-4w

Treatment of Rebellious Silver Ores, by Charles H. Aaron—a pamphlet of eight pages of concise reading, of practical value to parties interested in the subject. Printed and sold by Dewey & Co., at this office, for 25 cents, post paid.

Business Fortunes are often made easily, quickly and legitimately by Patent Rights. We advise both sellers and purchasers to patronize reliable agents only. Weister & Co., patent brokers, No. 314 Bush street, San Francisco, are one of the most honest, reliable firms in the United States. *

Brooklyn, Cal., May 31st, 1870.
Messrs. Dewey & Co.—Dear Sirs—Accept my thanks and congratulations for your prompt and efficient measures in securing the approval of my claims. Yours, very truly, A. H. Bangle.

Beware of Tooth Poisons vended under the name of Dentrifices. Adopt and adhere to the only preparation that really preserves the teeth and hardens the gums, fragrant Sozonont. Its effects on decaying teeth are marvellous. *

New Mining Notices.

Land Purchasers' Association.—At a meeting of the Board of Trustees of the Land Purchasers' Association, held June 7th, 1870, the following resolution was adopted by unanimous vote:

Resolved, That an assessment of ten dollars per share, gold coin, be, and the same is hereby levied, upon each and every share of the capital stock of the Land Purchasers' Association now held by subscribers thereto; being for the monthly installment falling due and payable June 1st, 1870. Said assessment is payable on or before the thirtieth day of June, A. D. 1870, to James F. Crosett, Secretary, at the office of the Association, No. 304 Montgomery street, San Francisco.

Any stock upon which said assessment shall remain unpaid on the thirtieth day of June, A. D. 1870, shall be deemed delinquent, and will be advertised for sale at public auction, and unless payment shall be made before will be sold on the thirtieth day of July, A. D. 1870, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

J. F. CROSETT, Secretary.

Office, 304 Montgomery street, San Francisco. jul8

Office of the Placer Gold Mining and Canal Company.—Location of Works: Township No. Six (6), County of Placer, State of California.

Notice is hereby given, that at a meeting of the Trustees of said Company, held on the eleventh day of June, 1870, an assessment (No. 2) of two dollars ($2) per share was levied upon the capital stock of said Company, payable immediately, in United States gold coin, to the Secretary, at the office of the Company, No. 204 Montgomery street, San Francisco, California.

Any stock upon which said assessment shall remain unpaid on Tuesday, the twenty-sixth day of July, 1870, shall be deemed delinquent, and will be duly advertised for sale at public auction, and unless payment shall be made before, will be sold on Tuesday, the sixteenth day of August, 1870, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Trustees.

O. S. HALEY, Secretary.

Office of Company, No. 204 Montgomery street, San Francisco, California. jul8

MANUFACTURERS OF
Diamond-Pointed Drills
AND DRILLING MACHINERY.

For Mining, Quarrying, Shafting, Tunneling, Prospecting, Draining, Grading and Submarine Blasting. Special attention given to Deep Boring for testing the value of Mines. Also to Boring Artesian Wells. Office, 318 California Street, San Francisco. 25v20-3m

A Valuable Book for Inventors and Artisans.—Dewey & Co., publishers of the Scientific Press and Patent Agents, have just issued a neat little volume of over five hundred well executed cuts of the principal mechanical movements known. These useful representations of the various appliances of power are printed side by side with explanatory notes, which makes the subject clear to every reader. Such a book should be in the hands of every mechanic, and form part of every public school library. It is a handy book, and cheap enough for every farm, shop and factory. Sent to any address from the Scientific Press office, postpaid, for $1.—*New Age.*

TARRANT'S SELTZER APERIENT.

Tone and Soothe the Stomach.—Digestion is the primary function of the living machine. If that process is imperfect, every organ falters and fails in its appointed work. The stomach of the dyspeptic is weak and irritable. It requires to be strengthened, refreshed and soothed. Tarrant's Effervescent Seltzer Aperient tones the gastic membrane, and calms the uneasiness which superinduces nausea. The liver of the dyspeptic is inert. The Seltzer Aperient rouses and regulates it. The bowels are constipated or fretful in their action. This excellent saline laxative relieves and controls. In short, it is a true and all-sufficient Elixir for indigestion in all its varied phases, and for all the derangements which proceed from a disordered stomach.

SOLD BY ALL DRUGGISTS.

Hold Your Horses.

The subscriber has the pleasure of announcing to the public a new, novel, cheap, and useful invention, which every person owning a horse needs for every-day use. It is called a "HORSE-HITCHER." You need no longer have your shade trees and fences ruined by hitching to them, nor the street of the city blockaded by posts. With this arrangement any horse may be left in the street or field with perfect safety. Try, and you will hold fast, because you will find him good. Agents wanted everywhere. This invention is one which pays industrious Agents large profits. It is a new thing, never having been offered to the public before. No charge is made for boxing, and no order for less than one dozen is sent, at $10, prepaid or C. O. D., unless a sample, which will be sent on receipt of the retail price, $1.25. One agent sold in three weeks over 500. State, County and Town Rights for sale. Apply to ANTHONY JACKSON, La Crosse, Wis. P. O. Box 409. 25v20-1m

Wood Cutting & Splitting Machine.

This Machine is made of cast iron, constructed without saw, *only with* "STEEL KNIVES," and by removing half a dozen bolts, is easily taken apart or put together in a few minutes; will cut and split more than 40 cords of fire-wood per day, hard or soft wood, as using for stoves and railroad, and requiring but two men to tend it. Can be driven by steam or horse power. The patentee offers the largest inducements to foundrymen and dealers in patents, for the purchase of State and County Rights, and for the manufacture and sale of these Machines in all parts of the country. Secure the right soon. Apply to ANTHONY JACKSON, La Crosse, Wis. P. O. Box 409. 25v20-1m

LESSONS IN ASSAYING,

Determination of Minerals and the use of the Blow-Pipe, to those wishing to gain a knowledge of these branches. Any person may learn to make the ordinary assays in a few lessons. Address me at the Pacific Chemical Works, 215 First street, or Box 1180, Post Office. (25-v20) HENRY G. HANKS.

Greatest Discovery Ever Made.

MR. J. W. MAC, while a resident in New Zealand, was so afflicted with the RHEUMATISM, that for years he was completely crippled and unable to attend to business. The symptoms were of the worst type—knees painful and swollen, with sinews contracted; shoulder, arm and hand rendered useless, and accompanied with continued excruciating pain. While in this state of suffering, he got acquainted with a native of the country, who applied to the parts affected a composition spread on coarse canvas, the properties of which were so wonderful that in a short time all the pain left him, the swelling disappeared, his sinews relieved, and he was able to resume his usual avocations. So effectual has been the remedy, that to this day he has enjoyed perfect health, without the slightest return of his former complaint. Knowing the great blessing such a remedy would be to those afflicted with this painful disease, he with great difficulty and expense obtained the secret of preparing the Plaster; and during the many years MR. MAC has applied these Plasters in New Zealand, Tasmania, New South Wales, and this city, their effect has been marvelous, giving to the most painful and long-standing cases sure and certain relief. The most incredulous will be convinced by referring to these persons: B. W. Owens, 405 Front street; F. B. Alderson, Traveling Agent for Dewey & Co., 414 Clay street; James Flynn, 519 Mission street: Michael Gorman, No. 6 Front street; Mrs. W. S Wright—late of Gilmore House—518 Folsom street, now agent at Virginia City; E. Sbenley, corner Montgomery and Filbert streets; W. M. McLeod, Depository merican Tract Society, 557 Market street, and a host of others, who all bear testimony to the unparalleled healing powers of J. W. MAC'S (rightly termed Magic) Plasters, for the cure of Rheumatism, Gout, Weak Loins, Tender Feet and Neuralgia. J. W. MAC may be consulted at his office, rooms Nos. 34, 35 and 36, 128 Kearny street, San Francisco, between the hours of 9 to 12 A. M., 2 to 4 P. M. and 7 to 9 P. M.

18v20-3m

The Latest, Cheapest, and Most Durable.

CRANDALL'S
PATENT SPRING BED.

This invaluable Spiral Spring Bed combines all the good without any of the bad features of the common spring mattrass. It consists of a framework of springs resting on a bed of stronger springs, thus giving it nearly double the elasticity of any other bed. The springs are self-supporting, each pair being independent of the others, and consequently the tendency to sag or incline toward the middle is avoided. Unlike other spring beds, they require no upholstering, and, of course, afford no harbor for fleas or dust. The medical faculty have pronounced it the best Bed in use. It commends itself to those who have examined and used it. They invariably pronounce Crandall's Patent the best Spring Bed ever offered to the public.

These Beds are on exhibition and for sale at the Cabinet Warerooms of

JOHNSON & BEST,

No. 413 PINE STREET, RUSS BLOCK,

Between Montgomery and Kearny. Also at

639 Market Street, near New Montgomery.

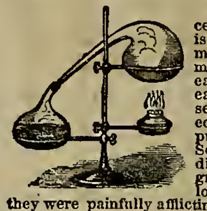
Ayer's Sarsaparilla,

FOR PURIFYING THE BLOOD.



The reputation this excellent medicine enjoys, is derived from its cures, many of which are truly marvellous. Inveterate cases of Scrofulous disease, where the system seemed saturated with corruption, have been purified and cured by it. Scrofulous affections and disorders, which were aggravated by the scrofulous contamination until they were painfully afflicting, have been radically cured in such great numbers in almost every section of the country, that the public scarcely need to be informed of its virtues or uses.

Scrofulous poison is one of the most destructive enemies of our race. Often, this unseen and unfelt tenant of the organism undermines the constitution, and invites the attack of enfeebling or fatal diseases, without exciting a suspicion of its presence. Again, it seems to breed infection throughout the body, and then, on some favorable occasion, rapidly develop into one or other of its hideous forms, either on the surface or among the vitals. In the latter, tubercles may be suddenly deposited in the lungs or heart, or tumors formed in the liver, or it shows its presence by eruptions on the skin, or foul ulcerations on some part of the body. Hence the occasional use of a bottle of this *Sarsaparilla* is advisable, even when no active symptoms of disease appear. Persons afflicted with the following complaints generally find immediate relief, and, at length, cure, by the use of this ***SARSAPARILLA: St. Anthony's Fire, Rose or Erysipelas, Tetter, Salt Rheum, Scald Head, Ringworm, Sore Eyes, Sore Ears,*** and other eruptions or visible forms of ***Scrofulous*** disease. Also in the more concealed forms, as ***Dyspepsia, Dropsy, Heart Disease, Fits, Epilepsy, Neuralgia,*** and the various ***Ulcerous*** affections of the muscular and nervous systems.

Syphilis or ***Venereal*** and ***Mercurial Diseases*** are cured by it, though a long time is required for subduing these obstinate maladies by any medicine. But long continued use of this medicine will cure the complaint. ***Leucorrhœa*** or ***Whites, Uterine Ulcerations,*** and ***Female Diseases,*** are commonly soon relieved and ultimately cured by its purifying and invigorating effect. Minute Directions for each case are found in our Almanac, supplied gratis. ***Rheumatism*** and ***Gout,*** when caused by accumulations of extraneous matters in the blood, yield quickly to it, as also ***Liver Complaints, Torpidity, Congestion*** or ***Inflammation*** of the ***Liver,*** and ***Jaundice,*** when arising, as they often do, from the rankling poisons in the blood. This ***SARSAPARILLA*** is a great restorer for the strength and vigor of the system. Those who are ***Languid*** and ***Listless, Despondent, Sleepless,*** and troubled with ***Nervous Apprehensions*** or ***Fears,*** or any of the affections symptomatic of ***Weakness,*** will find immediate relief and convincing evidence of its restorative power upon trial.

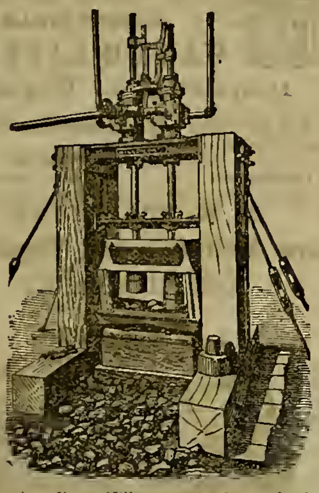
THE WILSON
Patent Steam Stamp Mill.



This extraordinary Mill, now so justly popular in the East, is now offered to the miners of the Pacific Coast. Having been in operation now for about eighteen months, the Company feel confident that the

WILSON STEAM STAMP MILL,

For Durability, Efficiency,

AND ECONOMY OF WORKING,

HAS NO EQUAL.

The Wilson Steam Stamp Mill is the only Steam Mill that has had the severe ordeal of practical working, and proved itself eminently successful. It is now in operation in several of the Eastern States and Territories, and gaining au envious popularity. The whole machine is so simple as to be readily understood by the most ordinary minds. In fact, its simplicity is its durability. The expense of crushing rock or cement with this Mill is less than one-half the expense of any other Stamp Mill, and less than one-half the cost. For further particulars inquire of

A. BICKNELE, Agent,
Nevada City, California,

Or of THE WILSON STEAM STAMP MILL CO., 828 Walnut street, Philadelphia, Pa.

NOTICE.—All persons are hereby warned not to manufacture or use any Steam Stamp Mills that are an infringement on the Wilson Patents, as they will be prosecuted to the utmost rigor of the law.

F. R. WILSON,
20v19-tf Supt. W. P. S. S. M. Co., Philadelphia.

VARNEY'S
PATENT AMALGAMATOR

These Machines Stand Unrivaled.

For rapidly pulverizing and amalgamating ores, they have no equal. No effort has been, or will be, spared to have them constructed in the most perfect manner, and of the great number now in operation, not one has ever required repairs. The constant and increasing demand for them is sufficient evidence of their merits.

They are constructed so as to apply steam directly into the pulp, or with steam bottoms, as desired.

This Amalgamator Operates as Follows:

The pan being filled, the motion of the muller forces the pulp to the center, where it is drawn down through the aperture and between the grinding surfaces. Thence it is thrown to the periphery into the quicksilver. The curved plates again draw it to the center, where it passes down, and to the circumference as before. Thus it is constantly passing in a regular flow between the grinding surfaces and into the quicksilver, until the ore is reduced to an impalpable powder, and the metal amalgamated.

Setlers made on the same principle excel all others.—They bring the pulp so constantly and perfectly in contact with quicksilver, that the particles are rapidly and completely absorbed.

Mill men are invited to examine these pans and setlers for themselves, at the office, 229 Fremont street,
1v1 San Francisco.

TO MILLMEN.

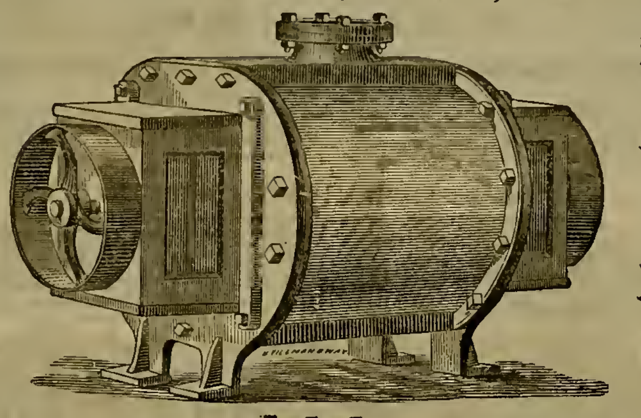
FOR SALE CHEAP.—A 10-stamp mill complete; engine about 35 horse-power; cylinder 12-inch bore and 30 inch stroke; boiler 16 feet long and 48 inch diameter; weight of stamps complete, 650 pounds. The whole is as good as new; has only been running four months. Will sell either engine or battery separate, and deliver it on the railroad at Auburn if required. For particulars apply to W NAGEL, 702 Bush street, San Francisco, or to MOUNTAIN CO., Forest Hill, Placer county. 16v20-3m

ROOT'S PATENT FORCE BLAST ROTARY BLOWER.

MANUFACTURED BY KEEP & BARGION,

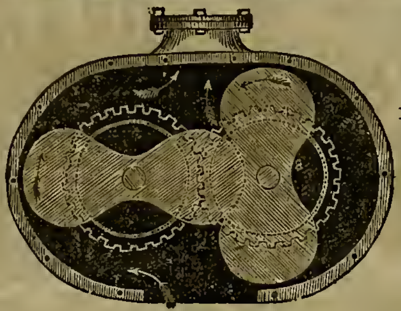
At the Globe Iron Works, Stockton, California.

Awarded the First Premium at the Paris Exposition.



Patented Nov. 1st, 1864; July 24 1866; and Oct. 9, 1866.

ADAPTED FOR **Smelting, Foundry, Mining and Steamships.**



REQUIRES **Fifty Per Cent.** LESS POWER Than any Blower Now in use.

One of these Blowers may be seen on exhibition at W. T. Garratt's Brass Foundry, corner of Mission and Fremont streets. They are also in use at the Almaden Quicksilver Mine; Gridley's Foundry, Gold Hill, Nevada; Ætna Iron Works, San Francisco, and many other places.

CAUTION.—Purchasers will find it to their advantage to apply direct to the Stockton Agency, as certain parties, not authorized to manufacture the Blower, have put in the market machines of inferior construction, which do not answer all the requirements of the genuine article.

Quartz, Saw and Grist Mill Irons, Steam Engines, Horse Powers, High and Low Pressure Steam Engines, Steamboats and Propellers, made at short notice.

A Good Agent

Is wanted, on liberal terms, to travel for the SCIENTIFIC PRESS.

I. O. O. F.

THE NEW AGE,

A WEEKLY JOURNAL OF SIXTEEN PAGES.

The "Official Organ" of the I. O. O. F. on the Pacific Coast.

Is devoted to Odd Fellowship, the ARTS AND SCIENCES and GENERAL LITERATURE; and as a family paper is not surpassed by any journal in the United States. Subscription price per year by mail, $5. Delivered in the city, per month, 50 cents. Office, Odd Fellows' Hall, 327 Montgomery street, San Francisco. 19v19

Sheffield Scientific School

Of Yale College, New Haven, Conn.

This department of Yale College, instituted in 1840, and endowed with the National Land Grant in 1866, furnishes advanced instruction in the various branches of Mathematical, Physical, and Natural Science.

The School is under the direction of the President of the College, a Board of thirteen Professors in differe specialties, and six assistant instructors.

Regular courses of study, leading to the degree of Bachelor of Philosophy, conferred by Yale College, are arranged as follows: 1—CHEMISTRY AND MINERALOGY. 2—CIVIL ENGINEERING. 3—MECHANICAL ENGINEERING. 4—MINING ENGINEERING AND METALLURGY. 5—AGRICULTURE. 6—NATURAL HISTORY AND GEOLOGY, and 7—SELECT COURSE.

Advanced students are also admitted to optional courses, and if already College graduates, are received as candidates for the degree of Doctor of Philosophy.

Tuition, $125 per year of forty weeks.

The Libraries, Museums, Laboratories and Apparatus accessible to students, are varied and extensive.

For copies of the Annual Circular and Report, letters may be addressed to the "Secretary of the Sheffield Scientific School," New Haven, Conn. v16-1y16p

ENGRAVING ON WOOD DESIGNING AND ENGRAVING on wood and for electrotype cuts of every description, done by superior artists at the office of the SCIENTIFIC PRESS. Fine Cuts made for Book and Newspaper Illustrations, and for Fancy Labels for printing in various colors; Monograms, Seals, tc., etc. Promp execution and reasonable prices.

DEWEY & CO.,
No. 414 Clay street, S. F.

WIESTER & CO.,

PATENT BROKERS,

No. 314 Bush Street, San Francisco.

PATENTS BOUGHT AND SOLD ON COMMISSION.

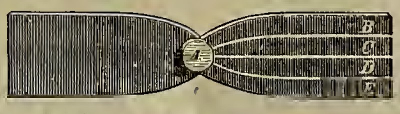
For the benefit of those who live at a distance from the city, we give below a brief description of a few of the valuable Patents which we have in our office. It may be well to state here that no Patent is received by us for negotiation until it is first endorsed by reliable experts, to whom each is subjected for acceptance or rejection. We treat all patents alike, recommending only where true merit is found in the invention.

P. DAVIS' WIRE AND PICKET FENCE.

Patented June 29th, 1869.

Although about two hundred different styles of fences have been invented and patented in the United States within the past ten years, yet this Fence, for GENERAL FARM USE, stands at the head of the list. This is a Virginia invention, and the actual cost of the Fence complete in that State is less than fifty cents per rod. Three men can put up six hundred yards per day. You men who are idle, why hang about the city talking hard times when you can make from five to eight dollars per day building this Fence? We will make a present of ONE FARM RIGHT in each county on the Pacific coast to farmers who will erect one hundred rods of the fence in good style within thirty days after the privilege is granted. We wish to employ several working men to travel in this State and Oregon. Price of territory, and circular with full description of fence, sent on application.

RYAN'S NEW METHOD OF MAKING WHEELS.



To make indestructible iron wheels with little labor and at small cost, is the object of this invention. The hub and spokes are all made out of a single piece of iron. It is first forged down at the ends to the thickness required for the spokes, leaving a hub in the center. The ends are then split into four or more strips each, as shown in the cut above. A represents the hub; B, C, D, E, when spread to their proper position, form the spokes to one-half the wheel. When the other half is split and spread in a similar manner, the spokes are then rounded and shoulders formed on them ready to receive the tire or rim. It is claimed that the great amount of labor and expense heretofore required in making wrought-iron wheels is obviated by this novel mode of construction. There probably never has been a wheel made that is so durable as the Ryan Wheel, and yet the method of construction is so simple that it can be made by any ordinary mechanic in a common blacksmith shop. All territory west of the Rocky Mountains for sale in States or counties. Thomas Ryan, of Scott's Bar, California, is the inventor. Sample wheels, and the iron from which they are made, can be seen at our office, 314 Bush street, San Francisco.

MORTON'S CORK EXTRACTOR.

A GOOD THING. For sale on liberal terms. Illustrated in the SCIENTIFIC PRESS April 2, 1870. Further particulars next week.

Crucibles.

The Patent Plumbago Crucible Co.

Manufacturers of all kinds of

Melting Pots, Portable Furnaces,

CRUCIBLES, and other fire-standing Goods.

Battersea Works, London.

THE MORGAN PATENT CRUCIBLES have uniform quality, never crack, withstand the greatest heat without danger; heats more rapidly than any other; change of temperature has no effect on them; stand on the average forty to fifty pourings.

CERTIFICATES:

United States Branch Mint, San Francisco, Cal., March 12, 1869—Messrs. A. S. Hallidie & Co., Agents Morgan Crucible:—I have carefully tested the Morgan Patent Plumbago Crucibles purchased from you for the U. S. B. Mint, and cheerfully certify to their superiority and economy over all other Crucibles used by and under me. They are fully what you represent them, and I shall continue to use them in preference to any other. J. M. ECKFELDT, Melter and Refiner, U. S. B. Mint.

Eagle Brass Foundry, 206 Fremont street, San Francisco 12th March, 1869—Messrs. A. S. Hallidie & Co., 519 Front street—Gentlemen:—We have used and tested the Morgan Patent Plumbago Crucible, for which you are agents, and pronounce them superior to and cheaper than any Crucible used by us heretofore. GREENBERG & MOORE.

Messrs. A. S. Hallidie & Co.:—We have thoroughly and severely tested in every way the Morgan Patent Plumbago Crucible obtained by us from you, and find them superior to any we have yet tried, although we have used every pot obtainable in this market, we have none equal to the above, and concede your claims for them. We think they will average 45 pourings of brass. GALLAGHER, WEED & CO., California Brass Works, 125 Front street, San Francisco.

Assay Office of H. Harris, Silver City, Nevada, April 24, 1869—Messrs. A. S Hallidie & Co.—Gents.:—I received from you three Crucibles of the Morgan make, which I have used since their arrival, and tested by constant use. Since 1847, when in the New Orleans Mint, I have always preferred the Crucible of Dixon's make over Adus, Gautier, and Taunton, Mass. Yours I find to be not alone of more finished make, but to stand double or treble the work of Dixon's Crucibles. The No. 12—the smallest sent—has stood so far 32 meltings, and is as good and sound as when received. Your Crucibles do not scale off like others; and as they are forty per cent. cheaper, I do not see why they should not be preferred by all assayers on account of durability and cheapness. Yours respectfully, H. HARRIS.

On hand and for sale by the Agents,

A. S. HALLIDIE & CO.,
18v18-9p **519 Front street, San Francisco**

SCIENTIFIC PRESS.
AN ILLUSTRATED JOURNAL OF SCIENTIFIC AND INDUSTRIAL PROGRESS,
Mining, Farming and Mechanic Arts.

BY DEWEY & CO.,
Patent Solicitors.

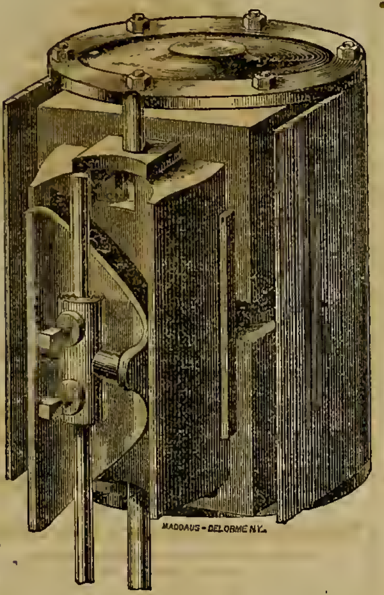
San Francisco, Saturday, June 25, 1870.

VOLUME XX.
Number 26.

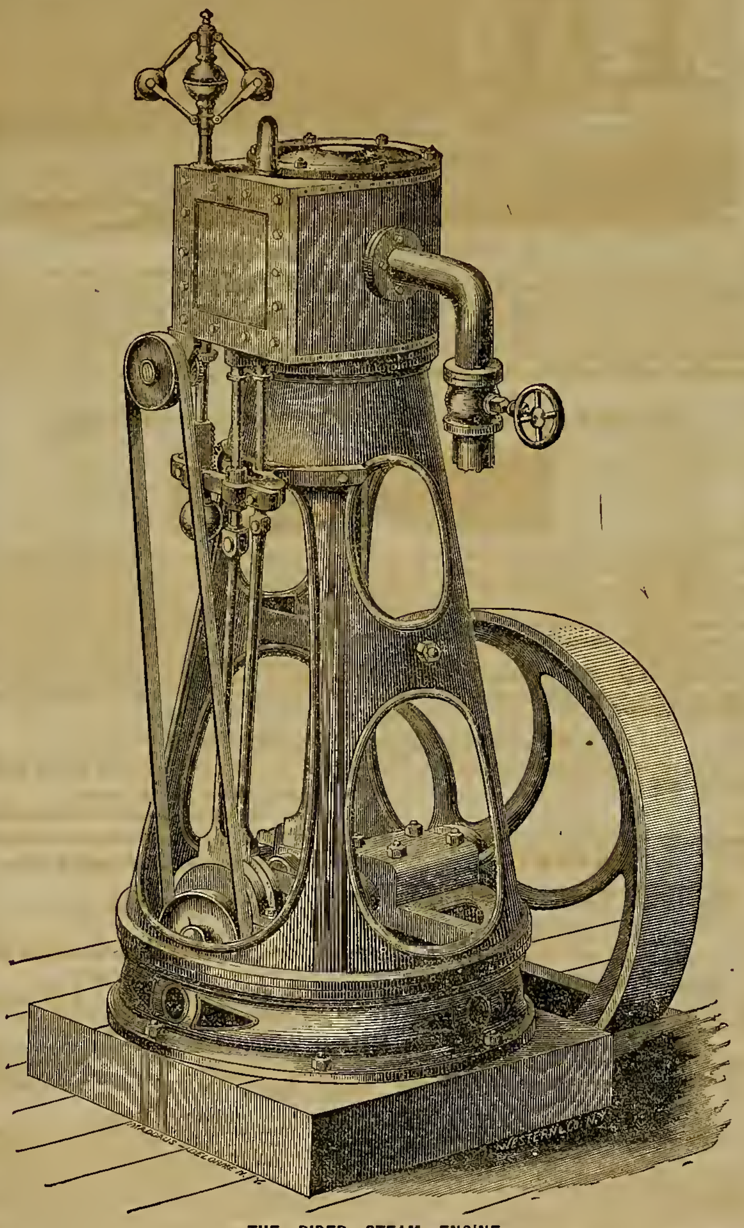
The Rider Steam Engine.

To keep pace with the improvements made on the steam engine alone, requires a large share of attention on the part of those interested in the mechanic arts. Every day we hear of new devices which claim to be worthy of the attention of the public. To speak of such which are praiseworthy, is the part of a paper devoted to the interests of the people, and as such, we have from time to time devoted as large a portion as possible of the PRESS to the remarks on various inventions.

We illustrate to-day an engine which has met with much favor, and which has received many testimonials to its excellence. The Rider engine is one which is well known and extensively used. It has several modifications, but we propose at present to speak merely of the vertical form.



Here one great object has been, to unite with other advantages the economy of room. On a strong and compact conical column is placed the cylinder, and below is the crank-shaft. The amount of floor-room thus occupied is very small, as is evident from an inspection of the first figure. The general effect is certainly very pretty. Besides this point, the attention of the reader may be called to the construction of the variable cut-off, so important a part in economical respects. This is represented in the second figure on an enlarged scale, the valve-chest being removed. There is a single main valve and a single cut-off valve. The former has the outer orifices of its steam-ports made obliquely to its length, as shown in the figure, and its back is hollowed out so that the cut-off valve can play longitudinally in the seat thus formed. The ends of the cut-off valve (which is of the form of part of a cylinder) are shaped so as to correspond with the ports. The two valves are worked by separate eccentrics so that the ports are opened to their full width at the commencement of the stroke. The closing of them is regulated by the governor, which by its rise and fall turns the cut-off valve in its seat. For this purpose the lower part of the governor rod is provided with a toothed rack, which acts on a toothed sector geared with the stem of the cut-off valve.



THE RIDER STEAM ENGINE.

The main valve has three ports. The engraving rather gives the idea that the cut-off valve is of rectangular shape with curved corners. It is, in fact, of the form of a segment of a cylinder. It is obvious, from the cut, that, as it is turned to the right or left in its seat, it will close the ports earlier or later in its longitudinal movement.

This engine is manufactured by Messrs. Handren & Ripley, of the Albany St. Iron Works, corner of Albany and Washington streets, New York, under the patent of Mr. A. K. Rider. The material and workmanship are of the best, and we are willing, from what we hear and know of it, to believe that it is, as claimed, a most effective, durable and economical device. There is a large and growing demand for engines on our coast, and we advise an examination of the one in question.

THE TUOLUMNE RE-UNION at Humbold Park, Oakland, occurred on last Friday. We were unable to be present, although desirous of participating in the festivities, and the pleasant accounts we hear of the very enjoyable occasion makes us all the more regretful that we did not "let everything slide" and go. We return thanks for the ticket sent us.

◆

RAILROAD EXTENSION.—The Western Pacific Railroad Company are to extend the Alameda road from Hayward's to Decotah, and as soon as this is completed, trains to and from San José will pass over it.

Mining and Agriculture.

The Elko *Independent* describes a valley situated about 40 miles northeast from that place, and known as Independence Valley. It is easy of access by two good wagon roads, one from Elko and one from Carlin. The valley proper is nearly thirty miles in length from north to south, and about ten miles wide from east to west, containing first-class farming, meadow and grazing lands, which are watered by hundreds of beautiful mountain streams, filled with jumping speckled trout, and large fat salmon from the far-off Pacific. The valley is bounded on the east by that heavily timbered range of mountains called the East Range, supposed to be non-metalliferous, but containing a world of wealth in the shape of sawing and building timber. Upon the west it is bounded by a range of mountains, the lower portions of which are intersected by numerous gold-bearing quartz veins, which afford excellent placers, where good wages are earned by mining in the most primitive manner. This placer is about ten miles long by two in width, and is well provided with water. A mining district has been established there for some time. A 4-stamp quartz mill has just been erected there by the brothers Bierd, the pioneer locators there, but at last accounts had not been started.

Aside from the gold placers on its western border, and its exceptional size, this valley is but a type of hundreds of others equally valuable, and situated in almost every quarter of the great State of Nevada.

Our mountain lands have hitherto been greatly undervalued as to their agricultural worth. But we are now entering upon a new era. Miners everywhere are beginning to look with favor upon agricultural settlers in their midst, and are willing to accord them all reasonable protection, to the end that they, the miners, may thereby obtain breadstuffs, vegetables and fruit at more reasonable rates than when compelled to transport them long distances over rough and heavy roads. The contemplation of hundreds and thousands of acres of valuable agricultural lands ruined by mining, from which only scanty wages have been obtained and that for a single year, is impressing upon the minds of miners that the single crop of gold so dearly earned, affords no adequate return for the loss of farming lands that, under a different policy, might have endured forever, giving annual wealth to the community, building up permanent homes, and rendering valuable, by cheapening the cost of living, numerous mines that otherwise could never have been worked to a profit. It is for the advantage of the miners, as a body, to protect the interests of agriculture against any unwarrantable waste of mining desolation.

◆

NEW TELEGRAPH COMPANY.—The office of the Atlantic and Pacific Telegraph company was formally opened on Wednesday.

◆

THE fare on the railroad between New York and San Francisco has been reduced to $130.

Communications.

Elko and its Springs.

[Written for the Scientific Press.]

Editors Press:—Elko, Nevada, is on the line of the Central Pacific Railroad, about 606 miles from San Francisco and 275 miles from Ogden, and is situated at an elevation of 5,030 feet above the sea. It was located early in 1869, during the White Pine excitement, and has since been steadily flourishing, until now it has a population of a little more than 1,000 persons. It is the county seat of Elko county, and a court house, costing nearly $2,800, has just been completed; there are good schools now in operation, the railroad has three large depots, a good hotel has been built, at which many westward-bound passengers lay over, and, finally, there are two newspapers printed in the place. One of these, the *Independent*, is very successful under the able management of Messrs. Perkins & Street. I see that the Hon. T. J. Butler, formerly of the Owyhee *Tidal Wave*, is about to publish the Elko *Chronicle*.

About a mile and a half from the city, to the southeast, are some fine warm sulphur springs which are said to possess medicinal properties, and which I visited when in this vicinity. Mr. S. P. Dorsey runs a stage thither from Elko three times a day, and takes one out in buggy time.

The Humboldt Hot Springs.

These are the first which were taken up, this having been done in December, 1868, by Gov. Bigler and Col. T. Henley, of California. In a low basin, some 500 feet in diameter, are two very large springs, one cold and one very hot. The cold spring is about 60 by 35 feet, and 28 feet deep, so that one can enjoy a pleasant swim. Alongside of this, separated by a natural partition not three feet wide, is the hot spring, 100 by 60 feet, and which has been sounded, I am told, to the depth of 200 feet! By letting the hot and cold waters mix in proper proportions, one can have a bath of any desired temperature. The temperature of the hot spring is from 125 to 150 degrees.

Two rooms are fitted up for persons who desire a steam bath. There are boxes or compartments, 3 by 6 feet in dimensions, into which rise the vapors from the hot water, which will steam a man to his satisfaction in a few minutes. It is proposed to build a good hotel containing eight or ten large rooms for the accommodation of visitors, and the old house is to be remodeled and furnished for patients. A doctor will reside here to take charge of the sick.

The Humboldt Sulphur Springs.

About 600 yards off are springs owned by Messrs. Laumeister & Goepper. Here are six fine bathing rooms, furnished expressly for ladies, and others intended for gentlemen. The grounds are being fitted up nicely with summer houses, etc. The springs are smaller than the others, and situated considerably higher. The hot and the cold waters are conveyed through troughs into tanks at the bathing houses. The temperature of the hot spring is 145 degrees.

The composition of the waters here is not known, as no analyses have been made, but it is supposed that they contain soda, lime, iron, saltpetre, and other ingredients. The water is so strongly charged that it is constantly forming a hard coating or incrustation, which in a short time clogs up the boxes.

Springs of Chicken Broth.

There is a small pond, 30 feet long and 20 feet wide, in which eggs can be boiled in a short time, and near by are four small cold springs bubbling up out of the ground. A glass of the hot water was taken and a little salt and pepper added. The mixture tasted like *chicken broth*, so much so that I could not tell the difference, and it makes a delicious drink. The hot water retains its temperature nearly the same throughout the year, but the cold springs often freeze over. It is proposed to erect a hotel to accommodate a hundred guests.

The question as to the causes of the heat is certainly a very interesting one, and one which has not been answered as far as I am aware. The analysis of the water, too, would be of great value, and it is to be hoped that the matter may be investigated soon. The formation here is limestone, and some think that in some way the slacking of the lime by water below the surface of the ground may cause these phenomena.

Artificial Incubation.

At this place I had the pleasure of making the acquaintance of Mr. C. R. Van Allstyn. This gentleman, last April, commenced experimenting on raising chickens and hatching the eggs by means of heat obtained from the spring. He erected some small buildings into which he conducted the hot water. This runs into a tank about twelve feet long, three feet wide and two feet deep, and in this reservoir are placed tin cans holding the eggs packed in straw and cotton. The temperature on the first trial was 120 degrees and he did not succeed. He then reduced this to 90 and 95 degrees, and hatched successfully seven out of the fifteen eggs in each of his eight or ten cans. He is bound to keep on experimenting, and I think he will do well. Miners, you know, all like ham and eggs. It is quite curious to see two or three hundred chickens running about and no large one to be found. [Doesn't this chicken business furnish some hints to the speculative mind on the subject of the broth spring just spoken of?—Eds.] Mr. Van Allstyn intends to put up hot houses and raise flowers, vegetables, etc., if he succeeds with his chickens. He will write you at an early day concerning his operations. [We should be most happy to hear from him. Some remarks on the farming resources will be found in the agricultural department.—Eds.]

Stage Lines.

Elko is the depot for the shipment of freight and passengers for White Pine, Railroad District and other mining camps; also for Cope District and all parts of Idaho Territory. Moreover, those who wish to travel through Oregon can here take Hill Beachey's well-known Railroad Stage Line. The stages leave Elko daily upon the arrival of the western train at 5 P. M.

Hill Beachey is one of the best known, most enterprising and persevering of stage line proprietors. The first to establish stage connections between Idaho and California and Nevada, he has been the only one who has stuck to it, notwithstanding the Indian depredations and the natural obstacles and difficulties. His lines are well patronized and are deservedly popular.

The road from Elko to Silver City is under the able management of Mr. O. R. Johnson, General Superintendent, who has been connected with the company for some years past and who has conducted the business in a very satisfactory manner. The stages have been running from Winnemucca to Silver City, but now the route has been changed to this point, so as to pass through Cope district. At Silver, connection is made with Early's line to Boise city. W. H. M.

Elko, Nevada.

Metallic Soaps.

[Written for the Scientific Press.]

Editors Press:—Some time ago I wrote in your valuable paper concerning Alumina Soap;—that it can be dissolved in oil, and that, possessing a considerable degree of flexibility, it imparts this quality to other substances dissolved in oil, which otherwise would be brittle, and consequently useless for a good many purposes.

Our friend, Mr. C. H. A., a gentleman whom I very highly esteem, wishes me to say a little more about metallic soaps. Mr. A. says that the iron soap is of a rich brown color, and the copper soap of a splendid green tint; but, as he justly remarks, the defect of these, as pigments, is a lack of the property of "covering." This cannot be otherwise expected, since the oily solutions of the metallic soap, leave, after drying, a beautiful *transparent* film of the colors above mentioned. To make them *cover*, they must be mixed with some *insoluble* powder of the same color, and, by so doing, two objects will be gained in using an oil which is already colored by holding in solution a colored metallic soap, instead of the commonly used oil which has no color, namely: it will assist the insoluble pigment in covering, so that a smaller quantity of the same will produce the same effect; and then the work so obtained will be more brilliant, as the glossy coat, after drying, possesses a color in itself. If I were in the manufacturing line, I would try to introduce into public use linseed oil, holding in solution different metallic soaps, to be used in connection with the same kind of oxides in powder form, and I would mix a small quantity of the solution of alumina soap with the above, to prevent its brittleness after drying. One of the many uses of which the metallic soaps are capable, is to render plaster casts impervious to water, and to improve their appearance. The treatment is the following: A soap is prepared by boiling linseed oil with caustic soda solution. The solution of this soap is introduced gradually into a boiling solution of 8 parts of blue vitriol and 2 parts of green vitriol, until completely decomposed. Then a small excess of the vitriol solution is added. The resulting copper and iron soap is well washed and dried. Then prepare a varnish from 4 parts linseed oil and 1 part litharge, and dissolve in 300 parts of this varnish 160 parts of the above metallic soap and 100 parts white bees-wax by applying heat, and melt the mixture for some time, to evaporate the water. This is applied to the plaster casts, previously heated to 80° or 90° C. Dry the same in an oven, and continue the application as long as the plaster still absorbs. Zinc, tin and bismuth soaps produce a white color, and iron soap a reddish brown shade. E. Pique.

Tunneling Bergen Hill, N. J.—It is proposed to drive another tunnel through Bergen Hill, about 30 feet above the level of the present one. This will be about 4,000 feet long. The estimated cost, exclusive of railroad improvements and approaches, is $1,000,000, and the time necessary, three years, if the work is carried on only from the two sides of the hill. By sinking shafts, so as to have several points at which to work, the time requisite for its completion can be shortened, but the cost will be greatly increased. The plan has not been definitely decided upon, but the New York *Herald* says that apparently work will be commenced very soon.

The Peace River Mines seem to have turned out a humbug, and the letters from that region do not speak favorably of mining matters.

Cope District, Nevada.

[Written for the Scientific Press.]

Editors Press:—Leaving Elko for Mountain City at 5:30 P. M., by the Hill Beachey Railroad Stage Line, we ride along due north and arrive at noon of the next day at this well-known mining camp, which is situated near the boundary of Idaho Territory. The road is generally very good, but in places where it is new it is a little rough, owing to the heavy rains and the snow. It will soon be put in good order, however. I was surprised at finding so very fine grazing country all along the route. The hillsides and valleys are covered with as good grass as any ranchman could desire, and water gushes forth from the mountains in abundant quantities everywhere. I saw but few ranches, the small number of which is owing to this being a new road, but I have not the slightest doubt that many will in a short time settle here and raise stock, which can be made a profitable business in this section. The only drawback would be the scarcity of timber; yet I am informed that some seven miles off there is a plenty of this for all necessary purposes.

Mountain City.

Mountain City is situated about 90 miles due north of Elko, on the road to Idaho, on the South Fork of the Owybee river, a small stream which flows in a northerly direction and empties into Snake River. This mountain stream is abundantly stocked with fine fish (trout). The town is about a mile long and has a population of 1,200 inhabitants. There is a post office here; also an express office of Wells, Fargo & Co., a quartz mill of ten stamps and one of two stamps, while many new buildings in the course of erection show that the place is prospering. The city is laid out north and south, and is beautifully situated, although the hills in and around the vicinity are barren in appearance and remind one of Virginia City. The climate is changeable and nearly the same as at the last-mentioned place, but just at present exceedingly fine. The elevation is 5,800 feet.

This district was discovered in May, 1869, by Mr. Cope, of Silver City, Mr. Riley and a few others. These gentlemen were on the way to White Pine, but finding some rich "float" near this place, located a few ledges. They then went to Elko for provisions and there became acquainted with Col. C. S. Drew, who with a few others came hither to prospect. The colonel, who is one of the most energetic and persevering of prospectors, concluded that this was a good place to settle down in, and has erected the 10-stamp mill here. And here let me return thanks to this gentleman and others for the uniform kindness and courtesy shown me during my visit. Miners generally are the most obliging and generous class of mankind;—those of Cope District are the princes of miners in these respects.

The district is about five miles wide and ten long. The first location, made by the Cope party, was on the Pioneer ledge, about half a mile east of Mountain City. The formation is principally slate and granite on the west side of the river, and on the east side granite, resembling that at Austin in many respects, and apparently considerably decomposed in various places.

Cope Mill and Mining Co.

The mill of this company is situated in the city, near the river, and is owned by Col. C. S. Drew, B. Reinhardt and Col. Wingard, of San Francisco. It is built substantially and after the latest pattern, and has ten stamps, four amalgamating pans, two large settlers and an excellent 35-horse power engine (cylinder 12x24 in.), built by Booth & Co., of your city. This mill can crush some twenty tons daily, running during the twenty-four hours. The last month's run was 500 tons. They burn daily about five cords of cottonwood, which is found some seven or eight miles back, and which costs $8 per cord. This is the pioneer mill here and was erected last fall. The two-stamp mill, referred to above, is owned by Messrs. Canty and Allen, but is not running now, having proved too small to be profitable. The owners hope to increase its size, to have five stamps, and then think they can work it. The power is sufficient for eight stamps. They have been in pecuniary difficulties, but their prospects are better now.

There is a great need of more mills here. Nearly all of the miners have ore on the dumps which they cannot get worked, and thus there is an apparent dullness here without any real reason therefor except this scarcity of milling apparatus. A number of companies are shipping their high-grade ores to San Francisco for reduction. The Argenta M. Co. has made special arrangements with the Cope mill for crushing some 1,500 tons of their ore. Some of the miners requested the Argenta Co. to release the mill from this contract for a short time until *they* could get a small quantity crushed, but were informed that no release could be granted for several months, but that the company would loan them money if needed.

Argenta S. M. Co.

The mine of this company is about a quarter of a mile due north of the city and about 200 feet above it. The ledge runs northeast and southwest, with an easterly dip, and crops out boldly from the granite formation. It has been stripped at the surface for a length of some 700 feet. The ledge is from two to twelve feet wide, with well-defined walls, and the rock yields in the mill from $450 to $1,245 per ton for first-class, and about $100, on an average, for second class ore. The superintendent and owner, Mr. T. J. Kiely, very kindly took me through the mine. We went down the incline which extends 140 feet to the tunnel. Some 70 feet from the surface is the first level, running southerly on the ledge about 80 feet, exposing some very good ore, and 70 feet northerly (northeast), where the miners are extracting rich rock. The tunnel below taps the ledge at a distance of 200 feet from its mouth. There are thirty men employed, and the number will be increased as soon as there are proper facilities for reducing the ore. This ore is very coarse-grained quartz, holding native silver, hornsilver, fine sulphurets and "chlorides." I have seen pieces burned in a forge which were completely covered with the pure silver.

Excelsior Mine.

This was located by the Argenta company, May 27, 1869, and is situated but a short distance from the Argenta mine and to the northwest of the city. We entered through the tunnel which strikes the ledge some 60 feet from its mouth. This ledge runs north and south with a dip of 48 degrees to the east. It is from 2 to 6 feet wide and has on each wall a "parting" (as they call it here) of fine soft clay. The ore is rich and easily worked, a sample of 100 pounds in the mill yielding at the rate of $290 per ton. The company has stoped to a height of 15 feet up from the tunnel, where I find the ledge 5½ feet wide. There are upwards of 80 tons of rock on the dump.

Leaving the tunnel, we went up the hill to where the ledge was first struck and where it crops out boldly. The rock contains fine black sulphurets and chlorides and is very rich. The bullion is from .975 to .985 fine and contains 5 per cent. (?) of gold. I understand that Norton & Co. are about to put up a 12-stamp mill near the mine, and not far from the river, and have contracted for 1,000 tons of ore, with the privilege of having 5,000 tons from this (Argenta) company.

Mines on Buckeye Hill.

Buckeye Hill is situated west of the city, across the river, and on it are some fine lodes. The oldest locations were made last May on a ledge called the Buckeye, by the Argenta company and by a party represented by Col. Drew. But little work has yet been done on this ledge, except along the surface.

The Monitor lode, owned by Geo. Curtis and others, is about 5 feet wide, and on it a shaft has been sunk 20 feet. The owners have taken out about 25 tons which will assay $567, and they think will average about $60 per ton by the mill process. [There must be some mistake in these figures.—Eds.] The vein is well-defined and contains black sulphurets.

The Belle of the West, owned by C. H. Massie & Co., is situated some 250 feet above the city and in a northwesterly direction. It has an average width of 40 inches and a dip of 35 degrees. The shaft is 50 feet deep, and there are indications below of a dip of 45 degrees. The company are working with vigor and are taking out very fine rock, which is somewhat decomposed, works well and contains considerable gold.

The Great Eastern, northwest of the Monitor, owned by T. F. Fuller, James Patterson and others, is 2 feet wide, with a dip into the hill of 45 degrees. There are on the dump some 50 tons of ore carrying black sulphurets, chlorides and fine gold.

The Mammoth lode is situated some 400 feet below the last vein, and runs parallel with it. It is 3 to 4 feet wide, and there are some 3 to 6 feet of earth on it which the company is washing off with water from the Placer miners' ditch. Four tons, worked by Capt. Dalls, at Washoe, yielded $456 per ton, and it is thought that the 200 tons on the dump will give over $100 per ton.

Crescent Hill.

A quarter of a mile due west from Buckeye Hill is Crescent Hill, on which is the well-known Crescent ledge. The ledge runs north and south, is 1 to 3 feet wide, with an easterly dip of about 40 degrees. The gouge is of soft clay and decomposed granite and quartz. The rock is easily worked, it not being necessary to blast. Some eight tons sent to Stewart & Co., of San Francisco, yielded $300 to $356 per ton. The mine is well timbered, but only a few men are at work at present stoping. Mr. J. Johnson is the foreman. There is a very large amount of ore, some 200 tons, on the dump, ready for milling, and worth, it is thought, about $90 per ton.

Mountain City Hill.

The famous Mountain City mine, owned by Page, Davis & Co., is situated on this hill about one mile from the city, on the south side of the river. The ledge runs north and south, has well defined walls, and is nearly perpendicular. The country rock here is slate. The work is being done in a systematic manner with a view to the future erection of large hoisting works, etc. The shaft on the vein is about 6x12 feet and 80 feet deep, and is well timbered. We entered through a tunnel—the first level—which strikes the main shaft at a distance of 80 feet and at a depth of 40 feet. On the lode we could see native silver and black sulphurets. Only twelve men are working at present, but 150 to 200 could be employed. There are now 500 to 600 tons of ore on the dump which will average $150 to $200, but there are no milling facilities. The company intends putting up a mill of their own at an early day. The ore is exceedingly rich and has worked as high as $300 and $500 in the mill. Five tons, already sacked, are to be sent to San Francisco. It will yield about $1,000, it is thought.

This and the Argenta are the best mines here, and are being worked on a larger scale than any others. They are certainly wonderfully rich and give appearances of holding out well. Each has its supporters as being the better. They are both very valuable properties. W. H. M.

Montana City, June 10, 1870.

[to be continued.]

Mechanical Progress.

Adcock's Artificial Obsidian.

The *Engineer* for May 6th and 13th describes in full the experiments made some years since by the late Henry Adcock, upon a new product intended for ornamental architecture and other purposes, for which a patent was taken out, although it has never come into general use. He discovered that basalt, when melted, would, if cooled quickly, take the form of obsidian, or volcanic glass; while if the conditions which are necessary to the formation of perfect crystals from aqueous solutions were observed, that is, if time and space and quietude were allowed, the stony structure would be reproduced. The glass aforesaid could be moulded into any form that might be desired for decorative purposes, or, at a certain point in its cooling, could be rolled into sheets which might be used for roofing, for water pipes, for dairy utensils and a hundred other things. It is quite possible that some Yankee who reads the Press will yet hunt up a place where basalt and fuel and fire-clay are plenty and make a good thing of it. The patent has expired. We quote a paragraph or two of Mr. Adcock's own story:

"Into a furnace arranged in a peculiar manner, I put two crucibles, each holding about 14 pounds of basalt, or Rowley-rag. I increased the intensity of the fire, and, after thirty-five minutes had the basalt well melted. I poured the contents of one on the brick floor: it was a brilliant black glass. I allowed the contents of the other to cool slowly, and under the conditions necessary to insure a crystalline structure—that is, I gave it *time*, and *space*, and *quietude*. On opening the crucible the next day I found that that which had been a fused material was reconverted to the stony structure. Indeed, it so closely resembled specimens of the stone from which it had been melted, in color, in hardness, and in texture, that it was somewhat difficult to distinguish between the raw material and the reconverted product. Letters patent were obtained, and works on a sufficiently large scale were erected to test the value of the invention. These were enlarged from time to time until, eventually, large works were erected, orders were procured and executed, and an architect residing at Handsworth built for himself two houses—in one of which he himself lives—in which the window-heads, window-sills, and string-courses, mantlepieces and other decorations were all cast under the patent from the Rowley-rag material. Other decorative pieces were also cast and sold of a similar character:—Seven sets for a terrace of that number of houses at Ashton Park near Birmingham; six sets for a terrace of houses at Wolverhampton; and similar decorations, comprising window-heads, window-sills, and the like, are to be seen as the ornamentations for numerous houses for miles around the former locality of the works. Finally the whole of the columns, window-pieces, doorways, ornamental steps of the Edgbaston Vestry Hall, in the most fashionable district of Birmingham, in the Anglo-Norman style of architecture, are constructed from castings made of this material, and, from its perfect imperishability, must endure for ages. The works, for reasons which it is not necessary to particularize, have been stopped and taken down, and it seems at present probable that they will not be resumed."

Another Boiler-Feeder.—An apparatus recently exhibited at the Polytechnic Association of the American Institute consists of a hollow metallic steam-tight chamber, suspended from one end of a bar upon knife-edge bearings, counterpoised by a weight, and placed at such a height that the plane of the desired water-level in the boiler shall pass nearly through the middle of the chamber. The steam and water spaces of the boiler are respectively connected by pipes with the top and bottom of the chamber. As the water falls in the boiler it also falls in the chamber, and the diminution of weight in the latter causes it to rise, through being over-balanced by the counterpoise. If the water rises above the desired level, a contrary movement takes place. The balance bar is connected with the supply valve by means of an intervening pinion shaft, which engages with an upper or lower sector rack as the level of the water varies.

Larmanjat's Single Rail Tramway.—We have before alluded to this; and now give some particulars from *Annales Industrielles:*

"The locomotive has four wheels; two—the driving wheels—resting on the ordinary surface of the road, whilst the other two—which have grooved peripheries, and which are situated on the center line of the machine—bear upon the central rail. The carriages have also four wheels arranged in a similar manner; but the adjustment of the springs is such that the chief weight rests upon the wheels running on the central rail, the other wheels merely serving to steady the vehicle. The locomotives are of two classes—those of the one weigh 10 tons in working order, and are capable of drawing a load of 50 tons up an incline of 1 in 50 at a speed of six miles per hour; those of the second class weigh 5 tons, and are capable of drawing a load of 35 tons up an incline of 1 in 50 at a speed of ten or eleven miles per hour; or—by changing the speed—hauling the same load up a gradient of 1 in 20. The cylinders are placed close together under the boiler. The boiler has a steam chamber extending along the top of it from end to end. The crank shaft carries a pinion, with spiral teeth, which gears into a corresponding spur wheel fixed on the driving axles. The driving wheels are not fixed rigidly to their axle, but are connected with it by spiral springs, this arrangement being found to facilitate starting, and to give greater ease in working. The leading and trailing wheels are fixed on the center line of the engine, and are each capable of pivoting on a center. Besides this, the pivot of the leading wheel is fitted with an arrangement by which the weight bearing upon it can be modified at will, and this is an important feature in the construction of the engine."

Steam Water Elevator.—The *Railroad Gazette* describes a new arrangement for supplying locomotives with water, which may also be used for raising water to a height for other purposes. Steam from the locomotive boiler is admitted through a hose and pipe into a tank placed in a well alongside the track. This tank is steam-tight, and is filled with water from the well through an induction pipe by atmospheric pressure. The steam forces the water from the tank through a discharge pipe into the tender, while at the same time the water flows through a small pipe from the bottom into an air-chamber at the top of the tank. This pipe is also connected with the steam pipe, with a check-valve opening towards the latter. There is also a check-valve opening towards the air chamber. When steam is shut off at the boiler, the compressed air drives water back from the air-chamber through the steam-pipe into the tank, condensing the steam remaining therein, and producing a vacuum, which causes the tank to re-fill itself at once with water.

Utilizing Tide Power.—Signor Tommasi's plan consists in providing a strong pipe below low tide, extending horizontally inward to the shore, to a point above mean water-mark. At this point is a large reservoir, with which the pipe connects. From the reservoir a communication is formed to an engine, by which the machinery is driven. The rising tide causes the water to flow through the pipe into the reservoir, and, the latter being closed, the rising of the water within it compresses the air. The escape of the air when the tide falls is prevented by valves, so that each inflow forces a quantity of air under pressure into the reservoir, from which it is conducted to the engine cylinder as fast as needed.—*Artisan.*

Oil for Machinery Purposes.—The *Chemical News* says that oils for lubricating purposes may be purified by agitating them with from 4 to 8 per cent. of their weight of a caustic soda lye, sp. gr. 1·2. After twenty-four hours repose, the supernatant oil is decanted from the soapy sediment, thoroughly washed with pure cold water, left to repose, and again decanted and filtered, best through animal charcoal, and through woolen tissue.

Welding Iron to Copper.—The Pennsylvania Railroad Co., after experimenting for two months, upon a new process discovered by Mr. Beazel, which welds copper and all grades of steel and iron together at one heat so that they cannot be separated, even when upset and beaten down under a steam hammer, have purchased the right to use it.

Scientific Progress.

Nutrition and Respiration of the Abyssal Fauna.

We have more than once alluded to the lecture of Dr. Carpenter on "Deep Sea Dredging." We here give briefly his explanation of the manner in which provision is made for the feeding and the breathing of animal life upon the ocean bed.

First, as to nutrition. The higher types feed upon the lower; but the very lowest, the *Protozoa*, how are they nourished? Not by the *Diatoms* from the surface, for their siliceous envelopes are not found at the bottom in sufficient quantity to warrant that supposition. Yet they must have, from some source, organic matter which has been produced from carbonic acid, water, and ammonia through the agency of plants. And this is undoubtedly absorbed by their jelly-like bodies from the assimilable protoplasm, which is universally diffused, in a state of extreme dilution, throughout the ocean waters; and the sources of which are the rivers flowing through miles of vegetation, the fringe of marine weeds upon every shore, the marine meadow in the midst of the Atlantic, covering three millions of square miles, the Gulf Stream, which sweeps around a coast full of organic matter, and the constantly dying and decaying marine animals which are more or less abundant in every part.

As to the respiration. The numerous analyses of *bottom*-water, made by the dredging party, showed that the greater the percentage of carbonic acid therein, the greater the abundance of animal life; and therefore that the stratum of water immediately above the bottom would soon—in the absence of vegetation—become unfit for respiration, unless there was a constant upward diffusion of carbonic acid *to*, and downward diffusion of oxygen *from*, the surface. For this interchange, provision is made in the agitation of the surface by wind; and this is therefore as absolutely necessary for the maintenance of animal life in the ocean depths, as the heaving and falling of our own chests for the aëration of our own blood.

Nature of Blood-Corpuscles.—A paper in *Comptes Rendus*, translated for the *Bowdoin Scientific Review*, details experiments instituted to show that blood-corpuscles are molecular granules of agglutinated microzymas, or microscopic ferments. We give the final paragraph;

"From the facts we conclude: First—The blood-corpuscles are aggregates of microzymas. Second—These can develop into strings of beads, bacteria, etc., like all those which we have previously studied. Third—The microzymas of the blood-corpuscles give birth to cells similar to leucocytes (the white corpuscles), and to other smaller cells more nearly resembling globules. These are then capable of producing cells in various ways. Everything leads us to believe that the blood-corpuscle is as an organism the result of the work of these same microzymas. We are not able to insist to-day upon the consequences which flow out of these researches relative to respiration, which is only a mode of nutrition. The activity of the blood-globules is explained by that of the microzymas which constitute them. In that sense respiration is only a particular case of that class of phenomena which are called *fermentations*."

Sulphuric Acid Saliva.—*Les Mondes*, of March 10th, gives in full the analyses made by Profs. Panceri and de Luca, of the saliva secreted by the *Dolium* and some other gasteropods. Free sulphuric acid was found. This was first noticed by Prof. Troschel in 1853. While he was examining a specimen of this mollusk, it threw out its proboscis, which the Professor seized. There was immediately projected from it a drop of liquid, which, falling upon the marble floor, produced an active effervescence. He collected a portion of it, and satisfied himself that it proceeded from the salivary gland. It was afterwards analyzed by Dr. Bœdeker, of Bonn, who found in it free sulphuric acid.

The Micro-Spectroscope and its Use.

This is a compound microscope with a spectroscopic eye-piece instead of the ordinary one. The construction of this eye-piece is thus described in the *Bowdoin Scientific Review:* "There are two plano-convex lenses, as in the common negative eye-piece, and a dispersing prism. These lenses are, however, placed at a distance asunder, somewhat greater than they would be in an eye-piece of the ordinary construction. The eye lens must be achromatic. In its focus is placed a diaphragm which transversely divides the tube, in whose extremities the lenses are mounted, into two chambers. In the center of the diaphragm is a very small rectangular opening having two of its limiting edges so arranged as to be easily adjusted, by means of screws passing through the walls of the tube and bearing milled heads. The observer is thus enabled to regulate the dimensions of the transverse section of the beam of light admitted to the dispersing prism. The prism may be a simple one of dense glass, in which case the eye of the observer must be placed outside of the axis of the microscope, or it may preferably be compound, consisting of two prisms of dense flint glass and three of crown glass, properly ground and cemented together with Canada balsam. Such a prism gives direct vision and a proper amount of dispersion. Whichever prism is chosen, it is placed in a convenient mounting, just above the achromatic eye lens of the combination."

With this instrument, certain coloring matters used for manufactured wines can be readily distinguished from that of the grape, and the fraud detected. Not only this, but the *age* of the wine can to some extent be determined thereby. Mr. Sorby has experimented extensively upon the subject. We quote a paragraph of his own: "This color of very old wines belong to my group C, and is not changed by adding sulphite of soda to an acid solution; whereas, the characteristic color of very new wine belongs to my group B, and if it could be obtained in a pure state, would probably become very nearly colorless on the addition of the sulphite. This difference between the color of old and new wine has enabled me to contrive a method by means of which I can ascertain the approximate age of a port wine kept in the cask."

The *Review* notes among the uses of this instrument the following: "In determinative mineralogy much aid is obtained by dissolving the substance under examination in a suitable flux, by means of the blow-pipe, and placing the clear bead so obtained (flattened by gentle pressure while still hot), on the stage of the microscope for examination in the usual way. The absorption-bands which then appear, enable us to detect the presence of exceedingly small amounts of the various metallic bases which enter into the composition of the mineral under trial."

Theory of Sleep.—M. Sommer gives the following in Cosmos: "The blood and the tissues store up oxygen to be used as required for the various organic functions. When this provision is no longer sufficient to maintain the vital activity of the organs (the brain, nervous system, muscles, etc.), the body falls into that peculiar state which we call sleep. But respiration, continuing, introduces fresh supplies of oxygen. Of this a small portion, utilized for the production of heat, is given off as carbonic acid, while the remainder accumulates in the blood until sufficient remains to allow the renewal of all the functional activities of the body, and thus awakening results."

Combination of Hydrogen with Sulphur.—Merz and Weith have communicated to the German Chemical Society the observation that the prevalent belief in the incapacity of hydrogen to unite directly with sulphur, is erroneous. When hydrogen is passed over boiling sulphur, sulphuretted hydrogen is produced in abundance. Sulphur also acts on boiling *aniline*, also on *glycerine*, *napthaline*, etc., with formation of HS.—*Chem. Repertory.*

Frog Nerve-Centers.—The movements of the frog from which the brain has been removed, differ from those of the unmutilated animal in this respect, that they are performed mechanically, and with the regularity of a machine. It would also appear, from the experiments of Prof. Goltz, that the nerve-centers for the voice and for the power of maintaining equilibrium reside, not in the brain, but in the spinal cord."
Academy.

Mining Summary.

The following information is gleaned mostly from journals published in the interior, in close proximity to the mines mentioned.

California.

ALPINE COUNTY.

Tarshish.—*Chronicle*, June 11th: The lower tunnel is going ahead as fast as three shifts can push it. It is now in about 600 feet.

The Leviathan.—The smelting furnaces have been placed in position. The mine in the upper tunnel looks fine, and a large amount of very rich ore—from 30 to 45 per cent. copper—has been sacked for shipment. The lower tunnel is in 450 feet.

Exchequer.—*Miner*, 11th: Several tons of the low-grade ore will be put through the M. C. mill next week.

M. C. M. Co.—Letters from the Eastern agent of his Co. give assurance that the management here will soon be in funds to push the explorations and to finish up the mill.

The lower tunnel of the Schenectady is in 600 feet, and it is thought will reach the deposit in 200 more.

CALAVERAS COUNTY.

Incline—*Chronicle*, 18th: The machinery for the tunnel is completed and will be set in motion soon.

Burr.—The Burr mill, at Railroad Flat, is now in active operation. Miners are now hauling their rock to be crushed from every direction.

Railroad Flat.—Cor. of same: Mining prospects continue flattering. A. F. Burr has his mill running. The ore now being worked is principally from the Chapman mine. It will probably not yield as well as much of the rock from this mine. Owing to the insufficiency of machinery, they are unable to progress with their shaft. The greatest depth yet reached is 100 feet, at that point they have a large lead of excellent ore. Rock from the Wet Gulch mine is being crushed, which bids fair. Lewis Bros. & Co. are delivering ore at the mill. A strong force of prospectors are hunting for new lodes. Some meet with success.

KERN COUNTY:

A Los Angeles telegram of 15th says: A new mine has been found on lower Kern river, near Bakersfield, by a Mexican sheep herder, which, it is claimed, shows a better developed ledge than any of the once famous ledges of Kern county, and is said to be as rich as any yet opened in the lower country. The ledge is traced 380 feet, and specimens are exceedingly rich in free gold. The discovery causes some excitement in that vicinity.

NEVADA COUNTY.

Good.—Grass Valley *Union*, June 15th: Perrine mill has just cleaned up after crushing 160 loads of rock. The result was $6,445.

Items.—Same of 16th: The Badger mine is being pumped out rapidly. The water in the shaft has been decreased eighty feet. By the last of the week the mine will be ready for taking out rock.... The Bowery mine is being worked with every prospect of success. It will be remembered that the Bowery has paid $83 per ton from the surface down....The Seven-Thirty mine has started up....The Town Talk gravel mine has made a clean-up. A twelve days' run gives $1,200 with an expense of $600. The cement is crushed by an eight-stamp mill, run by water. The company will soon add eight stamps.... Ben McCauley's mill has been crushing float rock from Alta slide with good results. Eighteen tons gave $200....The Greenhorn is taking out splendid rock.

Green Mountain.—Same of 19th: This company own claims on Greenhorn ledge. The claim is on a ledge three-quarters of a mile south of the Empire mill, on Houston mill. The Co. consists of Truan, Sims and others, and they own now by purchase of Rush & Laton. A recent crushing of 28 loads at the Gold Hill mill gave $3,394. The Co. have on the dump 60 tons of rock, and in sight 500 tons.

Kate Hayes Flat.—*Transcript*, June 15th: A gentleman from French Corral informs us that the cement mills are all paying handsomely. On Friday a blast of two hundred kegs of powder was set off in the claims of the Kansas Co., which did splendid execution.

Star.—Same of 15th: The company are taking out the wooden stems and the battery, and replacing with iron stems and a new battery. These improvements will be completed in two or three weeks. There is now four hundred tons of rock at the mill.

Manzanita.—Same of 19th: These claims, owned by Marselus & Maltman, are in better condition for working than at any former period, and the ground is improving in richness. They employ thirty men.

Meadow Lake.—In a couple of months a hundred men will be employed in opening mines. Meadow Lake has been regarded as played out, but those who have been there the longest know that there are rich ledges.

Washing at Washington.—*Gazette*, 14th: The claims of Grissel, Eagge & Co. are being opened in the deep channel on the bar, opposite Washington....Ershhack & Co. are driving ahead in their claims by the bridge, and have prospects for a good clean-up.....S. Potis is prospecting for gravel mines near the old Tecumseh mill, six miles above Washington, on the Yuba. ....White & Co. are developing their new quartz mine near the mouth of Big Cañon creek, and taking out some splendid ore.

New Diggings.—Same of 18th: Henefauth & Co. are opening new gravel claims north of Henefauth's. They have been taking out five dollars a day to the hand by sluicing, and will soon have their ground ready for hydraulicing.

Columbia Hill.—Mining for this season is partially suspended for want of water, but the diggings will last fifty years with 3,000 inches of water to work them day and night. We are informed there is one mile square of gravel, from fifty to two hundred feet in depth, that will pay for working.

Eureka Mine.—Grass Valley *Union*, June 21st: The mill had a run of eleven and one-half days, up to Saturday night. The result was a little over $25,000.

PLACER COUNTY.

Ophir.—Cor. of *Stars and Stripes*, 16th: Shinley & Co. had 12 tons of rock crushed at the Empire mill, which returned 10¾ ounces. Oliver & Co. milled nine tons, which averaged $8 per ton. William Goldsberry had 12 tons crushed, from which he received 17¼ ounces. Staple & Choate worked 21 tons from the Hathaway ledge, which realized 35 ounces of amalgam. The St. Patrick is still yielding handsomely. J. McLaughlin, the discoverer of the St. Patrick, is reopening the Doeg ledge. Bryan & Co. have purchased the Little Doeg ledge.

Rattlesnake.—Cor. of same: Jack Duncan, last week, from the proceeds of one day's work, procured enough clothing to last him ten years. While at Newcastle, a day or two since, a Chinaman offered for sale a piece of gold worth $200. I am satisfied that it came from the vicinity of Auburn.

SAN DIEGO COUNTY.

Julian City.—Cor. of *Union*, 16th: A more hopeful feeling exists. The miners are confident that they will checkmate the land-grabbers, and the Cuyamaca scare is subsiding. Gregory Yale, in a speech on Friday, gave a general history of land grants in California, and told the miners not to stop work on account of this one. Mr. Bickers has sold his interest in the Washington to J. T. Gower for $5,000. The Gilman ledge grows wider and the rock richer. They are down 41 feet. The Owens ledge shows three feet in width and very rich ore. The Good Hope is pushing down fast and shows fine ore. In fact, all the mines look well. The McMechan quartz mill—two stamps—will start up in a few days.

SISKIYOU COUNTY.

The Norfolk.—Yreka *Union*, June 17th: Quartz of marvelous richness is being taken out. The ledge is two feet thick. Two men get out three tons a day. The Cottonwood quartz mill will be ready to commence on Norfolk rock on Monday next.

Good Pay.—The Sam Richardson and Bill Smith claim at Cottonwood, has been hydrauliced off, and is now being washed up. For three days' washing last week, they got 28 ounces. There is enough ground sluiced off to keep them washing all summer.

A Good Pan.—Brady & Smith, who have been at work a year on a drain race, got in on Tuesday. They dug up a single pan of dirt, taken from the very spot where they left off work a year ago, and on washing it out had $57.75.

SIERRA COUNTY.

Sold.—*Messenger*, 18th: A controlling interest in the Reis quartz mine, at Sierra Buttes, has been sold to an English Co. at at a price based on $750,000 as the aggregate value of the property.

TUOLUMNE COUNTY.

Chinese Camp.—Sonora *Democrat*, 18th: McFarland, a veteran miner, is about working off dirt on Chinese Hill. The dirt is to be let down in cars and washed on the Salvada Camp side.

Confidence.—The mine in eight days turns out $7,200

YUBA COUNTY.

Sucker Flat.—Marysville telegram, 15th: Mining at Sucker Flat is being vigorously prosecuted, and work is abundant. The suit of W. H. Kender and W. W. Huey *vs* The Poctaluo Gold Mining and Water Co. and James O'Brien, was compromised to-day by entry of judgment, by agreement, awarding plaintiffs the east two-fifths and defendants the west two-fifths of the mine.

Brown's Valley.—*Appeal*, 21st: The Dexter Mining Co. having leased the Donnebroge mill, have about finished the crushing of 200 tons of rock, and the prospects are favorable.

Arizona.

Big Bug.—Prescott *Miner*, June 4th: The news continues good. Tuesday last, a clean-up was made at the mill, after a run of eight days, with ten stamps, and the amount of gold exceeded twelve hundred dollars. The mine is in good condition, and there is rock enough out to keep the mill running several months.

Walnut Grove.—C. G. Genung recently assisted Fred Henry to work two tons of ore, in Mr. Cullumber's arastra: They got $190, and think they lost enough gold to bring the yield per ton up to $100.

Walker's.—The men in the Accidental tunnel have struck rich ore. Shelton is working one from the Vernon. He expects to clean-up soon. The Eureka mill is idle. The parties who have been running it have, as yet, been unable to buy or lease it.

Martinez.—The new district near camp Date Creek, midway between Prescott and the Colorado river, bids fair to eclipse all other districts in the Territory. Yesterday, Sheriff Taylor presented us with a piece of ore from the Mayflower. This weighs several pounds, and shows upon its surface more than 500 particles of gold. The piece was taken from the mine at a depth of 15 feet. Robert Barton and Mr. Stanton, mining experts, had visited the Martinez mines, and started for San Francisco, to procure a mill.

Wickenburg.—Vulture Co's mill is running. Thos. Graves worked a pound of ore from the White Picacho mine, and got two dollars.

British Columbia.

The Victoria correspondent of the *Bulletin* gives mining news, which may be condensed thus: Peace River is worthless. Things at William creek are gloomy. Lightning creek is good. That is to say, as to the last item, one company, which has bottomed the deep channel, gets dividends at the rate of $1,300 per week.

Colorado.

Items.—Central City *Herald*, June 15th: The Gunnell Central Co. start up to-morrow....The Montana Mill, rejuvenated, starts up next week....A. Cameron employs 35 hands in gulch mining, two miles below Black Hawk....This morning we saw a mass of gold weighing 47 ounces 4 dwt., which came from the Lexington mill. It was the product of nine cords of Roderic Dhu ore. The crevice in the Roderic Dhu is four to five feet wide, and the whole pays.

South Boulder.—Rollins' large mill started up this morning. Ore plenty to keep it going all summer....Hollister's (Eagle Co.) mill, 50 stamps, starts this week....In Wide Awake, a stamp mill will be started Monday, on ore from Dr. Brook's lode.

Seaton Lode.—Thirty-seven miners are at work on five different claims, and from most of the shafts a respectable quantity of rich ore is being obtained. That belonging to Capt. Dean, and what is known as the old Womach & Seaton claims, are yielding the principal part. Capt. Dean's shaft is 60 feet deep. On the Womach & Seaton, Mr. Topping is drifting at a depth of 160 feet on a fine vein. Specimens of the ore assayed 300 ounces per ton.

Georgetown Items.—The Brown Co. at their last run, took out a button valued at $5,400 from 18 tons of ore....The Caledonia lode has been sunk 100 feet and has a fine vein of first-class ore....The Clark Co., on the east end of the Terrible, have stopped work, awaiting the return of their agent from England. The west end of the lode is being worked by the English Co.....The Caskill lode, eastern extension of the Terrible, is showing a body of ore a foot in width, which will assay $200 per ton....Stewart has nearly completed work on his new mill.....The Baltimore tunnel has crossed a large lode upon which they propose drifting....Snyder's mill, on the creek below the Snow Drift, is framed and raised....Work is resumed on the Equator.

Items.—*Register*: Bobtail keeps 40 stamps busy....Charles Foreman, on the Smith lode, in Chase Gulch, is raising six-ounce ore....Stevens & Valentine are working the Stub Tail on Gunnell Hill, with good results. Two men are raising from a quarter to half a cord of seven-ounce mill ore per day....The Irish Flag lode in Nevada is producing mill ore, that yields nine to thirteen ounces per cord....The old French lode is waking up....Daniel McGonigal & Co., on the Jones lode, are stoping in No. 3 west and taking out fine mill ore. Two and one-fourth cords yielded thirty-five ounces of gold....The Rochdale mill is busy day and night.... Moss, Morris & Lodford, below Walker's mill, have their shaft sunk to bed-rock, and they took out $90 from the bottom....All the old stamp mills in Nevada are being fitted up anew. Lewis & Tabor are running on California ore. The New Bedford is thoroughly re-built. The Briggs is arranged with a double issue.

Items.—Georgetown *Miner*, 9th: The gulch miners at Idaho are doing finely. They have plenty of water....The Syracuse mill is doing well....On the Edgar lode, the vein shows two feet of $400 ore ....The Whale mill will start about 4th of July....Blazing Star has abundance of rich ore....Chloride lode, Spanish Bar district, is being worked by John Baker. Three feet of the five-foot crevice is pay ore which will average $100 per ton.... Two bars silver from Terrible ore, each over 1,000 ounces, have been shipped since last report....Machinery of 30 tons capacity is now on the way from New York for the St. Lawrence Co.

Idaho.

Snake River Mines.—Corinne *Reporter*, June 17th: Matt Taylor brought in a lot of dust from the Snake River diggings yesterday. There are, perhaps, a thousand men now mining along that river, 150 miles from here. At a point eight miles beyond the Boise stage station, four men took out of an elbow in the bank 50 feet above the water, with two rockers, $600 in five days—at the rate of two ounces a day to the man. Men who have gone from here with nothing but pick and pan are coming back occasionally with the dust to purchase rockers, tools, provisions, etc.

Golden Chariot.—*Avalanche*, 18th: Rock of very rich character is being taken from the fifth level. In the fourth level, for 30 feet south of the shaft, there is a good paying vein from four to five feet in width. A substantial tramway for running out the waste rock has just been completed. It is 150 feet in length, affording a dump of over 100 feet. There are 60 men at work.

Good Move.—The Upper Sinker mill will be moved to a point near the Oro Fino, Ida Elmore, Golden Chariot, Peck & Porter, Mahogany and other mines, and ten stamps added.

Peck & Porter.—Work has commenced. A contract has been let to sink the main shaft 80 feet deeper for $25 per foot. A splendid set of steam hoisting works have been ordered from San Francisco.

Nevada.

COPE DISTRICT.

Ore.—Elko *Independent*, 18th: About 10,000 pounds of ore from Cope arrived yesterday for shipment to San Francisco.

Gold Dust.—P. M. Eder & Co. bought eighty ounces of gold from Chinamen on Monday. The Celestials mined in Independence Valley, forty-five miles north of this city, and brought in from $180 to $277 each.

Toano.—Cor. of Elko *Chronicle*, 19th: From Bald Eagle claim, Lucine district, within eight feet of the surface, they are taking out almost pure copper. The district generally is looking well, is well located, having abundance of wood and water. Teams are arriving daily with quartz from Southeast Nevada, some of which, I am told, are worth $1,400 per ton in San Francisco.

Bruno City.—Cor. of same: The Bruno ledge, Cross & Co., is promising. The Miner's Delight is one of the leading ledges, owned by Savage, McMillan & Co. The Miner's Rest and Mountain King are base metal ledges, bearing first-class smelting ore. The Mountain King is bonded to Oppenheimer & Co. until the 15th of July, at $10 per foot. The Big Giant, Laweou & Co., is a well-defined fissure vein, and shows native silver. The Primrose shows one of the best prospects in camp. Work is prosecuted by Wright & Hafey. The Enterprise, Steele & Co., is being prospected. The Mina d'Alta, Moulder & Co., is bonded. The Mountain Queen shows favorable indications.

The placer mines are of considerable extent. If properly worked, fifteen or twenty dollars per day to the hand could be realized.

HUMBOLDT.

Items.—*Register*, 18th: Mr. Sanborn has made a new discovery north of the Alpha. The ledge crops out bodily, ore rich with native and horn silver. The Alpha works day and night, raising and shipping ore. At Humboldt City a ledge was discovered a few days ago right in the street, which, from appearances, is as rich as any in the district. The boys are still at work in Florida cañon. Omega looks well, shaft down 25 feet. Hon. George A. Carmony, in Butte cañon, Echo district, has struck a three-foot ledge of solid ore, 160 feet below the surface.

Galena.—Robt. McBeth recently struck a large and very rich body of ore on the Butte ledge, and with the Butte Co. is sinking a joint shaft. The Buona Vista Co. shipped twenty tons of assorted ore to the Reno mills for reduction. Bruce & Co's smelting furnace is completed.

Central.—There have been many locations, but little work done on any, except the Arnold and Railroad. The Arnold, in which a shaft has been sunk 100 feet, is a large well-defined vein, and the ore yields $75 to $100 per ton. Muller & Arnold have erected a small mill, which is making the mine pay the expense of developing, and a handsome profit beside. The Railroad, owned by Frank Clark, is a larger ledge, but the ore is lower—$40 to $60.

Battle Mountain.—At a miners' meeton the 6th inst., the laws of the district were revised, making the yearly removal of 10 cubic feet of solid rock, or 50 of earth or loose rock, necessary for the holding of each claim of 200 feet.

Rich Discovery.—Elko *Independent*, 15th: A ledge has been struck this week in Railroad district, which is said to surpass all previous discoveries. Assays of the rock reach $5,000 per ton. The ledge is near Padelford's, at Pine mountain, four miles from the present settlement.

REESE RIVER.

Mineral Hill.—Elko *Chronicle*, 19th: Joe Woodworth informs us the foundation for Huber & Co's mill is down, and the timbers for the frame are being made ready. They are also burning brick and lime for the Stedefeldt furnace, which will be in operation in a short time.

WASHOE.

Sacramento & Meredith.—Gold Hill *News*, June 18th: Owing to difficulty in obtaining water, the new mill has not been able to run up to its full capacity. The first clean-up was made yesterday. It was only from one battery, but was satisfactory.

Hale & Norcross.—Daily yield, 250 tons, principally from the seventh level. The ore breasts at the car-track floor and two floors above look splendidly. The cross-cut, 150 feet north, shows nearly fifty feet width of ore. Receipts for May, $164,830.

Yellow Jacket.—Daily yield, 400 tons. About 150 tons of this is low-grade from the upper workings.

Chollar-Potosi.—Daily yield, 180 tons, assaying $52 on the average. The Belvidere section shows a large amount of good ore in raising toward the surface.

Ophir.—Owing to the breakage of the pump the water has risen 200 feet in the new shaft. Repairs will be completed by the middle of next week.

Imperial-Empire.—Nothing new except that the winze from the 1,100-foot level shows little or no ore at the bottom. It will intersect with the drift at the 1,200 foot level shortly.

Daney.—The first ore produced this season has milled on the average $15 per ton. The mine is looking favorable, and considerable ore is being produced daily.

Sierra Nevada.—Both mill and mine running at the same steady rate. The east surface deposit still constitutes the main ore resource.

Crown Point.—Daily yield, 50 tons, low-grade ore, from the upper levels.

Belcher.—The ore seam, 262-foot level, improves. Prospecting at the 730-foot level develops favorable indications. The daily yield of the mine is 50 tons.

Hope.—Both mills are running, the yield of the mine being from 30 to 35 tons of $20 ore daily. About 16 tons per day of $12 ore are also being extracted, supplying the Atlantic mill.

Kentuck.—Yielding daily 30 tons of fair ore, supplying the Pioneer mill. This comes principally from above the 400-foot level.

Cole.—Within the last week or two considerable surface ore has been taken out, which pays well for milling.

Gould & Curry.—Daily yield, 80 tons, f o n the old mine, average assays being $51.

Overman.—Upper levels yielding ore of improved quality. Receipts for May, $51,000.

Caledonia.—Daily yield, 40 tons, from the 200-foot level. The mine is looking well, with plenty of ore in sight.

Virginia Consolidated.—*Enterprise*, 19th: This mine is being worked with some show of profit to the company through the old Sides tunnel. A body of ore three to four feet in width, of good quality, has been struck at various points above the level of the tunnel.

WHITE PINE.

Review.—*News:* A large number of prospecting shafts are being sunk on the west side of Treasure City. As the base range commences on this ground, and many of the most valuable mines of mixed ores in the district are here, the labor will doubtless be amply repaid. The explorations are conducted principally by poor miners, who hire out occasionally to pay expenses. There is an unstamped deed in the Recorder's office transferring certain mines to an Eastern company. The amount stated in the deed is $500,000. The shipment of silver bars, from Wells, Fargo & Co. for the week ending 13th, amounted to an aggregate of $43,340.84—$21,901.86 to San Francisco, and $21,438.98 to New York.

Items.—Original Hidden Treasure never looked better. The decline in quotations is a "bearing" movement. The ore mills its usual average....Anchor Consolidated consists of the James Emma, Anchor and Treasure City, comprising in all 2,000 feet. The location is about the center of Treasure Hill. In driving the tunnel they ran through 110 feet of solid quartz assaying from $10 up to $150 per ton. In the center of this immense body of ore is a shaft of 30 feet in depth, carrying ore all the way, of the same quality as that in the tunnel....Stanford mill is steadily running on ore from the South Aurora....Six men are at work on the Pennsylvania. Body of ore six feet wide....Silver Vault tunnel now in 180 feet; the last 10 feet through vein matter....Elko vein (base) averages five feet in width. Nine tons daily of rich ore coming out....Silver Wave have struck good ore in their new shaft....Walsh furnace had an eight hours' run, when the foundation gave way, owing to have been laid on frozen ground. It will be repaired as soon as possible. Twenty-one bars were moulded during the run....The Big Smoky mill is running night and day....The Weiland furnace is running on ores from the Elko mine....The Rathburn furnace will fire up in a few days....A rich strike of chloride in the Conover mine, on Babylon hill. Fifty pounds assayed $3,000 to $4,000 to the ton. ....Fifty tons Bromide Tunnel ore worked $40 per ton at Moyle's mill.

Outside Districts.—Some three weeks since, Judge Goodwin, who is running the Wilson furnace at Eureka, on ore from the Jackson mine, bonded the mine for $5,000, and in less than 20 days' run paid the purchase price from the bullion extracted from the ore. The Germania, gold-bearing mine, at Pinto, has five tons of selected ore on the dump. Assays have gone from $1,500 to $12,000. Assays from the Champion run from $400 to $769.80. The poorest ore from the Mountain Chief, on Silverado hill, assays $138.21. James McNevin has a mine in Piuto called the Maryland. The ledge is 30 feet wide, and a sample of a 2-foot stratum assays $1,360.60 to the ton. Miners' meeting in Pinto, on June 1st, made two days' work necessary to hold each 200 feet for one year.

Montana.

Radersburg.—Helena *Gazette*, June 13th: Matters are looking well. A great number of companies on the placer mines are doing well. The quartz is promising. Sample's 12-stamp mill commenced to crush on rock from the Robert E. Lee; Keating's 15-stamp mill will start up this week. The Sample will make a test run on the "Ironclad." There are seven companies working on the Ironclad lode. Nave's arrastra cleaned up $184 from five tons of rock on the Leviathan lode.

Gold Shipments.—Gold dust is coming in freely. S. H. Bohm shipped, on Monday, a gold brick weighing 723 ounces. Yesterday he shipped one, of the coin value of $7,000, and to-day he casts another. All the buyers get more than last year at this time.

Basin Gulch.—Cor. of same: Jim. Halford owns two claims, or bars, a quarter of a mile apart, and is working thirty men on three eight-hour shifts; has plenty of water, and is moving earth and gravel through his two long flumes at a great rate. Mr. Halford is of opinion that Basin Creek will produce $1,000,000 this season.

French Gulch.—*New North-West*, June 10th: A Mexican company are working six men; their last clean-up, after a five days' run, was 59 ounces. Noonan & Co. are working four men, and their last clean-up of a week's run was $980. Claims average from $17 to $18 per day to the hand. The prospects are good for an abundance of water the whole season.

German Gulch.—Most of the companies expect to clean up next week. There is 700 inches of water in the gulch, and all the claims are working ground-sluices. The last snow storm retarded work ten days. Dr. Beel, Gardner and Moore, and McCleery Bros., are each running two hydraulic pipes. There are fourteen companies working night and day. The California Co. is the largest in the gulch, and is working two shifts of five men each. Wages are $5 per day. There are good prospects of water for the entire season.

Silver Bow.—Burton & Herman cleaned up $4,800 from twelve days. Bernard's and all other ditches are full. There are few idle men, but would not advise any more to come, as pilgrims are coming in, and many returning from Cedar. Moran & Russel's claims are paying from $12 to $25. Rocker is as lively as Silver Bow. The diggings here are not coming quite up to expectations. The majority are paying but $7 to $9—others not that, but the average is good.

Pike's Peak.—Cor. of same: The yield on Pilgrim Bar has surpassed all expectations. There are ten claims, yielding from $1,000 to $2,800 each per week. I estimate 3 at $2,800 each; 1 at $2,500; 2 at $2,000 per week—total, $17,600 per week. Six more claims are being opened. Water sells at 25 cents per inch for 24 hours. Wages are $5, $5.50 and $6 per day.

Cedar.—Cor. of same: Everything dull on account of high water. Will be best camps in Montana by middle of August.

Blackfoot.—The Chinese have made purchases of mining ground on the bar below town. It is said they have bought two-thirds of the bar, paying from $500 to $3,800 per claim. Some thirty-five white men have been thrown out of employment by the purchases already made. The Chinese have also offered the full value for the two ditches there. They are of a band just in from the railroad, have their interpreter with them and check on San Francisco.

New Mexico.

Aztec.—*Press and Telegraph*, June 11th: This mine reports thus for the 100 days from January 21st to April 30th: Receipts, 3,788 ounces. Expense account, labor and subsistence, 700 ounces. Making the dividends amount to 3,088 ounces; the average yield per ton, $75.76; the cost of mining and milling per ton, $14, and the net profit per ton, $61.76.

Chester.—The tramway is completed, and the Co. are expecting the wire rope and iron rolling stock on the 15th. Their 25-stamp mill will be ready to run about the 22d inst.

Arroya Honde.—From a three days' run the selected quartz averaged $25 to the ton. The company seems to be at loggerheads, and the mill has stopped for the present.

Humbug.—Now at work in this gulch,—South Park Co., working six men; Faulkner & Colman, eight men; Biddle & Lesperauce, six men; Peters and Jones, three men; California Co., eight men; E. H. Bergmann, nine men; the Denver Co. also talk of going to work.

Items.—A company of four are working Oreleans Flat with a limited supply of water. They average an ounce of gold to the hour's run....Two men are working Last Chance diggings, with small water and big pay....The companies on Willow Gulch are generally making good wages. Wherever water is to be had, miners are doing well.

Wyoming.

Telegram, Cheyenne, June 14th: Late information has been received from the Big Horn expedition, that the party is moving rapidly to its destination. All are in good health and spirits. They have had no trouble with Indians as yet.

African Gold Mines.—A telegram from Berlin says that Herr Hübner, sent by the Prussian Government to inspect the gold mines in the southern part of Africa, reports that they are worthless. M. H. started, we believe, in the fall of 1868, but we were not aware that he was sent by the Prussian Government.

The *Alta California* has reduced its price to 25 cents per week for the six-day edition, or 30 cents per week with the Sunday issue.

Mining Shareholders' Directory—Meetings, Assessments and Dividends.

——*Advertised in this journal.

The first through freight car from New York to this city arrived Saturday evening, and was unloaded to-day at the foot of Second street. It is the result of an experiment by Fisk, who intended, if it proved successful, to have a large supply of freight cars constructed on the plan of this one for the transit from ocean to ocean. The feature of the car now here is that it is mounted on axles on which the wheels can be moved to fit any desired gauge of track. In all devices heretofore used for changing gauge, grooves have been cut around the axle according to the number of changes to be made. It is claimed that these notches destroy the strength of the outside fibers of iron and weaken the axle. The device in this car obviates this difficulty, by inserting a stout feather key laterally on the axle, which secures the wheel at any point on the axle. It extends into the axle about five-eighths of an inch. The inventor of the patent is W. B. Snow, who came on the car. It was built by the Erie Railroad Company, and was freighted with boots and shoes, from Philadelphia, consigned to Hobart & Co., of this city. The trip was made without accident of any kind, and the experiment was pronounced successful. It is stated that the Erie Company will build 1,000 cars for this through trade. The trip was made in 14½ days from New York.—*Bulletin*, 20*th*.

The New City Hall.—The City Hall Commissioners are now prepared to receive designs and plans for the New City Hall, to be erected on Yerba Buena Park. Large premiums are offered for the first, second, third, fourth and fifth best designs, ranging from $500 up to $2,500 each. The competing plans must be handed in on or before the 1st of November next. Full instructions, suggestions, conditions, etc., have been prepared and published in pamphlet form, which will be furnished on application to the Commissioners at their office, southeast corner of Montgomery and Sacramento streets. See advertisement in another column.

A New Locher Steam Plow is in progress of construction at Oroville, which will soon be ready for trial. The Butte *Record* says that very many alterations are being made in the carriage portion of the machine, but the plows are operated upon the same principle as at first. The Messrs. Locher are building the machine entirely by their own labor. Their energy and perseverance are certainly deserving of success.

Scientific Press.—Saturday's number of Dewey & Co's. Scientific Press contains a fine engraving of the Bridal Vail Falls of the Yosemite, and a well written sketch of the same. It also contains a view of the suspension bridge now being erected to connect New York and Brooklyn. The Press is ably conducted and deserves a handsome patronage from the people of the Pacific coast.—*National Gazette, June 7th.*

Farming and Gardening.

Communications for this department are solicited from all parts of the Pacific States and Territories.

A New Grape-Vine Pest.

Mr. Isaac Richardson, of Santa Cruz, has sent us several insects which he found preying upon his grape-vines, growing about one mile from the sea shore, on the bank of the San Lorenzo river. Our correspondent also sent us several branches of the vine showing the manner in which the insect works. The land on which these vines grow is just above high-water mark, a sandy river deposit, and not very well calculated for the cultivation of the grape.

The insect belongs to what is popularly termed the beetle family, with hard or shelly-wing cases; is black and nearly half an inch in length. It commences its depredations after reaching its perfect state, and begins work in the crotch at the point where the young shoot is thrown out from the old vine, almost invariably working downwards, following the pith; sometimes moving across it, but seldom upwards. The vines soon become weakened by the excavations of this depredator, so that either the weight of the foliage or the winds breaks it down, thus causing great destruction. The specimens sent were in bloom.

Not being able to find the insect described among those injurious to the grape-vine, we handed the package over to Dr. Behr, of this city, an experienced entomologist, who reports it to be a *Polycaon Oviiollis;* adding that the genus *Polycaon* is restricted to America, and belongs to the family of *Psoides*. Only two species of the genus named have yet been discovered in California, neither of which are by any means common. Very little is known of the habits of this insect, and it would be interesting if our correspondent would watch the same, note the length of its life, its habits, etc.; and as this is the perfect form of the insect, learn, if possible, where it deposits its eggs; look closely for its *larva* in the spring, and note the time and manner of its progress to the perfect state.

So far as we are advised, this is the first time this insect has been found upon the grape vine. If any other party has observed it, we should be pleased to hear from them.

Our correspondent thinks that it is the same kind of insect as that which works upon the wild currant, which grows along the sea coast in that vicinity. We would suggest that he should examine more closely, and learn positively as to that matter. If the wild currant of the sea coast is its natural habitat, possibly it has in this instance attacked the grape vine, because found growing in an unsuitable locality, and consequently in an unhealthy state. Insects rarely attack perfectly healthy growth; at least they are more likely to be found upon that which is unhealthy.

Value of Overflowed Lands.—Some idea of the value of the land reclaimed from the Sacramento river may be formed from the following extract from the *Alta*, in reference to Sherman Island: "One field was lately rented at $5 per acre, the lessee to take possession after the present crop of barley is cut, and to surrender on the first of January. The rent for a year ranges from $15 to $20 per acre, or one-quarter the crop, if it is put in on shares, indicating that the total yield is estimated at $60 or $80 per acre, annually. After wheat is harvested, water is let into the ditches to moisten the soil, and the grain starts again from the roots, and from the scattered seed, and in 60 days three tons of hay can be cut from the acre, and then the same process is repeated, so that one crop of grain and two of hay are obtained in a year. Tilled land is sold at $75, and untilled land at $30.

A Kernel of Wheat—Tillering.

We last week endeavored to give some idea of the anatomy of a kernel of corn and of the bean; promising in the present issue to describe the component parts of a grain of wheat. In order that we may make the subject more fully understood, our engraver has prepared the accompanying Fig., 1, which represents a kernel of wheat, greatly magnified, and so dissected as to show, distinctly, its component parts. It will be observed that it has two skins, an outer and an inner one. The outer skin has been removed, in the engraving, from the two ends of the seed, and folded up about the center, at *b*. This may be easily done after a seed has been soaked a few minutes in warm water. The inner skin is then shown, *a*, *a*, which immediately covers the white or nutritive portion of the seed, composed principally of starch and albumen, and constitutes the chief bulk of the kernel; *c* is the little scale or cotyledon, through which the nutritive matter passes, after it has undergone a partial decomposition, evolving a small quantity of sugar, by which it is rendered more fit for the nourishment of the little plant, the germ of which is seen at *d*.

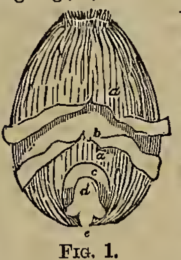

Fig. 1.

It will be observed that this germ exhibits three small projections or lobes at its base—a most important consideration, as will presently be shown; *e* is the point where the nutritive matter, the little scale and the rudimentary plant all unite. This point of union and the rudimentary plant or germ may be readily seen by a good eye, if a strong healthy seed is carefully split open. It will be much more distinctly seen if it is first soaked a little while in warm water. A small magnifying glass will be a great aid in such an examination. All these parts are essential to the growth of a seed.

It would be a useful exercise to those farmers who place but little importance upon the quality of their seed, if they would, in this manner, carefully study the lesson here presented, and note the marked difference between the appearance of the germ in a healthy and plump seed, and contrast it with that in a seed which presents a poor and shrivelled exterior.

The seeds of most kinds of plants possess such a structure that only one stem can be procured from them; but in some of the grasses, and especially in the cereal ones, the little protuberances, already alluded to, as seen at the base of the germ, in Fig. 1, render it possible for an indefinite number of stems to shoot upward, thus multiplying the capacity of the productive powers of the seed. It is certainly one of the wonders of plant growth that this principle should be so strongly developed in the cereals upon which man depends for so large a proportion of his food. Were it not for this, from eight to ten or twelve times the quantity of grain would be required to seed an acre, above that now needed, while the average *yield* would still be decreased.

This peculiarity in the wheat plant is still farther shown in Fig. 2, where the embryo in Fig. 1 is shown in a state of germination; one shoot, *a*, having left the sheath, another at *b* is seen just starting, while at *c* still another remains as yet undeveloped. In first-class California soil the number of stems so developed is so great as to quite stagger the belief of readers in other parts of the world.

Another peculiarity should also be observed in the manner in which the main roots of the plant are developed. Each upward projection of the germ has a corresponding development or projection below, from which descends a main root, which, as it grows, throws off laterals in search of food for its individual stem. Thus each stem is provided with its own particular roots through which it mainly derives its nutriment. If, in Fig. 2, Nature had provided for the development of only one stem, we should have seen but a single main root passing downwards.

This property of plants to multiply their stems is called *tillering* or *stooling*. The extent to which it may proceed depends mainly upon the character of the soil. Tillering implies a sort of instinctive faculty in a plant to take advantage of all the plant food within its reach. In carrying out this process Nature has also provided that the stronger and healthier, by this increase of stems, shall kill out the weak and worthless plants which can throw out but one or two stems—another argument in favor of carefully separating the poor from the good seed before planting; because the poor plant, which finally succumbs, during its brief and sickly existence, takes all its nourishment at the expense of the healthier.

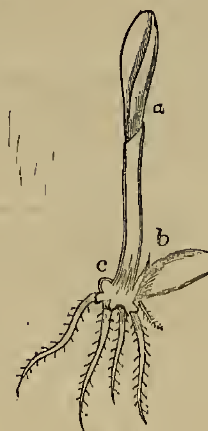

Fig. 2.

It is, moreover, observed that fully tillered grain produces larger straw, fuller and plumper ears and grain, than that which is but little tillered or growing in single, dual or treble stalks. This fact teaches another lesson, namely: that we should sow *thinly*, relying upon the superior quality of the seed for a large *tillerage*, rather than sow thickly with the view of producing a large number of single stalks or small stools.

In weak, undressed or exhausted soils, as has already been intimated, the tendency to tiller is much checked; the plants being apparently conscious of the inability of the soil to produce more than individual stems. Hence the practice to increase the quantity of seed in poor soils. Better decrease the seed and increase the dressing, and thus reap the advantages of tillering.

Although we have referred in these remarks more particularly to wheat, they apply equally to barley, oats and rye. In our next we propose to offer some hints on the preparation and proper condition of the ground for sowing grain, in which the *rationale* of the germination of seeds will also be incidentally shown.

Stock Raising in Nevada.

Our correspondent, "W. H. M.," who is now traveling through the eastern portion of the State of Nevada, writes very encouragingly of the agricultural capacities of that region—especially with regard to advantages which it presents for stock raising.

He writes that no portion of the world can produce fatter or better-fed beef cattle than are to be found raised upon the natural grasses in the vicinity of Elko, the great radiating point for travel from the Central Railroad to White Pine on the south and Idaho on the north.

During a recent trip from White Pine to Elko he noticed many ranches located in little valleys of the richest and most productive soil. On the west side of White Pine, the grass was very plentiful, affording an abundance of pasturage for sheep and cattle.

There were some five or six thousand sheep grazing upon the hill-sides near Elko, producing the most delicate mutton and the finest quality of wool. We copy, in this connection, the following paragraph from a late number of the Elko *Independent:*

> Nevada's resources as a stock-raising country cannot be excelled under any climate; in fact it is doubtful whether it can be equaled. In the summer season we have rich bunch grass, covering every hill-side with a luxurious growth, and in the winter, when our mountain ranges are buried deep in snow, the foot-hills and valleys are covered with the rich white sage, that can-not be surpassed by any of Nature's nourishing productions for the fattening of cattle.
>
> The impression of the majority of those who glide through the Great Basin by rail are antagonistic and highly unfavorable to our agricultural and stock-raising interests, owing to the fact that they see nothing of the pleasant little valleys that nestle beneath the snow-capped ranges that loom up and kiss the clouds on every hand. If shown the bunch grass and white sage and told that in it there is a juicy sweetness and nourishment that fattens our cattle and horses quicker and better than the blue-joint of Kentucky, they believe it not, until shown the gorgeous sights presented in the stalls of our markets by the display of fat beef and mutton.
>
> Of late several of the heaviest cattle men in California have discovered our resources and are extensively engaged in supplying the San Francisco market with beef, by rail, from along the Humboldt river and the adjacent valleys. Drovers are purchasing cattle in Texas, driving them to our State and fattening them for the markets of the Pacific coast, and in the speculation they are invariably successful in making a handsome profit.
>
> The wealth of our resources in this respect cannot long escape general attention, and it being simply an auxiliary to the great mining interests of the State, will lend an additional inducement for permanent settlement and the building up of good old-fashioned homes all along the great railway that binds together the Pacific and Atlantic oceans.

Fruit in Pajaro Valley.

Blackburn & Waters, of the Pajaro Valley Nurseries, inform us that they produced $500 worth of blackberries last season from a half acre of Lawton vines, three years old. The plants are now literally loaded with fruit and promise an abundant yield this season.

A lot of *Jocunda* strawberries that yielded some fruit last season, are barren this year, although in a favorable locality. They will be rooted out to give place to the *Longworth Prolific*, which is the best known variety for the coast country. Strawberries retail for twenty-five cents per quart in Watsonville and Santa Cruz this season. Messrs. B. & W. have a few Japanese and Spanish chestnut trees five years old that are in full bloom and will produce fruit this season.

There are several English walnut and black walnut trees in Santa Cruz nine years old that have borne three years. They are fine large trees. Some of the first fruit that these trees yielded was planted, and young trees ten feet high are now the result.

Messrs. B. & W. have a lot of cherry currants and *Fertile de Palueu* side by side. The cherry yields abundantly and is very fine, while the French sort is hardly worth caring for.

The apple crop will not be as abundant as last year; but there are enough on the trees to meet the demand, and they will be larger and finer, if less upon the limbs. The quality is likely to more than make up for the quantity.

Sheep are now being driven to the mountains in large numbers for pasturage, which is fast drying up in the valleys.

Grape Growing is becoming an important interest in Shasta county.

How to Treat Ground Bones—Superphosphates.

It is a fact well known to every intelligent farmer that no substance, however rich in fortilizing matter, can impart nutriment to plants while such fertilizing agent is in a dry state. Bones are naturally hard and dry, and when in that condition, either whole or ground, are no better than so much stone or sand as a fertilizer.

Before the plant can assimilate to itself any portion of bone nutriment, moisture must intervene to produce decomposition. If bones are placed in the soil whole, or in a crushed condition merely, the moisture can have access to only a very small surface; hence the process of decomposition must be slow. But if they are placed in the soil in the shape of a fine powder, the moisture will bring about such process much more rapidly. But a better way still is to start the decomposition before depositing the bones; as it will then go on more readily, and afford more prompt and satisfactory returns. This may be done to very good advantage in the manner described in our last issue, for treating broken or coarse ground bones, by mixing stable manure, ashes, etc.; or by the still better, but more expensive method of dissolving them in sulphuric acid. Bones in their natural condition, are known to the chemist as phosphate of lime, which is insoluble in water. When they are dissolved in sulphuric acid, we have a compound known as

Superphosphate of Lime,

Which is perfectly soluble in water, and immediately and entirely available as nourishment for plants. The preparation by the slower method produces but a slight change, leaving them still a phosphate of lime, in which the bones are only partially decomposed, and hence but slightly soluble in water, and to that extent only available for plant food. The balance of the decomposition, however, is then readily, though slowly, effected by the action of moisture, operating with the small amount of acids which naturally exist in the soil.

Manufacturing Superphosphates.

The production of superphosphates by the ordinary means of dissolving bone dust in sulphuric acid is quite expensive, and entirely unnecessary. Every 100 pounds of bones will require 40 pounds of acid, which should be diluted by four times that amount of water before applying it to the bones. If the bones are merely pounded into fine splinters, double the acid will be required. Equally good results, if not better, may, however, be obtained by pursuing the following course, by which every farmer who is not afraid of work may manufacture his own superphosphate from ordinary bone dust, or pounded bones:

Take a single horse cartload of dirt and pulverized peat or swamp muck, or, in the absence of such, the richest loam that can readily be obtained; spread it out into a dish-shaped form; spread upon the same a barrel of bone dust and a bushel of wood ashes, mixing the two; take a bushel of feculent matter from a dry privy vault, and add water enough to wet with it thoroughly the bones and ashes, then cover the mass with the muck, shoveling inward from the outside—building up the heap into a conical form. In 24 hours this mass will heat, and if not disturbed, or subjected to drenching rains, will continue hot for two or three months; but it will be fit for use in about three weeks—that is the decomposition of the bone will have progressed so far as to put it in a condition to furnish food immediately for plants. If allowed to remain six weeks, it would be better.

The addition of a little sulphuric acid would increase the action somewhat; but not at all in proportion to the added cost. Horse dung would answer the purpose of visit to the privy; but it would not be anything like as serviceable. In that case, however, the bones and ashes must be wet with liquid manure. In the absence of ashes, if pounded bones are used, the larger amount of wetting will be required, and double or treble the time. Much care must be exercised to prevent accident in handling the acid, and proper vessels must also be employed.

In the Application of Superphosphates

Much care and judgment should be used; else failure of any beneficial results will be sure to follow. It would be poor economy to apply superphosphates to soil already sufficiently charged with that agent; although it might be available in time, by successive croppings, but no immediate benefit would be shown. A lack of this knowledge—the presence of a sufficiency of phosphates—will no doubt account for most of the failures in the application of superphosphates. Again, if burnt lime (quick-lime) or burned oyster shells are applied to soil in connection with superphosphates, or if lime in that condition already exists in the soil, no good results can follow. Plain ground bone, or bone dust, which has been subjected to merely a partial decomposition in the compost heap is just as good, while it costs only about half as much.

The Chief Value of Bones

Arises from their furnishing mineral plant food in just that state in which it can be most easily appropriated by vegetable growth. The plant food contained in bones has already been subjected to a process of reorganization in the animal structure. Phosphate of lime is never found in nature, in any form, equal for fertilizing purposes, to that in which it is found in bones, while the ammonia, produced by the decomposition of the fleshy, gelatinous portion of bones, and absorbed by any proper substance, such as loam or swamp muck, is more valuable as plant food than when obtained from any other source. Phosphorus exists in bones as an *organic phosphate*, combined with *organic ammonia-yielding animal matter*, such as is found under no other condition.

When bones are subjected to great heat, as to the action of superheated steam or to calcination (roasting in a retort), this ammonia-yielding property, which constitutes an important percentage of their most valuable constituent, is lost.

Analysis of Raw Bones.

Raw bones, just as they come from the animal, contain

Moisture, about	12.00
Animal, or gelatinous matter (which yields about five per cent of ammonia)	35.00
Phosphate of lime,	50.00
Other matters,	3.00
Total,	100.00

In the process of slow decomposition in the compost heap, this animal matter throws off a large amount of ammonia, which is absorbed and held in mechanical suspension by the mass until it is applied to the soil and assimilated by the plant. In the production of superphosphates the heat given out by the combination of the water and sulphuric acid also tends to the production of ammonia, which, as far as produced, unites with the sulphuric acid, forming sulphate of ammonia, a condition in which ammonia is very available for plant food.

Curing Hay by Furnace Heat.—Alderman Mechi, a celebrated English agriculturist, writes to the London *Times* that he shall hereafter arrange to make his hay by furnace heat. The apparatus consists of a coke furnace and a fan, by which the heat is driven through a small chamber filled with grass. In fifteen minutes it is converted into hay, sweeter and greener than can be made by sun-drying; it works in all weathers, and dries grain, corn and roots as well.

Eighty bushels of Norwegian oats to the acre were raised on a ranch near Antioch, Contra Costa county, this year.

What I Know of Farming—No. 23.

About Tree-Planting.

I have had so little experience in tree-planting that I should have preferred to say no more about it; but letters that have reached me imply that the ignorance of others is even denser than mine. For the sake of those only who are conscious that they know nothing, yet are not unwilling to learn, I venture a few timid suggestions with regard to tree-planting.

I. Ten or twelve years ago, I bought a pound or more of locust seed rather late in the spring, scalded it by plunging at nightfall the little cotton bag which held it into a pot of boiling water, and letting the seed steep and steam in the bag till next morning, when the seed was planted in rows in a newly broken bit of poor old pasture land. This was a mistake; I should have given that seed the richest available spot in my garden, to say nothing of planting it as early as April 20th. My locusts came up slowly and grew feebly that year, not to speak of the many seeds that did not sprout at all. Still, many came up and survived, and my place is this day richer for them. It might have been still richer had I seasonably known more.

II. What I would now advise as to locust and most other trees is, that the best seed be procured in the fall, or so soon as it drops from the trees; that part of it be sown in drills, two feet apart, with two inches between seeds in the drills, and that the richest of dry, warm garden soil be devoted to this purpose. Fill a large box with rich loam, stir four ounces of seed into this, and set the box in a cool cellar where frost does not enter, and here let it remain till April; then take out the seed and earth together, and sow in drills as above. If some one who cuts locust during the winter or spring will allow you to trace the smaller surface roots from the new-made stumps and cut or dig them up, cut fifty or a hundred pieces of root the size of your finger each two feet long, and plant these, about May 1, in the places where you want locusts to come forward most rapidly. Some of them may not grow, but I think many will; and, from all these sources, I judge that you will obtain a good supply of young trees. Let those you start from the seed get two years' growth before you take them up, and set them where you want trees, whether in your present woods, in rugged, rocky pastures, on the sides of steep ravines, or around your buildings. You cannot fail to obtain *some* trees if you follow these directions.

III. Begin early this fall to gather chestnuts, hickory nuts, walnuts, white oak acorns, etc., to plant. Select the largest and finest nuts, giving the preference to those which ripen and fall earliest. Keep them in cool, damp earth in some barn cellar where rats and mice cannot reach them, and persist in collecting till December. Then plant a part in your garden or in any rich ground where they are not likely to be disturbed; letting the residue remain in the boxes of moist earth where you first placed them till early spring, then plant these, like the former, in rows two feet apart, with six inches between seed and seed in each row, and give the rows careful culture for two years; after which, set them where you wish them to grow.

I venture to suggest that he who has a rugged, stony hill or other lot which he wishes to surrender to forest should plow it, if it can be plowed, next September or October; if too rocky to be even imperfectly plowed, dig up the earth with pick and spade, and sow it thickly with hickory nuts, walnuts, chestnuts, locust and other tree-seeds, expecting that some will be dug up and carried off by squirrels, etc., and that some will fail to germinate. Go over it with hoes the ensuing June or July, killing all weeds and other infestations; and, nearly a year later, repeat the operation, taking up young trees from your garden or nursery, and filling them in wherever there is room. Plant thickly in order to force an upward rather than a scraggy growth; and so that you may begin to cut out the superfluous saplings for bean poles, hoop poles, etc., three or four years thereafter. Cut late in winter or early in spring, so that the stumps will each throw up two or more shoots or sprouts, which usually grow much faster than the original tree did. And the process of thinning may thus be continued indefinitely, while the choicer trees are allowed to attain their stateliest proportions. And thus a rocky, sterile hill-side or knoll may be made to yield a crop annually after the first two or three years from planting, while growing trees of decided value. I judge that almost any land within fifty miles of a great city and not more than two miles from a railroad depot or from navigable water may thus be made to earn a good interest on $100 per acre, after meeting all the cost of breaking up and planting. I confidently assert that many thousands of sterile, rocky acres, which now yield less than $10 per acre annually in pasture, would net at least double that sum to the owner if wisely devoted to forest trees.

I have a hearty love of forests. They proffer gentle companionship to the thoughtful and rest to the overworked, fevered brain. Our streams will be fuller and less capricious, when we shall have re-clothed our rugged slopes and rocky crests with trees. Timber grows yearly scarcer and dearer, when it ought to be becoming more plentiful and accessible, and *would* be if we devoted to trees all the land which we cultivate at a loss or fail to cultivate at all. Let our boys be incited to gather seeds and plant nurseries; let young trees be bought by the thousand where they now are by the dozen, and let us all coöperate in covering our unsightly rocks and making glad our waste places by a superabundance of choice, thrifty, healthy trees.—*Horace Greeley*.

Pajaro Valley.

This is one of the finest agricultural districts in the State. Situated at the head of the Bay of Monterey, it reaches from the water to the Santa Cruz Mountains, some twelve miles, spreading right and left among the hills and ravines. It is nearly level, and presents a scene of rare beauty from every side.

t is Watered

By several streams that revel amidst sycamores and cottonwoods. The mountains rise in well-defined grassy ridges or spurs, divided by cañons filled with dark evergreens, and form a background of massive beauty. Wonderful indeed is this whole coast country, whether viewed from the mountain heights, seen among rugged hills, enjoyed in the broad winding valleys, or lost in dark deep ravines. Everywhere, whether in a wild or a cultivated state, the soil is prolific of vegetation. A vital sense of beauty pervades the scene, a companionable grandeur and magnificence, greatly in contrast with the vast and profound desolation of the mountains and plains of Nevada and Arizona.

The contrast between the coast mountains and valleys, and the Sierra Nevada mountains and valleys, are also wonderful. Here is a denseness of growth and a luxuriance of vegetation that is incomparable. I am disappointed in

The Town of Watsonville;

Not as to its size, for it is large enough, but it has a slovenly and shabby appearance, not at all in harmony with its surroundings. Its streets and sidewalks are rough and half civilized. Fences that might do in a back pasture front the streets. Accumulated rubbish greets the eye at every turn. A little judicious repairing, paint and whitewash would be salutary. It is not expensive and magnificent structures that I desire to see in a country village like this, but a little neatness is certainly in good taste, and that is what is lacking.

Business is very fair in Watsonville; but the complaint of *hard times* is getting to be chronic everywhere. The crops are good—everything very promising.

A Railroad Needed.

Santa Cruz county needs a railroad to bring it into more direct communication with the world. Coasting vessels, steamers and stages now run to other parts; but such slow conveyance is insufficient. I don't mean to insinuate that this country should be taxed to build a railroad for the benefit of capitalists; but the people themselves should take stock in a joint company, so organized that no advantage can be taken to swell the grasping avarice of pretending benefactors. Railroads are needed; but no country should be despoiled to build them for greedy companies as a means for saping the very life out of industrial pursuits. Railroads should benefit, not ruin a country; assist, not impoverish it. But until some things change, not much hope remains.

S. H. Herring.

Immigrants.—Quite a large immigration is coming into the State *via* the Southern Overland Route. The San Bernardino *Guardian* says it appears to be made up of a better class of people than usual, and that large quantities of stock are being brought along for sale.

Notices to Correspondents.

We have on hand several letters which are either without any signature or with initials merely. We are obliged to request the full name of correspondents before we can publish their letters. Any signature can be given for publication, but the editors must know the real name.

P. A., Mariposa.—The specimen you sent us is asbestus, of which several varieties are found in this State. It is of no value.

Horticultural Visitors.

Messrs. Wilder, Downing, Ellwanger and Clark, four of the most distinguished horticulturists of this, or any other country, arrived in this city on Tuesday evening last. Each of the gentlemen are accompanied with their wives, as all men should be when they travel for pleasure. They were met on the Summit by a delegation from this city and vicinity, consisting of Prof. Carr, of the University; A. S. Hallidie, Pres. Mechanics' Institute; S. W. Shaw, Esq., and others. It was about sunrise on the morning of Tuesday, and high up among the snow-clad summits of the Sierras where the California delegation met our Eastern friends, and bid them welcome to the Golden State. A most appropriate and bounteous feast of our native fruits and wines was spread for the company as soon as they got down into the foothills. The party are stopping at the Cosmopolitan. On Wednesday they visited several of the public institutions. On Thursday they were the guests of Mr. Ralston, at his palatial residence at Belmont. At the present time they are enjoying themselves in visits to some of our most extensive and beautiful suburban orchards, vineyards and gardens; which will be supplemented by more extensive tours into the great grain and fruit valleys of the State, and visits to the Geysers, Yosemite, Big Trees, Calistoga, etc.

◆

Microscopic Life.—The lecture before the Mechanics' Institute, last Saturday evening, was delivered by Dr. Henry Gibbons on *Microscopic Life.* The doctor handled his subject in an interesting manner, and at the same time took advantage of the opportunity to indulge in a few pleasantries. The lecture abounded in useful information condensed into the small space allowed for treating of so extensive a field. We are unable to devote as much space as we would like to the lecture, as our index this week deprives us of a large part of our room.

◆

Compressed Asphaltum Block Pavement.—A section of this pavement was laid this week on Montgomery street. It is made up of blocks, about six inches long and four inches deep, with grooves on each side for the admission of sand, gravel or other fine material. The blocks are laid somewhat after the fashion of the Nicolson Pavement. The blocks are manufactured at the Mission by Messrs. Bennet & Skinner.

The Alvarado Beet Sugar Factory.

We have several times taken occasion to refer briefly to the beet sugar manufactory now in process of erection at Alvarado, some twenty miles south of this city, on the east side of the Bay. It is a little singular, in view of the encouraging facts connected with the manufacture of beet sugar in Europe, and the great promise held out by the superiority of the climate of this State for the production of saccharine matter in the beet, that so little energy has hitherto been manifested with regard to establishing the business in California. Years have elapsed since the first factory was projected here; but as yet no practical results have been achieved. It is such a common-place thing to notice the organization of companies with large capital, for all manner of enterprises, that when we observed the announcement of the organization of the Alvarado Beet Sugar Company, with its quarter of a million capital, we paid but little heed thereto; but a visit to the Union Foundry, in this city, a few days since, has fully satisfied us that this company, at least, means business, and know well what they are about.

Passing through the various departments of the foundry—the moulding room, the machine shop, the boiler room, the yard, etc.—we everywhere noticed large amounts of heavy machinery, quite different in character from that ordinarily seen in our foundries, which, on inquiry, we learned was intended for the Beet Sugar Factory, now in process of erection, as above, at Alvarado. The building is already in a forward state of construction, some idea of the size of which may be formed from the fact that 78,000 feet of lumber is to be used in its construction. To fill this large structure the following machinery is now in process of construction at the Union Foundry, a part of which has already been forwarded to the site of the mill, and all of which is in a forward state of completion:

Four tubular boilers, each 54 inches diameter, 16 feet long, with steam and mud drums, all complete and embracing everything in the way of the latest improvements.

Two engines, 14x30, of first-class finish, and fitted with Scott & Eckart's automatic cut-off. One small engine, 6x12.

One vacuum pan and two air pumps, four saturation pans, five filters, two filter pumps, one beet grater, one beet breaking machine one beet washing machine, three mortejus, (tanks in which sugar and syrup is elevated from one floor to another), also, a number of large sheet-iron tanks for various purposes about the works.

In addition to the above is a multitude of shafting, pulleys, pipes, pumps, and various fittings incidental to a complete sugar manufacturing and refining establishment, capable of working up 50 tons of beets per day. All the machinery and fixtures are made at the Union Foundry, with the exception of the centrifugals, which will come from the East.

All the work connected with this machinery is being done in the most thorough manner. The reputation of the Messrs. Booth & Co. is always a guarantee that everything which goes out of their establishment shall be, not only first-class as a whole, but neat and well designed in all its parts. The engines, which were just being put together at the time of our visit, are most elaborately finished, and fitted up with the most complete arrangements known to mechanical experts, for oiling and adjusting. The regulating is done with the Scott & Eckart automatic cut-off, which fact is an assurance that it will be well done. Nothing has been omitted which would add to their utility or beauty. The factory will be ready to start about the first of September, or as soon as the beet crop comes in.

Mr. E. W. Dyer, whose name is largely connected with the enterprise, has entered extensively into the culture of the beet, for the supply of the factory. We believe, however, it is the intention of the company to depend chiefly for their stock of beets upon the neighboring farmers, who will receive a fair price per ton for the same, delivered at the factory. The operation of the works will be under the joint direction of Messrs. Otto, Klind and Bouestel, each men of large experience in the business, the two former of whom were long and, until quite recently, engaged in some of the most extensive beet sugar factories in Germany.

◆

University of California.

The Board of Regents met on Tuesday afternoon, for the especial object of electing a President of the University. For the purpose of getting as good an officer as possible, the Trustees had sent to various places for recommendations of especially good candidates. As the result of this action (we presume), the following gentlemen were nominated: Dr. John S. Hart, Principal of the State Normal School of New Jersey, and formerly of Girard College, of Philadelphia, recommended by Senator Stockton, Bishop Odenheimer, Governor Hoffman, and others; Gen John Gibbons, of the United States Army, at present stationed at Salt Lake, recommended by Gen. William T. Sherman, Gen. George B. McClellan, Gen. Franklin, and other distinguished army officers; Prof. D. C. Gilman, of the Sheffield Scientific School, Yale College, recommended by President White, of Cornell University, Prof. Silliman, of Yale College, Rev. Dr. Bellows, of New York, Prof. Brewer, of Yale, Dr. Thompkins, of New York, and others; Prof. Trowbridge, formerly of the Michigan State University, but latterly Superintendent of the Novelty Iron Works, of New York, a graduate of West Point, recommended by Gen McDowell and the entire Faculty at West Point; Dr. W. T. Lucky, of the California State Normal School, recommended by Prof. C. W. Prichett, of the State University of Missouri, John B. Clark, of Missouri, and others; Prof. Joseph Le Conte, of the California State University, recommended by several of the Regents, who had had an opportunity of witnessing his efforts in the University. Gen. Benj. Alvord and Mr. S. F. Butterworth were also nominated, but declined. The ballot was taken, and resulted as follows: Dr. Hart, 1; Prof. Le Conte. 3; Prof. Gilman, 8. The election of Prof. D. C. Gilman was then made unanimous, and the President was instructed to notify him of his election, and ask him, in case he accepts, to name the day when he will enter upon the discharge of his duty.

Mr. Louis Sachs was unanimously re-elected Regent.

The Toland Medical College, of this city, sent in a communication, looking to an affiliation with the University. The matter was referred to the Executive Committee. A resolution was adopted, authorizing and requesting Dr. J. Le Conte and Dr. E. S. Carr, of the University, to deliver a lecture in the Toland Medical College during the approaching vacation of nine weeks.

Mr. J. T. Doyle introduced a resolution (which was unanimously adopted) providing for the delivery of lectures by the Professor of Agriculture, Agricultural Chemistry and Horticulture, in different localities throughout the State, upon subjects connected with agriculture, likely to be of most interest and value to the people. These lectures are to be free, and public notice is to be given in advance of the place and time. During the lecturing tour, the Professor is to collect statistics concerning the crops, flocks and herds of the State, with a view to publication; and the Board of Regents are to procure rare and valuable seeds for distribution throughout the State.

Mr. Doyle likewise introduced resolutions for the establishment of a branch of the Mechanic Arts College in this city; two lectures weekly to be given by the University Professors and other eminent gentlemen, and proper arrangements for this purpose to be made with the S. F. Mechanics' Institute.

A resolution was offered by Mr. Butterworth for the organization of a Law Department. Hon. S. J. Field, of the U. S. Supreme Court, was unanimously elected Professor of Law. The public commencement is to be held on July 20th. The Board then adjourned until July 19th.

The action of the Board of Regents will be welcomed on all hands. The resolution with regard to the agricultural lectures is especially important, and shows a most commendable determination to make the University an important element in the development of the State. We shall no longer have a dead institution, merely drawing funds from the public treasury, but a live power acting amidst the practical life of the land, directing and guiding those who will not, or cannot, devote themselves to a scholastic course of study. All success to our live University!

◆

Stetefeldt Furnaces.—Three of these furnaces have recently been constructed at the Union Foundry, in this city, one each for the following localities: Monte Christo, White Pine; Mineral Hill, near Elko, and a third for the Manhattan mill at Austin. The first of these improved furnaces, it will be recollected, was put in operation at Reno, where it has given the highest satisfaction, and has led to the subsequent orders, as above.

In addition to the furnace above mentioned as having been shipped to Mineral Hill, the Union Foundry has also recently forwarded to the same locality a quartz mill complete, with engine, stamps, etc.

◆

The Fox Copper Mine.—Mr. Thorpe, the owner of this mine, near Colfax, is still persevering in the work of development. He is now down something over 300 feet and is finding very good ore, but somewhat scattered in strings and benches. He is confident that the ore will soon come together in a mass, when he expects to have one of the finest mines in the world. The perseverance of Mr. T. is certainly deserving of success to the extent of his highest anticipations.

◆

The Standish Steam Plow, building by a party in South Boston, Mass., will soon be on its way to California. It has a number of improvements on the original machine built at Martinez, in this State, and is made stronger in some of its parts. The new plow is 19 feet in length and will plow from six to nine feet in width. It is the intentions of the proprietors to work the machine briefly at Chicago, and then bring it to California as originally proposed.

◆

The True Policy.—Mr. L. Combe, near San Diego, is feeding a large number of silk worms this season, and proposes to reel the silk himself. That is the true policy, and should be generally adopted by silk-growers throughout the State. The reeling for small cocooneries can be done by the women and children, at their leisure, and in all cases will contribute to that diversified system of labor on the farm which is so essential to successful husbandry anywhere.

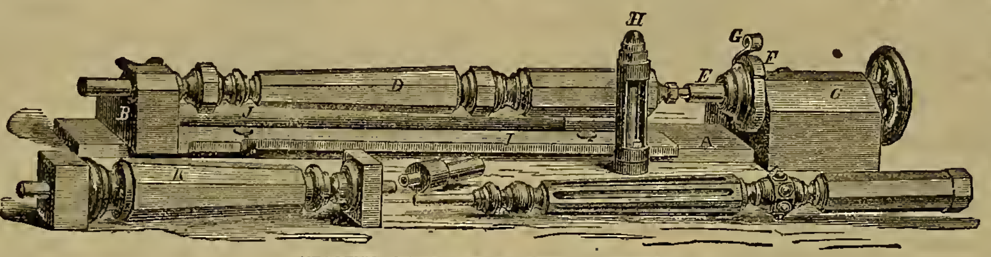
◆

The Century Plant in the fine grounds of Major Kirkham, on Oak street, near Seventh, Oakland, will probably bloom soon. It is about twenty-five feet high, and the stalk is from eight to ten inches in diameter at the lower part. The leaves rise seven feet from the ground, and the buds are now four or five inches in diameter.

Guide for Planing Machines.

This is an invention which will interest the many workers in wood on our coast. In dressing much work by hand there are many disadvantages to be encountered, and often recourse must be had to the drawing-knife, chisel or rasp. By this machine it is claimed that a great advance in this respect is made. It will dress the sides of stair balusters, chair, table and desk legs, etc., either parallel, tapering, concave, convex or waived, and will flute, groove or reed the same. Stuff which, when finished by hand, must be discarded on account of knots and curls (the handsomest, when smoothly finished), is dressed almost as readily as straight-grained wood, and it is claimed that the device will do the work of twenty men per day.

The main features of the device are the attachments for holding, adjusting and feeding the stuff past the rotary cutter. In the engraving, A is the bed upon which are placed the spindle or centering heads, B and C; B being adjustable vertically, and having a center-pin for holding the blank, or a quick cone-shaped hole for the turned end of the blank. The head, C, has an adjustable spindle, E, and is itself adjustable along the bed to receive different lengths of blanks. The spindle, E, carries a templet or dividing plate, F, with spacing notches, for either four, six, eight, ten, or twelve sides, as may be required, for different kinds of work. The notches of the dividing plate engage with a spring catch, G, which holds the plate in the desired position while the cutting is performed. H represents a rotary cutter rising through the table of an upright shaping machine upon which the device is used. A guide pattern, I, adjustably attached to the bed, A, serves to gauge the cutting. The operator takes hold of the hand-rail, J, pushing the machine from him, and at the same time bearing the guide-pattern, I, against the mandrel, H. The machine is then drawn back, and lifting the spring-catch, G, with the left hand, and turning the blank with the right, one space, another side is presented to the cutting tool, thereby dressing the sides alike, and making any number of pieces exactly similar. For fluting or reeding the work, the opposite edge of the guide pattern is swiveled out to correspond with the length of fluting desired, and bits, corresponding to the intended ornamental design, take the place of the straight ones—the guide pattern, as before, is brought to bear against the mandrel. The construction is simple and does not require a skilled hand to use it. It is said to be capable of dressing from 180 to 200 octagonal stair balusters daily. For further information, or for the purchase of State or Territorial rights, apply to the patentee, Franklin Keagey, Chambersburg, Pa.



KEAGEY'S GUIDE FOR PLANING MACHINES.

◆

The Overland Monthly.—With the July number (just received) commences the fifth volume of the *Overland Monthly*, which is now published by John H. Carmany & Co. This magazine is justly one of the boasts of California. Most excellently edited, and of fine typographical appearance, it has raised the literary reputation of the State to a high place, and given her a rank usually obtained only by much older countries. It has in the United States but one rival, the *Atlantic*, and in comparison with this it by no means suffers. Containing in each number some valuable article on our resources, and thereby making our capabilities better known; bringing to light the literary merit of our State, which otherwise, we fear, would remain concealed; always teaching and educating the tastes of our people;—it bears honestly on its title "devoted to the development of the country."

Laborers Wanted.

While here in the city there is still complaint among the laboring class that they can obtain no work, there likewise continues to be complaint in the interior that there is a scarcity of workmen.

San Francisco is a very good place, but it is not the only one on the coast, and we hold that it is much preferable to work hard and fare well in the country, than to have nothing to do but starve in the city. There is plenty of opportunity for the laborer at present, if he is willing to seek it. The harvest is commencing, and farm laborers are wanted. The mines are being worked and miners can find employment. But men will stick to the city when there is every reason for being somewhere else.

The working men generally of this city voted against the Southern Pacific Railroad subsidy, although probably not one in ten would have been willing to have left here, and to have gone to work on the road. And now they refuse to go to the country where they can have good fare and plenty of work. Their complaints are therefore apparently fictitious to a great extent. Very sensible advice is given in the following to a young man taken from the Marysville *Appeal:* "He had better go into the foot-hills or on the plains back of the city, near what will eventually be a station of one of our railroads, get from fifteen to thirty acres of good land, then go to work, fence it, plow it up, put it in order, grow small fruits—currants, gooseberries, strawberries, grapes, blackberries, raspberries; get up a grand asparagus bed; raise chickens, pigs and turkeys, and stick to his business; have a cottage, and get a wife to help him—and he will come out all right, and make more money than some men with a thousand acres of land. Won't you, and others in like condition, think of this advice, and then put it into practice?"

◆

The Burleigh Rock Drill is being tested in England. At a trial at Deptford the following results were obtained, according to the London *Mining Journal*: Drill No. 1, blue Aberdeen granite, two feet two inches in four minutes. Drill broke. No. 2, same, two feet two inches in three minutes ten seconds. Drill broke. No. 3, same, two feet two inches in two minutes forty seconds. No. 4, same, two feet five inches, on the slant, in three minutes ten seconds. No. 5, Cornish granite, two feet four and a-half inches, in three minutes. Fracture occurred in the stone. No. 6, same, two feet five and a-half inches in three minutes twenty-four seconds. Fracture in stone. Nos. 3, 4, 5 and 6, with same drill, nine minutes five seconds.

The London *Engineer*, and also *Engineering*, speak very favorably of the working, and both state that hard rock could be bored, according to the trials, at the rate of one foot per minute. *Engineering* is particularly emphatic. "These working results" (obtained in America), it says, "in conjunction with the experiments which we recently witnessed, in our opinion establish the Burleigh drill as being, in every respect, the most perfect and practical drilling machine with which we are acquainted."

◆

Sewing Machine Manufactory in Grass Valley.—Messrs. Snowdon & Gray have started a sewing machine manufactory in Grass Valley, and will soon be able to turn out two machines each week. Such enterprises should be encouraged.

Patents and Inventions.

A Full List of Patents Issued to Pacific Coast Inventors.

[From Official Reports to DEWEY & CO., U. S. and Foreign Patent Agents, and Publishers of the Scientific Press.]

For the Week Ending June 14th.

Snow Plows.—Thomas C. Churchman, Sacramento, Cal.

Separating and Refining Metals.—C. S. Eyster, Denver, Colorado.

Dove-tailing Machine.—Elander Heath, San Francisco.

Sheet-Metal Pipe Forming and Threading Machine.—M. K. Pierce, Callahan's Ranch, Cal.

Construction of Cane-Seat Chair.—C. M. Rohr, Portland, Oregon.

Wheel for Vehicles.—John D. Ross, Truckee, Cal.

Coloring Photographs.—Robert Winter, San Francisco.

Spring Hinge.—James Bidwell, San Francisco, assignor to himself and James McMeehan, same place.

Rein Holder.—Jacob Herkimer, San Francisco.

Furnace and Condenser for Reducing Cinnabar and Other Volatile Ores.—Richard F. Knox and Joseph Osborn, San Francisco.

Note.—Copies of U. S. and Foreign Patents furnished by Dewey & Co., in the shortest time possible (by telegraph or otherwise), at the lowest rates. All patent business for Pacific coast inventors transacted with greater security and in much less time than by any other agency.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co's Scientific Press American and Foreign Patent Agency, the following are worthy of mention:

Furnace and Condenser for Reducing Cinnabar and Other Volatile Ores.—R. F. Knox and J. Osborn, S. F.—The name of this furnace explains its purpose. It also aims at obtaining a condensed metal in a good condition, and without allowing the escape of deleterious vapors. The following brief description will give a general idea of the invention: At one side of the shaft or chamber of the furnace is placed the fire-place, and on the other side, a little higher up, is the discharge or draft opening. Both of these are guarded by a grating. The furnace is contracted gradually in width towards the bottom, and an incline conveys the refuse ore to the floor. The upper end is closed by a small door, where the ore is charged. The chamber is kept constantly filled with ore, which is constantly settling to the bottom, as it passes down being roasted, and the vapors being carried off through the draft opening and a pipe to the condensers. These last are iron vessels, connected together by curved pipes, so arranged that the vapors must pass as far as possible, and thus be exposed to the greatest cooling influence. These condensers are cooled by apparatus for holding water, and there is an arrangement for keeping the pipes clear. At the end of the series of condensers is a suction blower or other suitable device for obtaining a proper draft in the furnace. The mercury or other metal escapes from the bottom of the condensers. A correspondent of the S. F. *Bulletin*, writing from the Knoxville quicksilver mine, Lake county, where this furnace has been tried, says: "It runs all the time, till something gives out. The ore and fuel constantly go in, and the quicksilver and *debris* constantly come out, and there is not a noxious exhalation about the work. To this last fact I can testify from my own observation. The air is as sweet and as pure as there is in any spot in California. Mr. Knox is well satisfied with the workings of his plans, though he thinks he can build both furnace and condenser with some slight improvements on these."

Rein-Holder.—J. Herkimer, S. F.—To many who drive a good deal, this device for holding the reins will prove of value, as when on a straight stretch, and the horses can be left to themselves in a great measure, its use will relieve the hands, which otherwise become tired from the strain on them, and from keeping them a long time in a cramped position. It is especially useful, moreover, as a ready and safe means of disposing of the reins when the driver desires to leave the horses standing. On the dash-board or other part of the vehicle, is fastened the base plate of the device, on which is a vertical standard with a small shaft extending from it parallel with the plate. Placed eccentrically upon the shaft is a small cylinder or roller, which rotates so as to bind the reins against the plate, when they have been placed beneath it, and it has dropped by reason of its unequal balance. The roller either is covered with an elastic band, or is made entirely of india-rubber. Near the top of the standard, on the side away from the driver, is a lug or projection which limits the revolution of the roller, and prevents it from turning completely over, so that when it has been raised or partially turned by introducing the reins beneath it, it will fall back of its own weight and bind them. Another curved lug or ear on the plate prevents the reins from slipping beneath the roller.

Wheel for Vehicles.—J. D. Ross, Truckee, Cal.—This device for constructing wheels, which will be exceedingly light, and at the same time very strong, will attract considerable attention. There are now in this city, at Kimball's factory, four wheels which, with the tires, weigh only 24 pounds! The method of construction is simple, and consists in placing the spokes alternately on one side and the other of the center line of the hub, and in introducing, between the hub and the felly, a rim (or more, if necessary), so that all the spokes from one end of the hub rest against one side of the rim, and those from the other end against the other side, all being fastened to it by light clips. In this way the wheel is greatly strengthened, and the hub is relieved, so that if it is kept screwed up tight, the tire will not be loosened even if the spokes become loose in the hub, as this rim acts as a second hub, which always maintains its full size. In this way a very high wheel can be used, if desired. For rocking or trotting sulkies this construction is especially adapted, and promises to come quite extensively into use.

Double Reversible Door Butt.—J. Bidwell, S. F.—This invention relates to an improved butt for doors opening in both directions, either inside or outside, and which is called a double reversible butt. It consists in making the leaves of the butt, which are secured to the door and casing, of a sufficient width to extend entirely across the thickness of the door, and in constructing peculiar knuckles or joints at each side of the leaf, so that when the door is opened in either direction, the knuckles on the opposite side will separate, while the ones on the opening side will hold and turn. It also consists in casting upon the leaves of the butt a hollow tube or barrel, which enters the door and casing at right angles to the butt, through which a strong spiral or other spring extends, which serves as a spring to keep the door closed. Due regard to appearance is had in constructing this device.

Construction of Cane-Seat Chairs.—C. M. Rohr, Portland, Oregon.—The object of this invention is to insure increased durability in the seat of the common cane-seat chair. By rounding the inner edges of the frame of the seat, the cane cannot be cut, as is often the case where the usual sharp square edge is employed. Moreover, the holes in the frame, through which the cane-strips pass, are bored, not vertically, but at an angle with the vertical, one hole inclining outwards and the next inwards. These changes in construction seem very simple, but we are informed they make a great difference in the wear and tear of the chair, and increase its durability to a greater degree than one might think at first sight.

MINING SCHOOL.

Mosheimer's Practical Mining School

Will be reopened by the FIRST OF JUNE, and practical instruction given in all branches of Assaying, Crushing, Amalgamating Concentrating, Smelting and Refining Ores; also Erecting Furnaces and Reduction Works of every kind. To give all miners a chance to learn Assaying of Ores (what everyone ought to) I have reduced my former charge for

Assaying Ores	$ 50.00
To work Gold and Silver Ores	100.00
Smelting and Refining, including Assaying	150.00

Many gentlemen who have been taught in my establishment will hear testimony that in a few days they learned more than they expected to learn in a month. Before going into mining, every man ought to know how to test ores, and then he will go to work with prudence and never fail to be successful. Apply to

J. MOSHEIMER.

Office, 328 Montgomery street; Works, 2,005 Powell street, San Francisco. 22v23-3m

---

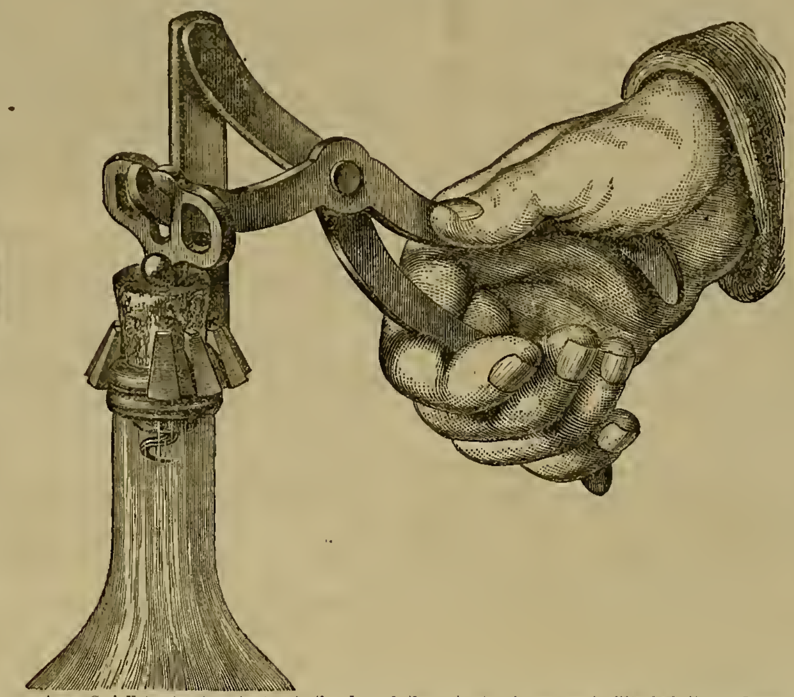
PATENT BROKERS,
No. 314 Bush Street, San Francisco.

PATENTS BOUGHT AND SOLD ON COMMISSION.

For the benefit of those who live at a distance from the city, we give below a brief description of a few of the valuable Patents which we have in our office. It may be well to state here that no Patent is received by us for negotiation until it is first endorsed by reliable experts, to whom each is subjected for acceptance or rejection. We treat all patents alike, recommending only where true merit is found in the invention.

MORTON'S CORK EXTRACTOR.



A new Cork Extractor, in order to take the place of other extractors in use, must either be better or cheaper than they. It is not claimed that the one represented above is cheaper than the Clamp Extractor with its toothed jaws, or the Needle Extractor with its self-adjusting cross bar, yet it is claimed that for power, durability, convenience, general application and practical utility, it is superior to either of them, or any other cork extractor yet invented.

With this contrivance the tighest cork can be drawn with a mere nominal outlay of strength, and without any risk of cutting or bruising the hands. The manner of using, and the advantages gained, can be fully understood by examining the above cut. The cork can be drawn without disturbing the contents of the bottle or spattering them over the hands or clothing of the operator. They are manufactured out of the best material, and will be furnished plain or silver-plated, at manufacturing cost, to parties purchasing Rights. The Patent is placed in our hands for sale, and we are allowed to dispose of the States and Territories west of the Rocky Mountains at a very low price. Call and examine the Extractor, or write for full particulars.

WIESTER & CO.,
314 Bush Street, San Francisco.

MEDICAL DEPARTMENT
— OF THE —
University of the Pacific.

The EIGHTH COURSE OF LECTURES will commence on TUESDAY, JULY 5TH, and continue five months, with an intermediate vacation of two weeks.

Important to Assayers.
Crucibles.
The Patent Plumbago Crucible Co.
Manufacturers of all kinds of

Melting Pots, Portable Furnaces,

CRUCIBLES, and other fire-standing Goods,

Battersea Works, London.

THE MORGAN PATENT CRUCIBLES have uniform quality, never crack, withstand the greatest heat without danger; heats more rapidly than any other; change of temperature has no effect on them; stand on the average forty to fifty pourings.

CERTIFICATES:

United States Branch Mint, San Francisco, Cal., March 12, 1869—Messrs. A. S. Hallidie & Co., Agents Morgan Crucible:—I have carefully tested the Morgan Patent Plumbago Crucibles purchased from you for the U. S. B. Mint, and cheerfully certify to their superiority and economy over all other Crucibles used by and under me. They are fully what you represent them, and I shall continue to use them in preference to any other. J. M. ECKFELDT, Melter and Refiner, U. S. B. Mint.

Eagle Brass Foundry, 206 Fremont street, San Francisco 12th March, 1869—Messrs. A. S Hallidie & Co., 519 Front street—Gentlemen:—We have used and tested the Morgan Patent Plumbago Crucible, for which you are agents, and pronounce them superior to and cheaper than any Crucible used by us heretofore. GREENBERG & MOORE.

Messrs. A. S. Hallidie & Co :—We have thoroughly and severely tested in every way the Morgan Patent Plumbago Crucible obtained by us from you, and find them superior to any we have yet tried, although we have used every pot obtainable in this market, we have none equal to the above, and concede your claims for them. We think they will average 45 pourings of brass. GALLAGHER, WEED & CO,, California Brass Works, 125 Front street, San Francisco.

Assay Office of H. Harris, Silver City, Nevada, April 24, 1869—Messrs. A. S Hallidie & Co.—Gents.:—I received from you three Crucibles of the Morgan make, which I have used since their arrival, and tested by constant use. Since 1847, when in the New Orleans Mint, I have always preferred the Crucible of Dixon's make over Adus, Gautier, and Taunton, Mass. Yours I find to be not alone of more finished make, but to stand double or treble the work of Dixon's Crucibles. The No. 12—the smallest sent—has stood so far 32 meltings, and is as good and sound as when received. Your Crucibles do not scale off like others; and as they are forty per cent. cheaper, I do not see why they should not be preferred by all assayers on account of durability and cheapness. Yours respectfully, H. HARRIS.

On hand and for sale by the Agents,

A. S. HALLIDIE & CO.,

Reading for the Hour.

To Yosemite on Foot.

Some three weeks since six young gentlemen, members of the San Francisco High School, decided to spend their vacation on a visit to Yosemite, the Big Trees, etc. Health, as well as recreation and instruction being in part their object, they resolved to copy after the good old German custom, and make the trip on foot. They have just returned from the trip, highly delighted, and greatly improved in health. They studiously avoided all hotels, stages, etc., save the trip from this city to Stockton by steamboat. Each one carried his own blankets and provisions strapped into a knapsack; they camped out, and cooked for themselves all the way. The names of these young gentlemen are as follows: Dwight Huntly, John Stillman, Samuel Hall, Wendell Jackson, William Robinson and Robert Hayne. The example of these young students might be advantageously followed by others. Such a tramp and camping out, is worth for the health of a young man confined all the year to his studies, a dozen trips by stage accompanied with hotel living, especially under the mild skies and dewless nights of a California summer in the mountains.

We regret to learn that another party which started in the same manner and about the same time, from McClure's Military Academy in Oakland, met with a serious mishap in the loss of one of their number,—Master John M. Bennett, of Oakland,—who was drowned in attempting to ford the Mokelumne river. The fording of mountain streams of any considerable volume is always dangerous, especially for young men not accustomed to such wild and swift running water, and should always be avoided on such tramps. The other members of this party, viz.: Frank Tubbs. Chesley Bonestel, Douald Camphell and S. O. McClure, returned safely to their homes.

CHINESE geese are a great curiosity. Farmer Treadway used to own a pair of them. He didn't keep them very long. He swapped them to Boh Sharp for some ducks. These geese have horns on their heads and live to a great age. Treadway swears that his were at least a hundred years old. Anyhow their eggs never would hatch. They have a very peculiar voice—a sort of cross between the sound of a gong and that of a Scotch bag-pipe. That is the reason he was willing to exchange them for Sharp's ducks. By the time Sharp had had them for forty-eight hours the novelty of their peculiar music began to wear off. Gradually he lost interest in them and began to quit inviting people up to see his geese. Then he got disgusted; and finally he sold them to Capt. Winnie. Report says they have driven everything off from Winnie's ranch. If they haven't they will; for when they tune up you can hear them a mile against the wind. They must be the kind of geese that saved the Roman capital. Certainly, when they are in good voice, they can make a noise that is not only strong enough to wake a whole city, but to frighten away all its enemies.—*Carson Appeal.*

THE JEWEL IN TOADS.—Shakespeare and other poets locate this "precious jewel in his head," but they cultivated the flowers of poesy, and were poor observers in the garden. Watching these ugly animals among the squash and cucumber vines, we shall discover the jewel in the stomach, in the shape of a healthy appetite for bugs and worms. The quantity they will devour is enormous. "Their big bellies with fat black bugs lined," proclaim their virtues. Toads are among our best friends, and they should have the full freedom of the garden.

PAYING THEM BACK—CALIFORNIA HORSES FOR ARKANSAS.—The Butte *Record* says that E. H. Gould, Esq., of Moore's Station, in that county, has started a drove of 3,000 horses across the plains for Arkansas. He took them over the mountains by the way of Honey Lake valley. He has long been a heavy stock man, and entertains no doubt of the succes of his venture.

ADVANTAGES OF CRYING.—A French physician publishes a long dissertation on the advantages of groaning and crying in general, and especially during surgical operations. He contends that groaning and crying are two grand operations by which Nature allays anguish; that those patients who give way to their natural feelings more speedily recover from accidents and operations than those who suppose it unworthy a man to betray such symptons of cowardice as either to groan or cry. He tells of a man who reduced his pulse from one hundred and twenty-six to sixty in a few hours by giving full vent to his emotions. If people are at all unhappy about anything, let them go into their rooms and comfort themselves with a loud boo-hoo, and they will feel a hundred per cent. better afterward.

In accordance with the above, the crying of children should not be too greatly discouraged. If it is systematically repressed the result may be St. Vitus's dance, epileptic fits, or some other disease of the nervous system. What is natural is nearly always useful; and nothing can be more natural than the crying of children when anything occurs to give them either physical or mental pain. Probably most people have experienced the effect of tears in relieving great sorrow. It is even curious how the feelings are allayed by their free indulgence in groans and sighs. Then let parents and friends show more indulgence to noisy bursts of grief—on the part of children as well as of older persons—and regard the eyes and mouth as the safety valves through which Nature discharges her surplus steam.

MEAN OLD BOSTON.—Mean men—men of means, mean the same thing. Saving and hoarding codfish aristocracy! History tells us that the Yanks commenced being mean by saving so much out of the "catch" of each fishing-smack, away back in 1840, '50, '60, or somewhere along there, for the purpose of raising a fund for public education; and to this day these prying, meddling, interfering busy-bodies are looking out for the education of every child, regardless of nationality and color, and even go so far as to make it punishable by law for parents or guardians to keep children away from school to peddle, beg or steal. A great outrage on the parents! Boston has those mean English traits lingering in its crooked streets and narrow alleys. It shows too much honor to poets, painters, writers, musicians, scientific men, old Agassiz and such rubbish. Foreigners in the various professions of art speak with grateful memories of Boston, and that doesn't sound well in younger and smaller cities. Then, too, Boston supports the old-fogy institution, Harvard University, and is the rendezvous of Emerson, Longfellow, Holmes, Field, Whittier, Whipple, Motley, and used to be the home of Shaw, Storey, Channing, Everett, Starr King, and those selfish Lawrences, Lymans, Perkins, etc. Mean old Boston!—*S. F. News Letter.*

UTILIZING THE POLECAT.—The odor of the musk of the polecat or skunk is a powerful anti-spasmodic and is said by the N. Y. *Medical Gazette* to be a sure cure for asthma. The liquid, however, is not considered superior in fragrance to cologne. It colors a knife green, when dipped in it. The Indians eat the flesh of the animal as a remedy for coughs and consumption. It makes a savory dish—is tender and delicious. When the animal is designed for the table, the sack containing the musk must be at once removed.

THE Mount Cenis Tunnel will be finished the present year. Since work was commenced upon it, however, such improvements have been made in the machinery for railway traffic over steep grades that it is more than probable that it will prove equally as economical and quite as safe to run cars *over* the mountain as *through* it—especially when the great cost of the tunnel is taken into account.

INDIANS are very skillful in building fires, both in their huts and in the open air. They select dry wood and sticks, and place one end in the fire, while the other ends point in all directions like the spokes of a wheel lying horizontally; they thus keep a moderate but steady fire during the night with an amount of wood that a white man would burn up in an hour. Speaking of the white man they say: "Him big fool—make heep fire and smoke, stand far off, look at him burn, while freeze."

NOW IN PRESS.—Roasting of Gold and Silver Ores, and the Extraction of their Respective Metals without Quicksilver. By G. Kustel, Mining Engineer and Metallurgist; Author of "Nevada and California Processes of Silver and Gold Extraction," and "Concentration of all Kinds of Ore." Illustrated by numerous engravings. Published and sold by Dewey & Co., proprietors SCIENTIFIC PRESS, San Francisco.

HEARTH AND HOME for June 25th contains the first of a series of sketches entitled *Jethro Throop's Night Thoughts*, by John Thomas, who is no other than Petroleum V. Nasby. The great humorist will take an honest country boy to the city, conduct him through the usual experience, and restore him to his home a sadder and wiser boy, satisfied that the peaceful, honest, and temperate life of the farmer is the best and safest life that can be lived. This is a lesson greatly needed at this time, and Nasby is the man to teach it.

☞MARAVILLA COCOA.—*For Breakfast.*—The *Globe* says: "Various importers and manufacturers have attempted to attain a reputation for their prepared Cocoas, but we doubt whether any thorough success has been achieved until Messrs. Taylor Brothers discovered the extraordinary qualities of 'Maravilla' Cocoa. Adapting their perfect system of preparation to this finest of all species of the Theobroma they have produced an article which supersedes every other Cocoa in the market. Entire solubility, a delicate aroma, and a rare concentration of the purest elements of nutrition, distinguish the Maravilla Cocoa above all others. For homœpaths and invalids we could not recommend a more agreeable or valuable beverage." Sold in packets only by all Grocers, of whom also may be had Taylor Brothers Original Homœopathic Cocoa and Soluble Chocolate. Steam Mills - Brick Lane, London. 5v20-1y

TO MINERS, MILLMEN AND METALLURGISTS. Kustel's new work on the Concentration of all kinds of Ores, and the Chlorination Process, for Gold-bearing Sulphurets, Arseniurets, and Gold and Silver Ores generally, is the best and most complete work issued. It contains 120 diagrams, illustrating machinery, etc., which alone are of the greatest value. Price, $7.50, postage paid. Published by Dewey & Co., publishers of the Scientific Press, San Francisco.

IT is a great thing for elderly persons to have their fading eyesight restored to its youthful perfection. This can be done by Muller, who is recognized as the optician of the Pacific coast. His Brazilian spectacles, properly fitted and adjusted, are superseding all others in use. *

ATTENTION TO MINING COMPANIES OF COPPER AND GALENA ORES.—A mining engineer and assayer thoroughly acquainted with practical smelting of lead and copper ores, and competent to put up all kinds of furnaces, wishes employment. References given Please address C. T. MOHRIG, care of Schultz, Fischer & Mohrig, No. 10 Stevenson street, near First. San Francisco. 23v20-1m

DR. HARTMANN, Physician, Oculist and Medical Electrician, cures all diseases of the eye, such as Granulated Eye Lids, Inflammation of the Eye. Opacities of the cornea cured permanently. Also, Paralysis, Rheumatism and all Nervous and Chronic Diseases, and all Female Complaints. 314 Bush street. 25-520.

WE call attention to the new portable gas burner—the only one that can be regulated to any size, flame, and burn without smoke or smell. Equal to any gas at one-fourth the cost. P. J. Philips & Co., 650 Market street, have county rights for sale for this valuable invention; also lamps for sale. No one should be without them who wants a good, cheap and safe light. 21v20-4w

TREATMENT OF REBELLIOUS SILVER ORES, by Charles H. Aaron—a pamphlet of eight pages of concise reading, of practical value to parties interested in the subject. Printed and sold by Dewey & Co., at this office, for 25 cents, post paid.

BUSINESS FORTUNES are often made easily, quickly and legitimately by Patent Rights. We advise both sellers and purchasers to patronize reliable agents only. Weister & Co., patent brokers, No. 314 Bush street, San Francisco, are one of the most honest, reliable firms in the United States. *

LOOK AT THE RUINS.—Aye, look at the ruins of what once were magnificent sets of teeth, to be seen everywhere in society. Look at them, and ask yourself if it is not marvelous that such destruction is permitted, when, by simply using Sozodont, any teeth, however fragile, may be preserved from decay or blemish as long as life lasts?

"SPALDING'S GLUE" useful in every house.

TO FARMERS.—Stevens & Bro's Egg Boxes, holding 30 dozen, supplied free of charge, by John Gray & Co., No. 210 Clay street, San Francisco, to all customers. The eggs are kept cool and free from moisture and mould, are in no danger of being broken, and require no re-counting. 20v20-3m

New Mining Notices.

Office of Eclipse Consolidated Mining Company, 210 Battery street, San Francisco, June 20th.

The Annual Meeting of the stockholders of this Company will be held on Saturday, July 23d. 1870, at twelve o'clock, M., for the election of Trustees for the ensuing year and the transaction of any other business that may be presented.

ju25-4w SOLON PATTEE, Secretary.

Jennie A. Consolidated Mining Company, White Pine District, Nevada.

Notice is hereby given, that at a meeting of the Board of Trustees of said Company, held on the twentieth day of June, 1870, an assessment of ten (10) cents per share was levied upon the capital stock of said Company, payable immediately, in United States gold and silver coin, to the Secretary, Room 37 New Merchants' Exchange, San Francisco, California.

Any stock upon which said assessment shall remain unpaid on the twenty-fifth day of July, 1870, shall be deemed delinquent, and will be duly advertised for sale at public auction, and unless payment shall be made before, will be sold on Monday, the fifteenth day of August, 1870, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Trustees.

J. M. BUFFINGTON, Secretary.

Office, Room 37 New Merchants' Exchange, California street, San Francisco. ju25

Pogonip Flat Silver Mining Company.—Location of Works: White Pine, Nevada.

Notice is hereby given, that at a meeting of the Board of Trustees of said Company, held on the fifteenth day of June, 1870, an assessment of three (3) cents per share was levied upon the capital stock of said Company, payable immediately, in United States gold and silver coin, to the Secretary, No. 1 Express Building, northeast corner Montgomery and California streets, San Francisco, California.

Any stock upon which said assessment shall remain unpaid on the twenty-third day of July, 1870, shall be deemed delinquent, and will be duly advertised for sale at public auction, and unless payment shall be made before, will be sold on Monday, the eighth day of August, 1870, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Trustees.

T. J. OWENS, Secretary.

Office, No. 1 Express Building, northeast corner Montgomery and California streets, San Francisco. ju25

Mining Notices--Continued.

Cordillera Gold and Silver Mining Company, Chihuahua, Mexico.

Notice is hereby given, that at a meeting of the Board of Trustees of said Company, held on the eighth day of June, 1870, an assessment of fifty (50) cents per share was levied upon the capital stock of said Company, payable immediately, in United States gold coin, to the Secretary, at his office, No. 321 Washington street, San Francisco, California.

Any stock upon which said assessment shall remain unpaid on Saturday, the ninth day of July, 1870, shall be deemed delinquent, and will be duly advertised for sale at public auction, and unless payment shall be made before, will be sold on Monday, the first day of August, 1870, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Trustees.

HENRY R. REED, Secretary.

Office, 321 Washington street, San Francisco. jul1

Evening Star No. 1 Silver Mining Company.—Location of Works: White Pine County, State of Nevada.

Notice is hereby given, that at a meeting of the Board of Trustees of said Company, held on the first day of June, 1870, an assessment of five (5) cents per share was levied upon the capital stock of said Company, payable immediately, in United States gold coin, to the Secretary, at the office of the Company, Room 5, No. 302 Montgomery street, San Francisco, California.

Any stock upon which said assessment shall remain unpaid on Saturday, the second day of July, 1870, shall be deemed delinquent. and will be duly advertised for sale at public auction, and unless payment shall be made before, will be sold on Monday, the twenty-fifth day of July, 1870, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Trustees.

WM. H. WATSON, Secretary.

Office, Room 5, No. 302 Montgomery street, San Francisco, California. ju4

Land Purchasers' Association.—At a meeting of the Board of Trustees of the Land Purchasers' Association, held June 7th, 1870, the following resolution was adopted by unanimous vote:

Resolved, That an assessment of ten dollars per share, gold coin, be, and the same is hereby levied, upon each and every share of the capital stock of the Land Purchasers' Association now held by subscribers thereto; being for the monthly installment falling due and payable June 1st, 1870. Said assessment is payable on or before the thirtieth day of June, A. D. 1870, to JAMES F. CROSETT, Secretary, at the office of the Association, No. 304 Montgomery street, San Francisco.

Any stock upon which said assessment shall remain unpaid on the thirtieth day of June, A. D. 1870, shall be deemed delinquent, and will be advertised for sale at public auction, and unless payment shall be made before will be sold on the thirtieth day of July, A. D. 1870, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

J. F. CROSETT, Secretary.

Office, 304 Montgomery street, San Francisco. ju18

Office of the Placer Gold Mining and Canal Company.—Location of Works: Township No. Six (6), County of Placer, State of California.

Notice is hereby given, that at a meeting of the Trustees of said Company, held on the eleventh day of June, 1870, an assessment (No. 2) of two dollars ($2) per share was levied upon the capital stock of said Company, payable immediately, in United States gold coin, to the Secretary, at the office of the Company, No. 204 Montgomery street, San Francisco, California.

Any stock upon which said assessment shall remain unpaid on Tuesday, the twenty-sixth day of July, 1870, shall be deemed delinquent, and will be duly advertised for sale at public auction, and unless payment shall be made before, will be sold on Tuesday, the sixteenth day of August, 1870, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Trustees.

C. S. HALEY, Secretary.

Office of Company, No. 204 Montgomery street, San Francisco, California. jul8

Office of Silver Sprout Mining Company, 408 California street, San Francisco, June 2d, 1870. NOTICE.—The annual meeting of the stockholders of the Silver Sprout Mining Company, will be held at the office of the company, No. 408 California street, San Francisco, on Tuesday, the twenty-eighth day of June, 1870, at 12 o'clock M., for the election of Trustees to serve for the ensuing year, and for the transaction of such other business as may properly come before the meeting. [ju1-1m] T. B. WINGARD, Secretary,

Land Purchasers' Association—Office, No. 304 Montgomery street, San Francisco.

NOTICE.—There are delinquent upon the following described stock, on account of assessment levied on the third day of May, 1870, for the monthly installment due May first, 1870, the several amounts set opposite the names of the respective shareholders, as follows:

A VALUABLE BOOK FOR INVENTORS AND ARTISANS.—Dewey & Co., publishers of the SCIENTIFIC PRESS and Patent Agents, have just issued a neat little volume of over five hundred well executed cuts of the principal mechanical movements known. These useful representations of the various appliances of power are printed side by side with explanatory notes, which makes the subject clear to every reader. Such a book should be in the hands of every mechanic, and form part of every public school library. It is a handy book, and cheap enough for every farm, shop and factory. Sent to any address from the SCIENTIFIC PRESS office, postpaid, for $1.—*New Age.*

Latawana Mining Company—Near Hamilton City, White Pine, State of Nevada.

Notice is hereby given, that at a meeting of the Board of Trustees of said Company, held on the second day of June, 1870, an assessment of fifteen cents per share was levied upon the capital stock of said Company, payable immediately, in United States gold and silver coin, to the Secretary, at 614 Merchant street, Room 26, San Francisco, California

Any stock upon which said assessment shall remain unpaid on the fourteenth day of July, 1870, shall be deemed delinquent, and will be duly advertised for sale at public auction, and unless payment shall be made before, will be sold on Saturday, the sixth day of August, 1870, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Trustees.

A. MARTINON, Secretary.

Office, 614 Merchant street, Room 26, San Francisco, California. ju11

TARRANT'S
SELTZER
APERIENT.

DON'T FOLLOW BLIND GUIDES.—The sick never lack advisers. Every friend has some new remedy to propose. The result is that the stomach of many an invalid is converted into a sort of medicinal cess-pool, in which powerful drugs are continually seething and fermenting. The effect of this experimental treatment in dyspepsia and bilious complaints is frightful. The simpler the medicine the more readily it assimilates with the animal fluids, and of all preparations in use for indigestion and biliousness, Tarrant's Effervescent Seltzer Aperient, prepared after Nature's formula, and absolutely identical with the waters of the famous German Spa, is indisputably the best.

SOLD BY ALL DRUGGISTS.

DESIGNS AND PLANS

— OF THE —

NEW CITY HALL

— OF —

SAN FRANCISCO.

Office Board of City Hall Commissioners, southeast corner of Sacramento and Montgomery streets, San Francisco, June 22, 1870.

The Board of City Hall Commissioners hereby give notice that they will be prepared to receive at their office, on or before the FIRST DAY OF NOVEMBER NEXT, designs and plans for the new City Hall of San Francisco.

The Commissioners, in order to obtain the very best design and plan, invite the fullest competition among architects, and to this end have resolved to offer the following premiums:

First—For the design and plan selected and adopted	$2,500
Second—For the second best design and plan	2,000
Third—For the third best design and plan	1,500
Fourth—For the fourth best design and plan	1,000
Fifth—For the fifth best design and plan	500

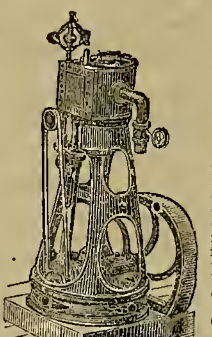
The premiums payable in City Hall warrants.

As a guide to architects in the preparation of the designs and plans, the Commissioners have prepared a pamphlet containing full instructions and suggestions, as well as the terms and conditions upon which the premiums will be awarded.

Pamphlets can be had on application at the office of the Commissioners.

Any design or plan in which the requirements of the Board, as set forth in the printed instructions, have not been reasonably complied with, will be rejected from the competition.

P. H. CANAVAN, Chairman,
JOS. G. EASTLAND,
CHAS E. McLANE,
26v20-4m City Hall Commissioners.



RIDER'S

Automatic Cut-off

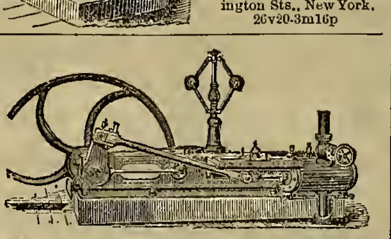
Vertical Engines

Manufactured by the

Albany St. Iron Works,

NEW YORK.

These Engines are simple, compact and durable, and in point of economy of fuel and space are excelled by none, and are cheaper than any other first-class cut-off Engines in the market. Descriptive pamphlets and price lists mailed free on application to the proprietors, HANDREN & RIPLEY, Corner Albany and Washington Sts., New York. 26v20-3m16p



RIDER'S GOVERNOR CUT-OFF ENGINE,

Manufactured by the DELAMATER IRON WORKS, WEST THIRTEENTH ST., NEW YORK. The prominent features of this engine are: Economy equal to any; perfect regulation of speed by cut-off; entire absence of delicate or complicated mechanism; simplicity of design and non-liability of derangement; requiring no more care than common engines. NOTE.—This improvement can be applied in many cases to existing engines. Pamphlets sent on application. 26v20-3m16p

Sheffield Scientific School

Of Yale College, New Haven, Conn.

This department of Yale College, instituted in 1840, and endowed with the National Land Grant in 1866, furnishes advanced instruction in the various branches of Mathematical, Physical, and Natural Science.

The School is under the direction of the President of the College, a Board of thirteen Professors in differe special ties, and six assistant instructors.

Regular courses of study, leading to the degree of Bachelor of Philosophy, conferred by Yale College, are arranged as follows: 1—CHEMISTRY AND MINERALOGY. 2—CIVIL ENGINEERING. 3—MECHANICAL ENGINEERING. 4—MINING ENGINEERING AND METALLURGY. 5—AGRICULTURE. 6—NATURAL HISTORY AND GEOLOGY, and 7—SELECT COURSE.

Advanced students are also admitted to optional courses, and if already College graduates, are received as candidates for the degree of Doctor of Philosophy.

Tuition, $125 per year of forty weeks.

The Libraries, Museums, Laboratories and Apparatus accessible to students, are varied and extensive.

For copies of the Annual Circular and Report, letters may be addressed to the "Secretary of the Sheffield Scientific School," New Haven, Conn. v16-1y16p

Oil Cake Meal.

THE BEST FEED KNOWN
FOR LIVE STOCK.

We desire to call attention to Oil Cake Meal, which we are now manufacturing. No description of feed so greatly promotes the health of animals as Oil Cake Meal, and we urgently request all engaged in the dairy business, raising and fattening stock, or wool growing, to give it a trial, feeling confident that they will find it of very great value. By those who have used it thoroughly, ONE pound is pronounced to be equal to two pounds of Corn Meal, and in the United States Government Report of the Department of Agriculture for 1865, it stands in the following relation to other feeds as to the percentage of flesh produced from a hundred pounds of feed, viz: Indian Corn Meal, 11 per cent.; Barley Meal, 13 per cent.; Oat Meal, 18 per cent.; Oil Cake Meal, 22 2-100 per cent. For life-sustaining properties to all stock exposed to sudden changes of weather or overdriving, it has no equal.

For MILCH COWS it is particularly valuable, increasing the quantity of milk and improving its quality to a far greater extent than any feed known. A suitable quantity for them at the commencement is one quart in the morning and one quart at night, either alone or mixed with any other food; generally mixed with the mash of bran, slops, roots, or cut feed of any kind. It improves it to soak it for six or eight hours, the effect being to increase its bulk two or three times. The quantity can be increased gradually, according to the effect produced—ordinarily not exceeding three or four quarts per day.

FOR BEEF CATTLE it has fattening properties which cannot be found in any other feed—the beef always being more tender and juicy, and of a much finer quality than when fattened on any other feed, and no feed known will so quickly prepare animals for market as Oil Cake Meal.

FOR HORSES a small quantity given daily promotes their health, and is especially valuable for them when chilled or injured from over-driving. It is one of the best remedies known for Horses subject to the Heaves or Rheumatism, and greatly increases the cleanliness and evenness and glossiness of the hair.

FOR SHEEP there is no article of food known that produces such fine mutton or so promotes the growth of wool. A small quantity given to chilled Cattle or Sheep will keep them alive and greatly increase their warmth and vitality.

At present price ($25 per ton) it is the cheapest feed in market. It is now selling in New York at $42 per ton gold; at $50 per ton in England, where it has been proven for a long time to be in every respect the most profitable feed known for stock of all kinds—one ton being fully equal to three tons of bran.

The increasing demand for this meal from those on this coast by whom it has been thoroughly tested, has induced us to increase our facilities for its manufacture, and we are now fully prepared to furnish it in quantities as may be desired. For sale by the Grain and Feed Dealers, and at the manufactory, King street, near Third. All orders will receive prompt attention. Address—

Pacific Oil and Lead Works,
Nos. 3 and 5 Front St., San Francisco.

Greatest Discovery Ever Made.

MR. J. W. MAC, while a resident in New Zealand, was so afflicted with the RHEUMATISM, that for years he was completely crippled and unable to attend to business. The symptoms were of the worst type—knees painful and swollen, with sinews contracted; shoulder, arm and hand rendered useless, and accompanied with continued excruciating pain. While in this state of suffering, he got acquainted with a native of the country, who applied to the parts affected a composition spread on coarse canvas, the properties of which were so wonderful that in a short time all the pain left him, the swelling disappeared, his sinews relieved, and he was able to resume his usual avocations. So effectual has been the remedy, that to this day he has enjoyed perfect health, without the slightest return of his former complaint. Knowing the great blessing such a remedy would be to those afflicted with this painful disease, he with great difficulty and expense obtained the secret of preparing the Plaster; and during the many years MR. MAC has applied these Plasters in New Zealand, Tasmania, New South Wales, and this city, their effect has been marvelous, giving to the most painful and long-standing cases sure and certain relief. The most incredulous will be convinced by referring to these persons: B. W. Owens, 405 Front street; F. B. Alderson, Traveling Agent for Dewey & Co., 414 Clay street; James Flynn, 519 Mission street: Michael Gorman, No. 6 Front street; Mrs. W. S Wright—late of Gilmore House—518 Folsom street, now agent at Virginia City; E. Shenley, corner Montgomery and Filbert streets; W. M. McLeod, Depository merican Tract Society, 557 Market street, and a host of others, who all bear testimony to the unparalleled healing powers of J. W. MAC'S (rightly termed Magic) Plasters, for the cure of Rheumatism, Gout, Weak Loins, Tender Feet and Neuralgia. J. W. MAC may be consulted at his office, rooms Nos. 34, 35 and 36, 128 Kearny street, San Francisco, between the hours of 9 to 12 A. M., 2 to 4 P. M. and 7 to 9 P. M.

18v20-3m

The Latest, Cheapest, and Most Durable.

CRANDALL'S

PATENT SPRING BED.

This invaluable Spiral Spring Bed combines all the good without any of the bad features of the common spring mattrass. It consists of a framework of springs resting on a bed of stronger springs, thus giving it nearly double the elasticity of any other bed. The springs are self-supporting, each pair being independent of the others, and consequently the tendency to sag or incline toward the middle is avoided. Unlike other spring beds, they require no upholstering, and, of course, afford no harbor for fleas or dust. The medical faculty have pronounced it the best Bed in use. It commends itself to those who have examined and used it. They invariably pronounce Crandall's Patent the best Spring Bed ever offered to the public.

These Beds are on exhibition and for sale at the Cabinet Warerooms of

JOHNSON & BEST,

No. 413 PINE STREET, RUSS BLOCK,

Between Montgomery and Kearny. Also at

639 Market Street, near New Montgomery.

Beds guaranteed to give satisfaction

Or the money will be refunded.

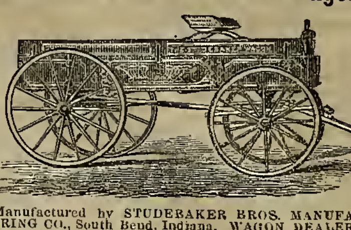
Rogers, Esq., residence Oakland Point, office 16, 17 and 18 California Market; W. Zelhcer, Esq., residence 613 Geary street; James Dexter, Esq., office 430 Sansome street; John A. Roth, Esq., residence 106 Silver street. James Connor, Esq., Alameda.

N. B.—Responsible persons can have one on trial.

S. B. SNEDAKER & CO.,
21v20-6w Agents for San Francisco.

The Celebrated Studebaker Wagon,



Manufactured by STUDEBAKER BROS. MANUFACTURING CO., South Bend, Indiana. WAGON DEALERS, there are nine reasons why you should buy the above Wagon:

FIRST.—They are made of the best selected INDIANA TIMBER, thoroughly seasoned under cover.

SECOND.—They are made by experienced mechanics.

THIRD.—The lightest running and most durable Wagon in the market.

FOURTH.—Their Thimble Skeins never break, while all others do.

FIFTH.—Most uniform and best proportioned Wagon in the market; any part of one will fit another, while other makes will not

SIXTH.—The only Wagon in which the SLOPE SHOULDER SPOKE is used; hence they have the best Wheel, which is actually the foundation of the Wagon, and should be carefully examined by persons buying.

SEVENTH.—They are sold only by responsible parties, and every Wagon is warranted to give entire satisfaction,

EIGHTH.—Because Teamsters will tell you they are the best Wagons, for all purposes, on the road.

NINTH.—Last, but not least. Studebaker Brothers are practical men, attend to their business personally, and do not entrust it entirely to foremen, as is generally the case in large factories; hence the superiority of their work over all others. Sold by

Rooms: No. 12 Montgomery street, opp Lick House. Hours from 10 to 3. ☞ Se habla Español. On parle Français.

Hold Your Horses.

The subscriber has the pleasure of announcing to the public a new, novel, cheap, and useful invention, which every person owning a horse needs for every-day use. It is called a "HORSE-HITCHER." You need no longer have your shade trees and fences ruined by hitching to them, nor the street of the city blockaded by posts. With this arrangement any horse may be left in the street or field with perfect safety. TRY, and you will hold fast, because you will find him GOOD. Agents wanted everywhere. This invention is one which pays industrious Agents large profits. It is a new thing, never having been offered to the public before. No charge is made for boxing, and no order for less than one dozen is sent, at $10, prepaid or C. O. D., unless a sample, which will be sent on receipt of the retail price, $1.25. One agent sold in three weeks over 500. State, County and Town Rights for sale. Apply to ANTHONY JACKSON, LA CROSSE, WIS. P. O. Box 409. 25v20-1m

Wood Cutting & Splitting Machine.

This Machine is made of cast iron, constructed without saw, *only with* "STEEL KNIVES," and by removing half a dozen bolts, is easily taken apart or put together in a few minutes; will cut and split more than 40 cords of fire-wood per day, hard or soft wood, as using for stoves and railroad, and requiring but two men to tend it. Can be driven by steam or horse power. The patentee offers the largest inducements to foundrymen and dealers in patents, for the purchase of State and County Rights, and for the manufacture and sale of these Machines in all parts of the country. Secure the right soon. Apply to ANTHONY JACKSON, LA CROSSE, WIS, P. O. Box 409. 25v20-1m

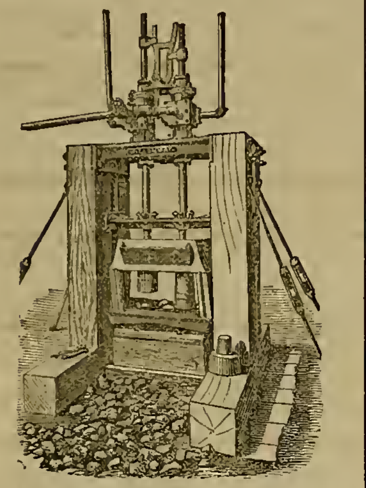
THE WILSON
Patent Steam Stamp Mill.



This extraordinary Mill, now so justly popular in the East, is now offered to the miners of the Pacific Coast. Having been in operation now for about eighteen months, the Company feel confident that the

WILSON STEAM STAMP MILL,

For Durability, Efficiency,

AND ECONOMY OF WORKING,

HAS NO EQUAL.

The Wilson Steam Stamp Mill is the only Steam Mill that has had the severe ordeal of practical working, and proved itself eminently successful. It is now in operation in several of the Eastern States and Territories, and gaining an envious popularity. The whole machine is so simple as to be readily understood by the most ordinary minds. In fact, its simplicity is its durability. The expense of crushing rock or cement with this Mill is less than one-half the expense of any other Stamp Mill, and less than one-half the cost. For further particulars inquire of

A. BICKNELE, Agent,
Novada City, California,

Or of THE WILSON STEAM STAMP MILL CO., 326 Walnut street, Philadelphia, Pa.

NOTICE.—All persons are hereby warned not to manufacture or use any Steam Stamp Mills that are an infringement on the Wilson Patents, as they will be prosecuted to the utmost rigor of the law.

F. R. WILSON,
20v19-tf Supt. W. P. S. S. M. Co., Philadelphia.

VARNEY'S
PATENT AMALGAMATOR

These Machines Stand Unrivaled.

For rapidly pulverizing and amalgamating ores, they have no equal. No effort has been, or will be, spared to have them constructed in the most perfect manner, and of the great number now in operation, not one has ever required repairs. The constant and increasing demand for them is sufficient evidence of their merits.

They are constructed so as to apply steam directly into the pulp, or with steam bottoms, as desired.

This Amalgamator Operates as Follows:

The pan being filled, the motion of the muller forces the pulp to the center, where it is drawn down through the aperture and between the grinding surfaces. Thence it is thrown to the periphery into the quicksilver. The curved plates again draw it to the center, where it passes down, and to the circumference as before. Thus it is constantly passing in a regular flow between the grinding surfaces and into the quicksilver, until the ore is reduced to an impalpable powder, and the metal amalgamated.

Setlors made on the same principle excel all others.—They bring the pulp so constantly and perfectly in contact with quicksilver, that the particles are rapidly and completely absorbed.

Mill men are invited to examine these pans and setlers for themselves, at the office, **229** Fremont street,
1vi San Francisco.

TO MILLMEN.

FOR SALE CHEAP.—A 10-stamp mill complete; engine about 35 horse-power; cylinder 12-inch bore and 30 inch stroke; boiler 16 feet long and 48 inch diameter; weight of stamps complete, 650 pounds. The whole is as good as new; has only been running four months. Will sell either engine or battery separate, and deliver it on the railroad at Auburn if required. For particulars apply to W NAGEL, 702 Bush street, San Francisco, or to MOUNTAIN CO., Forest Hill, Placer county. 16v20-3m

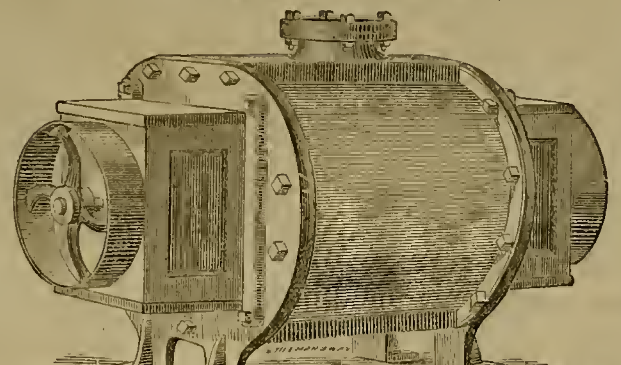
ROOT'S PATENT FORCE BLAST ROTARY BLOWER.

MANUFACTURED BY KEEP & BARGION,

At the Globe Iron Works, Stockton, California.

Awarded the First Premium at the Paris Exposition.



Patented Nov. 1st, 1864; July 24 1866; and Oct. 9, 1866.

ADAPTED

FOR

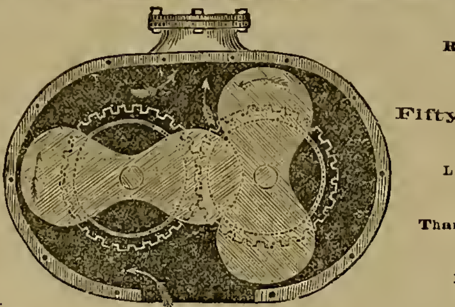
Smelting,

Foundry,

Mining

and

Steamships.



REQUIRES

Fifty Per Cent.

LESS POWER.

Than any Blower

Now in use.

One of these Blowers may be seen on exhibition at W. T. Garratt's Brass Foundry, corner of Mission and Fremont streets. They are also in use at the Almaden Quicksilver Mine; Gridley's Foundry, Gold Hill, Nevada; Ætna Iron Works, San Francisco, and many other places.

CAUTION.—Purchasers will find it to their advantage to apply direct to the Stockton Agency, as certain parties, not authorized to manufacture the Blower, have put in the market machines of inferior construction, which do not answer all the requirements of the genuine article.

Quartz, Saw and Grist Mill Irons, Steam Engines, Horse Powers, High and Low Pressure Steam Engines, Steamboats and Propellers, made at short notice.

List of Patents

Issued to Inventors in the Pacific States and Territories.

Amalgamator, C. C. Stevenson........ 238
Amalgamator and Concentrator, J. Scott...... 376
Anchor, A. H. Law........ 361
Animal Trap, A. Brown.. 9
Animal Trap, J. H. Lord. 303
Apparatus for Blasting Logs, M. Cnoko........ 328
Artificial Flower Manufacture, C. E. Howard. 169
Baling Press, J Marsters 417
Ball and Socket Joint, R. R. & J. Craig........ 24
Bed, Extension, F. Menzer........ 256
Bedstead, F. Menzer..... 104
Blind Stile Boring Machine, A. M. Winn, J. Kindleberger & W. A. Arnold........ 24
Boat-Detaching Apparatus, J. Ross........ 153
PAGE.
Boiler Furnace, J. A. T. Overend........ 328
Bolster and Axle-Bed Plates, J. Henry..... 216
Brake for Carriages, B. F. Lect........ 24
Breech Load'g Ordnance, A. F. Potter........ 361
Buildings, J. Touaillon... 153
Camera Stand, W. W. Dames........ 288
Cane-seat Chair, C. M. Robr........ 433
Carbureting Air, B. Pilkerton........ 24
Carriage Axle, Geo. A. Lloyd........ 240
Carriage Wheel Hub, A. F. Cooper........ 328
Caster for Sewing Machines, J. M. Vessey.... 240
Carriage & Railroad Car Wheels, A. F. Cooper... 401
Coal Preparation for Smelting, W. J. Lind... 41
Coal, Using Colorado and Similar for Smelting, W. J Lind........ 41
Composition for Pipes, W. P. Kirkland........ 101
Coupling for Cars, A. S. Hart........ 9
Cultivator, A. B. C. Nusbaum........ 153
Curtain Fixture, J. & W. Turnbull,........ 168
Cut-off, Variable, M. C. Taylor........ 9
Dental Apparatus, J. A. Loomis and C. F. Moll. 288
Desulphurizing Ores, E. A. Burns........ 182
Distillation in Vacuo, F. Gutzkow........ 401
Dove-tailing Machine, E. Heath........ 433
Dredging Machine, W. D. Robertson........ 376
Dress Protector, F. Wittram........ 216
Drill, A. Blatchley........ 169
Driven Well, I. Trump... 104
Dynamometer, J. W. Sutton........ 9
Egg-Beater, F. Krandelt 153
Engine, Rotary Steam, G. H. Pond........ 41
Excavating Machine, A. W. Hansen........ 401
Extracting Copper from its Ores, N. Haskell..... 216
Fence, H. H. Murgeson.. 153
Foundation for Buildings, A. F. Cooper........ 169
Frame for Street Lamps, J. Radston........ 361
Furnace and Condenser for Reducing Volatile Ores, R. F. Knox & Jos. Jos. Osborn........ 433
Gas Manufacture, E. P. McCartney........ 361
Gate Latch, J. W. Still... 376
Gold Collecting Apparatus, A. F. W. Partz...... 41
Gold-Saving Apparatus, G. C. Schofield........ 345
Grain and Straw-Carrying Attachment for Separators, B. & B. J. Jackson........ 182
Grip Pulley, A. S. Hallidie........ 153
Hair Medicine, A. J. Fletcher........ 288
Harvester and Thresher, D. Hallowell........ 89
Harvester-Cutter, F. Wittram........ 24
Hinge, Spring, James Sidwell........ 433
Horse-shoe, G. Copeland. 328
Hydraulic Nozzle, A. Harris........ 24
Knob for Safe Doors, J. G. Kittredge........ 288
Lasting Machine, K. Grassau........ 256
Ledger-Index, C. A. Fitch and W. O. St. John...... 216
Lifting Jack, L. P. Oarein 256
Lounge and Bed, A. Hansen........ 41
Lubricating Sleeve, G. A. Lloyd........ 9
Mainspring Barrel Attachment for Watches, O. L. Eliason........ 328
Medical Compound, P. Lee and L. Matthews........ 240
Medicine for Nervous Diseases, J. F. Smith....... 57
Medicinal Beverage, L. F. Lastreto........ 216
Metals, Separating and Refining, C. H. Eysler.. 433
Mortising Machine, J. Cox 89
Needle, J. W. Donaldson and D. Sheets........ 303
Needle and Arm for Sewing Machine, M. P. Carpenter........ 89
Needle for Sewing Machine, H. G. Suplee..... 104
Needle for Sewing Machine, J. L. Boone...... 153
Needle for Sewing Machine, M. P. Carpenter. 401
Nut-Locking Washer, R. Rutter........ 401
Oar, W. J. Hough........ 73
Ore Disintegrating Apparatus, A. B. Paul........ 256
Ore Feeding Machine, C. Stetefeldt........ 169
Ore Separator, T. Bates.. 328
Packing for Stationary Joints, H. T. Lee........ 303
Paddle Wheel, A. Winga d 104
Padlock, G. K. Farrington 153
Pencil Holder, A. J. Hall. 256
Pencil Sharpener, H. Burgess........ 345
Percussion Fuse, W. Gardner........ 401
Photographs, Coloring, R. Winter........ 433
Piston and Piston Packing, O. Collier........ 24
Piston-Rod Packing, H. T. Lee........ 288
Platform Attachment for Grain Separators, J. Whitesido........ 67
Plow, Gang, E. E. Gore.. 24
Plow, Gang, J. & S. Cox.. 121
Plow, Gang, S. Welch..... 104
Plow, Gang, G. R. Duval. 169
Plow, Gang, J. Price..... 216
Plow, Gang, J. W. Sursa. 256
Plow, Gang, P. H. Flansburgh........ 345

Best Illustrated Newspaper

— FOR —

PACIFIC COAST READERS.

The Scientific Press,

[ESTABLISHED 1860.]

A large Illustrated, Practical Scientific Home Journal, devoted to

Mining, Farming, Mechanic Arts

AND INDUSTRIAL PROGRESS.

Each weekly issue contains 16 pages (size of Harper's Weekly), except our double sheet, published on the first week of each month, which comprises 24 pages. It is ably edited, and contains, in concise and desirable form, all the most important discoveries, inventions, improvements and developments in the various branches of Science, Mechanic Arts and Industrial Pursuits, interesting to all intelligent readers on this coast. We make a live paper for the times, using plain, comprehensive language, giving information which cannot be had from books, or so readily and cheaply obtained from any other source. Each number often furnishes profitable hints to the reader worth many times its annual subscription price. Please examine sample copies and subscribe at once, and you will not regret it.

Terms, for six months, $2.50; one year, $4—payable in advance. Sample copies of the PRESS and illustrated Patent circulars sent free on receipt of postage stamp.

DEWEY & CO.,
Publishers and Patent Agents, No. 414 Clay street, San Francisco.
